Leeds and West Riding Medico-Chirurgical Society.—A meeting of this society was held on Nov. 13th, Dr. W. H. Cheetham being in the chair.—Mr. A. S. F. Grünbaum made some remarks on the principles underlying the use of the various bacterial vaccines, pointing out that toxin bacteria usually required antitoxic serum and endotoxin bacteria generally required vaccine for the efficient treatment of their respective infections. He recommended prophylactic inoculation of individuals of tuberculous diathesis when young and before the appearance of any symptoms.—Dr. Myer Coplans made some remarks on Points in Comparative Pathology. He showed specimens of tuberculosis produced experimentally in the guinea-pig, comparing the *centripetal* progress of the disease with those forms found naturally in the pig, while contrasting the *centrifugal* progress of the disease in lactating cows in which involvement of the pre-lumbar and supramammary glands nearly always preceded the onset of tuberculous mastitis, which, when present, should be regarded as a sufficient warrant for the animal's destruction. Sections illustrating the pathology of Johne's disease (enteritis of cattle) were shown and described. Smears of pus showing the cryptococcus of Revolta were shown and the differential diagnosis between glanders of the horse and epizootic lymphangitis was discussed. Macroscopic and microscopic specimens of the anthrax purple reaction as applied to animals naturally dead from the septicæmic form of the disease were exhibited and the pathological and legal aspects of the reaction were noted.—Dr. E. F. Trevelyan and Mr. R. G. Hann showed the Viscera from a case of Acute Phosphorus Poisoning.—Mr. H. Littlewood showed: 1. A specimen removed

THE LANCET.

LONDON: SATURDAY, NOVEMBER 28, 1908.

Fifty Years of the General Medical Council: Progress and Retrospect.

ON Tuesday, Nov. 24th, there opened the eighty-eighth session of the "General Council of Medical Education and Registration of the United Kingdom," and the session is a jubilee one. For rather more than 50 years ago—to be precise, upon August 2nd, 1858—the body with the above somewhat cumbrous title came into existence "by the Queen's most Excellent Majesty, by and with the Advice and Consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled and by the authority of the same." The object of the Act with the above preamble was not, as many persons both within and without the medical profession imagine, so much to benefit that profession but to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. We have made this statement very many times, but hardly a week goes by without the receipt of some communication, in response to which we have to point out that the General Medical Council has neither the powers nor the mission to act in the way desired. The ability to make a differential diagnosis between qualified and unqualified men is, as the Act states, "expedient," but in many cases laymen do not seem yet to concern themselves much as to whether a practitioner is qualified or unqualified. The resulting abuses are, however, under serious consideration, and the thinking members of the public are on the side of reform. The progress of medicine has determined them to be so. The 50 years which have elapsed since the passing of the Medical Act of 1858 have seen far-reaching and most important changes in the science and art of medicine and in the teaching of the same. Bacteriology, pathology, etiology, the physiological or biological processes with which are concerned the subjects of opsonins and of vaccine therapeutics have opened up new regions for research and have trebled the armament of medical men in the fight against disease. The medical student of to-day is no longer the type of man described by DICKENS, THACKERAY, and ALBERT SMITH, but a serious-faced youth oppressed with the burden of a five years' curriculum and such an infinity of subjects to be learned that the five years prove quite inadequate. Sir DONALD MACALISTER in his presidential address to the Council, which we publish this week, made no attempt to deal with the vast changes which have taken place since the Council was instituted. Nor shall we. No one could have told the story better than the President of the General Medical Council, but his restraint, his determination to be silent rather than to use up valuable time, must meet with universal approval.

Now although the general standard of knowledge and of work is to-day far higher than that of 50 years ago, we of to-day should remember the debt that we owe to those who have laboured in the same field before us. There is no greater incentive to the medical man of to-day to walk humbly and earnestly and to do his best to add something to the knowledge of his profession than to consider the bygone worthies of medicine. Every medical man should have a hobby and one of the most pleasant and profitable hobbies is the study of the history of medicine. This study may either be pursued at first hand, which takes considerable time, or it may be carried on simply by absorbing the labours of others. To those who care to take their historical studies easily we can commend a book which has recently appeared—one, moreover, written by one of the most cultured and able physicians of to-day, who worthily holds the post of Regius Professor of Medicine in the University of Oxford. In "An Alabama Student and other Biographical Essays"[1] Professor W. OSLER recalls to our minds such men as THOMAS DOVER, LOCKE the philosopher who was also a physician, BEAUMONT, HARVEY, Sir THOMAS BROWNE, and the Alabama student whose name was JOHN Y. BASSETT. The Alabama student was a man whose example is one for all time so far as concerns his burning desire for knowledge. Of such stuff are made the FARADAYS, the VELPEAUS, and all who have struggled with success to learn. BASSETT practised in Alabama in 1835, a date at which that state was, if not exactly a wilderness, at least but sparsely populated. He had studied at the Washington Medical College and had evidently learned that great lesson, how to learn. So consumed by a desire for knowledge he left his wife and children, not without a hard struggle, and set out for Europe, and above all for Paris, that lodestone of all medical men in the former half of the last century. Arrived in Paris he attached himself to VELPEAU for teaching in surgery and anatomy and with true singleness of heart he again began dissecting. The student of to-day will feel a not unnatural envy when he reads BASSETT'S statement that a subject cost six francs and the body of a child only 40 sous. In a letter to his wife he gives an interesting account of the anatomical school at Clamart, a school which still exists and concerning which the present-day French students have recently been agitating. Before very long his industry met with its reward, for VELPEAU appointed him as his *externe*. BASSETT apparently returned to Alabama after a year's study in Europe. Another notable American physician was BARTLETT who, after study in Paris, brought out in 1842 a work on fevers in which the differentiation between typhus and typhoid fever was clearly laid down some years before the work of JENNER and MURCHISON appeared in this country. THOMAS DOVER is a shining example of the "all-round" man of former days, for he started in life as a buccaneer and in 1712 was one of the discoverers of "Robinson Crusoe." In 1721 he was admitted a Licentiate of the Royal College of Physicians of London and in 1732 he published a work on medicine of a popular nature. In this book he describes the celebrated powder which is still one of the most valued remedies that we have. DOVER'S doses, produce punched-out sores. The note was also discussed by the President, Dr. F. W. B. Young, Dr. E. T. Davies, Dr. S. M. Whittaker, and Dr. J. Lloyd Roberts.—Mr. G. P. Newbolt read a paper on Suprapubic Prostatectomy. He advised operation in the following conditions: (1) complete retention and catheter life in otherwise healthy men; (2) frequent micturition rendering life unbearable and coming on at an early age; (3) profuse hæmorrhage from the prostate and recurring at frequent intervals; and (4) occasional retention with difficulty in the passage of, or inability to pass, a catheter. He did not advocate the operation in malignant disease. He considered that any after-trouble in the way of stricture was due to removal of the membranous urethra.—Mr. F. T. Paul considered that the operation was very remarkable in the results derived from it. In performing the operation he made as small a wound in the bladder as he could work with. He commenced enucleation within the neck of the bladder. If hæmorrhage occurred after the operation he removed the tube when, as a rule, the bleeding would stop. He never operated in cases where he considered the enlargement to be malignant.—Mr. W. Thelwall Thomas believed that the mortality would in the future be lessened by operating earlier in the condition. He always made a curved transverse incision and employed air distension of the bladder. Recently he had employed perineal drainage, as suggested by Lynn Thomas, and was very pleased with this improved method.—The paper was also discussed by the President, Dr. Davies, Mr. D. Douglas-Crawford, and Mr. R. A. Bickersteth.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Nov. 13th. Mr. Edward Sergeant delivered his presidential address upon County Health Administration. After giving a short historical account of the evolution of the county medical officer of health, the President dealt with the various public health matters with which county councils are concerned. He described at some length the powers possessed by county councils with respect to the prevention of the pollution of rivers and pointed out that certain trade pollutions, such as those derived from dye, print, and bleach works, chemical works, tanneries, paper-making, woollen works, and silk works, were amenable to chemical and mechanical remedies which might be applied without interfering with manufacturing interests. He instanced the "Magma" process for recovering crude oil from the soap-suds used in dyeing operations and wool washing. In the indigo dyeing trade the spent vat liquors and wash waters after settlement gave a sludge containing so much indigo that it could be profitably re-used. In the manufacture of soap the spent lees were concentrated and distilled and the glycerine, which at one time was turned into the rivers, was now recovered. He considered that crude sewage should not be discharged into the open sea at low-water mark or into an estuary, more especially if the tidal currents were not sufficiently strong to remove or to dissipate the polluting matters without fear of their return. In the case of an estuary the sewage might be carried to sea very slowly and if discharged on the ebb tide might be carried only a short distance before it was driven back by the flood, and so oscillate backwards and forwards, causing a dangerous nuisance. Upon the vexed question of isolation hospital accommodation the President said that in his opinion a scarlet fever patient had a much better chance of recovery in an isolation hospital than in a cottage. He quite agreed that hospital isolation of scarlet fever patients had not quite answered the expectations that had been held out but he thought that no efficient sanitary authority could do without it. The non-removal policy had many attractions for parsimonious authorities, but he considered it wrong to endanger the health of neighbouring districts while engaged in the hopeless attempt to procure isolation in the ordinary dwellings of the working classes. In his remarks upon the administration of the Sale of Food and Drugs Acts he said that it was a grave reflection upon the Central Government that milk, the most important form of food so far as infants were concerned, should still continue to be subjected to frequent adulteration. The standard set up by the Board of Agriculture and Fisheries was, in his opinion, a good one, but its value was largely neutralised as it merely raised a presumption until the contrary was proved that the article was not genuine. He regretted that it was becoming increasingly difficult to obtain convictions in cases of alleged milk adulteration, and occasionally cases were dismissed by the magistrates even though no defence had been raised. In order to avoid such difficulties he considered that a fixed universal standard of genuineness should be adopted below which the sale of milk should be prohibited.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 20th, Dr. J. R. T. Conner, Vice-President, being in the chair.—Mr. Peter L. Daniel read a paper on the Treatment of Tuberculosis by Bier's Congestion and Hyperæmic Methods and by Injections of Iodoform Glycerine. He said that if they could mechanically obstruct the lymphatics and venules they were in possession of a valuable means of localising inflammatory processes and of thus protecting the whole body from invasion by bacteria and toxins, and "while limiting the process and protecting the body it permits nevertheless the whole body forces an opportunity to take part in the destruction of the germs." Iodoform glycerine acted in two ways: first, by mechanically obstructing the lymphatics; secondly, by inducing a hyperæmia—the reparative element of inflammation. By such obstruction to the lymph and venous flow a flooding of the diseased area with plasma took place, and however or wherever protective properties were manufactured in the living body they ultimately were conveyed by, and enabled to act through, the medium of the blood plasma; and as the arterial supply to the diseased area was quite unimpeded, this blood plasma charged with protective properties derived from the liver, spleen, marrow, and muscles permitted the whole body processes to be concentrated locally. By Bier's constricting bandage similar results were obtained in a more obvious manner, the essential point in this treatment being obstruction to the venous and lymphatic flow. Bier's methods consisted of (1) constriction by means of an elastic bandage; (2) suction by means of a suitable cupping glass; and (3) hot dry air. The constriction and suction produced lymphatic and venous congestion, but the hot air was said to induce an arterial hyperæmia. The constriction method, where it could be used, was the best method. The bandage used was made of elastic webbing, from 2 to 2½ inches wide; several turns of the bandage were made as far as convenient from the focus of disease until distinct fulness of the veins resulted. Such constriction must never be painful, or even uncomfortable; on the contrary, pain in the diseased area tended to be relieved and a sense of increased well-being resulted. Pallor and coldness beyond the bandage must never be produced, and if such result even after mild tension this should be evidence that the case was not suitable for constriction.—Dr. B. G. Morison showed a man with a Fracture of the Spine of the Scapula with two skiagrams.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 13th, Dr. W. H. Cheetham being in the chair.—Mr. A. S. F. Grünbaum made some remarks on the principles underlying the use of the various bacterial vaccines, pointing out that toxin bacteria usually required antitoxic serum and endotoxin bacteria generally required vaccine for the efficient treatment of their respective infections. He recommended prophylactic inoculation of individuals of tuberculous diathesis when young and before the appearance of any symptoms.—Dr. Myer Coplans made some remarks on Points in Comparative Pathology. He showed specimens of tuberculosis produced experimentally in the guinea-pig, comparing the *centripetal* progress of the disease with those forms found naturally in the pig, while contrasting the *centrifugal* progress of the disease in lactating cows in which involvement of the pre-lumbar and supramammary glands nearly always preceded the onset of tuberculous mastitis, which, when present, should be regarded as a sufficient warrant for the animal's destruction. Sections illustrating the pathology of Johne's disease (enteritis of cattle) were shown and described. Smears of pus showing the cryptococcus of Revolta were shown and the differential diagnosis between glanders of the horse and epizootic lymphangitis was discussed. Macroscopic and microscopic specimens of the anthrax purple reaction as applied to animals naturally dead from the septicæmic form of the disease were exhibited and the pathological and legal aspects of the reaction were noted.—Dr. E. F. Trevelyan and Mr. R. G. Hann showed the Viscera from a case of Acute Phosphorus Poisoning.—Mr. H. Littlewood showed: 1. A specimen removed there was an easterly and westerly movement also. This was particularly striking in the case of the system over the South Indian Ocean, which moved with considerable regularity from the west coast of Australia to the east coast of South Africa and back again. It reached its extreme easterly position in February and its extreme westerly position as a rule in July. Observations have also been made which strongly support the view that the belt shifted its latitude and caused the action-centres to be displaced north and south of a mean position in certain years. If the belt shifted its latitude in accordance with this view the records of places in South Africa, such as Cape Town and Durban, ought to show a variation in the frequency of the winds from an easterly and westerly direction, if these places during some years were on the north side and during other years on the south side of the axis of the belt. Such variations in the direction of the wind have in fact been found to occur in both Cape Town and Durban. An examination of the rainfall records led to a similar result. The general inference was that in South Africa the belt occupied 19 years in passing from its extreme northerly position in 24° south latitude to its extreme southerly position in 34° south latitude and back again to its northerly position. In Australia a 19-year meteorological cycle has been recognised since 1846, and the years of drought were the very years when the belt, according to Colonel Rawson's hypothesis of the cyclical oscillation of the anticyclonic belts of the northern and southern hemispheres, would be at the extreme end of its oscillation. In these years the belt would be passing back again for the second time over districts which had already experienced dry anticyclonic weather. All sanitarians should be interested in the success of these prophecies, and British sanitarians in particular have a right to expect that such researches as Colonel Rawson described are facilitated by the State. On rainfall depend the main issues of life in most of the divisions of the earth, and our flag flies over many districts which can only be made into valuable national assets by attention to meteorological probabilities.

◆

The Objects of Examinations.

For want of a better method of coming to a decision as to the capabilities of intending practitioners of medicine examinations are employed but few would be so bold as to venture to assert that the examining system is perfect. Its faults are many, for in addition to those which may be termed intrinsic, as resulting from the very nature of an examination, there are also extrinsic faults which follow from the nature of the examiners and form no essential part of the examination itself. The object of an examination in medicine is to discover if the candidate is competent to carry on the work of a medical practitioner. Now, apart from an examination, an opinion on this point could be most easily formed by someone conversant with the whole life-history and training of the candidate, for it is by suitable and adequate training that the best results can be obtained. The examining bodies and the General Medical Council lay down schemes of study which the candidate must have completed by the time that he presents himself for examination, but every teacher and every examiner in medical subjects know what appalling ignorance may remain even after the student has passed through a prescribed course of study. This fact, for fact it is, is the basis of the need for examinations, and therefore an examination must be searching if the result of it is to be conclusive, yet the time devoted to the examination is so short that it is not easy for an examiner to decide at once on the merits of the average candidate. Some candidates are, of course, so obviously well trained and acquainted with the subjects of examinations that their passing is never for a moment a matter of doubt, and a few are obviously hopeless from the start; but the majority of candidates stand between these extremes and the difficulties of estimating the knowledge of each candidate are indeed great. The personal peculiarities of the examiner are likely to show themselves much more in the *vivâ voce* portion of the examination than in the written portion, but even in the examination papers there is much scope for infelicity in choosing questions. In pass examinations the questions cannot be too straightforward; they must be absolutely unambiguous and the terms and expressions employed should be those which are commonly employed in the subject, and they should not be the special creations of one special school or teacher. In the present issue of The Lancet we publish a letter in which complaint is made of one of the questions set at a recent examination of the University of London. We are not entering into the question whether the complaint is well founded or not, but if it be true that a large proportion of the candidates had never heard the expression on which the question was based it is clear that the expression was not in such common use as to justify its appearance in the paper of a pass examination. The main evils of examination papers are three. In the first place, the paper is liable to be too long unless the examiner takes the trouble to estimate, roughly at least, how long an adequate answer would take to write. It has been suggested that an examiner should be required to furnish with his set of questions typical written answers to his own questions. This would be perhaps rather hard on the examiner but it would certainly be very interesting to see the results. Secondly, a by no means infrequent fault is the employment of the rarer names for morbid conditions; it is better in an examination paper to speak of whitlow than of paronychia and of hip disease than of morbus coxæ. We have known instances in which each of these terms has caused much distress in the minds of many candidates. It may be urged that any well-educated candidate should be acquainted with these terms; that may be, but when the written question is such as this, "Describe the causes, symptoms, and treatment of morbus coxæ," the chance of obtaining a correct answer is made to depend not on the candidate's knowledge of the disease but on the chance of his knowledge of one of its rarer names, and that is a very different matter. It may be that the candidate possesses a good knowledge of disease of the hip, both theoretical and practical, but if it should happen that he has never heard or has forgotten "morbus coxæ," he is utterly unable to answer the question. Success in this case is made to depend not on a knowledge

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Nov. 13th. Mr. Edward Sergeant delivered his presidential address upon County Health Administration. After giving a short historical account of the evolution of the county medical officer of health, the President dealt with the various public health matters with which county councils are concerned. He described at some length the powers possessed by county councils with respect to the prevention of the pollution of rivers and pointed out that certain trade pollutions, such as those derived from dye, print, and bleach works, chemical works, tanneries, paper-making, woollen works, and silk works, were amenable to chemical and mechanical remedies which might be applied without interfering with manufacturing interests. He instanced the "Magma" process for recovering crude oil from the soap-suds used in dyeing operations and wool washing. In the indigo dyeing trade the spent vat liquors and wash waters after settlement gave a sludge containing so much indigo that it could be profitably re-used. In the manufacture of soap the spent lees were concentrated and distilled and the glycerine, which at one time was turned into the rivers, was now recovered. He considered that crude sewage should not be discharged into the open sea at low-water mark or into an estuary, more especially if the tidal currents were not sufficiently strong to remove or to dissipate the polluting matters without fear of their return. In the case of an estuary the sewage might be carried to sea very slowly and if discharged on the ebb tide might be carried only a short distance before it was driven back by the flood, and so oscillate backwards and forwards, causing a dangerous nuisance. Upon the vexed question of isolation hospital accommodation the President said that in his opinion a scarlet fever patient had a much better chance of recovery in an isolation hospital than in a cottage. He quite agreed that hospital isolation of scarlet fever patients had not quite answered the expectations that had been held out but he thought that no efficient sanitary authority could do without it. The non-removal policy had many attractions for parsimonious authorities, but he considered it wrong to endanger the health of neighbouring districts while engaged in the hopeless attempt to procure isolation in the ordinary dwellings of the working classes. In his remarks upon the administration of the Sale of Food and Drugs Acts he said that it was a grave reflection upon the Central Government that milk, the most important form of food so far as infants were concerned, should still continue to be subjected to frequent adulteration. The standard set up by the Board of Agriculture and Fisheries was, in his opinion, a good one, but its value was largely neutralised as it merely raised a presumption until the contrary was proved that the article was not genuine. He regretted that it was becoming increasingly difficult to obtain convictions in cases of alleged milk adulteration, and occasionally cases were dismissed by the magistrates even though no defence had been raised. In order to avoid such difficulties he considered that a fixed universal standard of genuineness should be adopted below which the sale of milk should be prohibited.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 20th, Dr. J. R. T. Conner, Vice-President, being in the chair.—Mr. Peter L. Daniel read a paper on the Treatment of Tuberculosis by Bier's Congestion and Hyperæmic Methods and by Injections of Iodoform Glycerine. He said that if they could mechanically obstruct the lymphatics and venules they were in possession of a valuable means of localising inflammatory processes and of thus protecting the whole body from invasion by bacteria and toxins, and "while limiting the process and protecting the body it permits nevertheless the whole body forces an opportunity to take part in the destruction of the germs." Iodoform glycerine acted in two ways: first, by mechanically obstructing the lymphatics; secondly, by inducing a hyperæmia—the reparative element of inflammation. By such obstruction to the lymph and venous flow a flooding of the diseased area with plasma took place, and however or wherever protective properties were manufactured in the living body they ultimately were conveyed by, and enabled to act through, the medium of the blood plasma; and as the arterial supply to the diseased area was quite unimpeded, this blood plasma charged with protective properties derived from the liver, spleen, marrow, and muscles permitted the whole body processes to be concentrated locally. By Bier's constricting bandage similar results were obtained in a more obvious manner, the essential point in this treatment being obstruction to the venous and lymphatic flow. Bier's methods consisted of (1) constriction by means of an elastic bandage; (2) suction by means of a suitable cupping glass; and (3) hot dry air. The constriction and suction produced lymphatic and venous congestion, but the hot air was said to induce an arterial hyperæmia. The constriction method, where it could be used, was the best method. The bandage used was made of elastic webbing, from 2 to 2½ inches wide; several turns of the bandage were made as far as convenient from the focus of disease until distinct fulness of the veins resulted. Such constriction must never be painful, or even uncomfortable; on the contrary, pain in the diseased area tended to be relieved and a sense of increased well-being resulted. Pallor and coldness beyond the bandage must never be produced, and if such result even after mild tension this should be evidence that the case was not suitable for constriction.—Dr. B. G. Morison showed a man with a Fracture of the Spine of the Scapula with two skiagrams.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 13th, Dr. W. H. Cheetham being in the chair.—Mr. A. S. F. Grünbaum made some remarks on the principles underlying the use of the various bacterial vaccines, pointing out that *toxin bacteria* usually required antitoxic serum and endotoxin bacteria generally required vaccine for the efficient treatment of their respective infections. He recommended prophylactic inoculation of individuals of tuberculous diathesis when young and before the appearance of any symptoms.—Dr. Myer Coplans made some remarks on Points in Comparative Pathology. He showed specimens of tuberculosis produced experimentally in the guinea-pig, comparing the *centripetal* progress of the disease with those forms found naturally in the pig, while contrasting the *centrifugal* progress of the disease in lactating cows in which involvement of the pre-lumbar and supramammary glands nearly always preceded the onset of tuberculous mastitis, which, when present, should be regarded as a sufficient warrant for the animal's destruction. Sections illustrating the pathology of Johne's disease (enteritis of cattle) were shown and described. Smears of pus showing the cryptococcus of Rivolta were shown and the differential diagnosis between glanders of the horse and epizootic lymphangitis was discussed. Macroscopic and microscopic specimens of the anthrax purple reaction as applied to animals naturally dead from the septicæmic form of the disease were exhibited and the pathological and legal aspects of the reaction were noted.—Dr. E. F. Trevelyan and Mr. R. G. Hann showed the Viscera from a case of Acute Phosphorus Poisoning.—Mr. H. Littlewood showed: 1. A specimen removed evils of examinations are removeable by care in the choice and the training of the examiners. While examinations persist as the method of eliminating the unsuitable the utmost care should be taken to make them as free from fault as may be.

Annotations.

"Ne quid nimis."

THE LONDON MILK-SUPPLY: A SERIOUS REVELATION.

At a meeting of the London County Council held on Nov. 17th the public health committee presented a report upon the steps which it had taken since July 1st ult. in accordance with the authority delegated to it by the Council under Part IV. of the London County Council (General Powers) Act, 1907, in dealing with the question of the milk-supply in connexion with tuberculosis. The report states that—

> A veterinary inspector has been appointed for the purposes of this Act, for the inspection of cows at farms outside London which supply milk within the county, and an arrangement has been made with the director of the Lister Institute for the examination of samples of milk taken under the Act. The first quarterly return of our action is now due, and for convenience we have extended the period under review to Oct. 10th, 1908. In the period in question we have had under consideration the method by which the Council's power can be most efficiently and economically exercised with a view to the protection of the London population from the risk of consumption of tuberculous milk. As the Council's powers have not been in operation long enough to allow of our reporting in detail upon the whole question, we think it well to submit the results of the examination of samples of milk and of veterinary inspection of the farms to the date already mentioned.
>
> During this time 204 samples of milk have been taken, 60 of which were of milk carried by the London and North-Western Railway Company, 48 by the Great Eastern Railway Company, 60 by the London and South-Western Railway Company, and 36 by the Great Western Rail Company. The examination of 92 of by the Lister Institute, with the resu 23·9) have proved to be tuberculous. has visited 20 of the farms from which the samples were taken and inspected the animals at 19 of them, it being proved that the remaining farm had not sent the sample of milk to London. As the result of clinical examinations nine cows were at once reported by the Council's veterinary inspector to have tuberculous udders. Another cow has subsequently proved to have a tuberculous udder, making ten cows in all proved to be suffering from this disease. The owner or manager at once undertook not to send to market in London more milk from these cows.
>
> The cost incurred by the Council in carrying out the provisions of Part IV. of the Act, for the period covered by this report, is estimated not to exceed £100.

It does not require much expert knowledge to realise the gravity of the state of affairs revealed by this research. The results are so striking that they claim the attention not only of the London County Council but of Parliament. That very nearly a quarter of the milk samples taken at random from the metropolitan supply should prove to be tuberculous affords a grave reflection upon the present provisions for its regulation. Year by year authoritative opinion tends more strongly to proclaim the frequency of alimentary infection in tuberculosis, and it is now the plain duty of the Government to pay attention to its expert sanitary advisers. It may seem useless to urge the discussion of a departmental measure at a time when such large issues as licensing and education are before Parliament but we make bold to consider that a "Pure Milk" Bill such as Mr. Burns was to have introduced in the summer session, but which has not yet seen the light, provided it be wisely drafted, will prove of no less vital importance to the country than larger Government measures which do so much more for their promoters' political reputation. Such a Bill will, we hope, be the speedy outcome of this disquieting report. In the meantime the fruits of the modest £100 which the public health committee of the London County Council has spent in the matter, should result in a special grant being made with which to carry on wider investigation. We trust that our readers will take every opportunity of making known the statements contained in this report. If medical men in family practice in London were to tell the mothers under their charge that there were only three chances to one in favour of obtaining for their children milk free from the active germs of a terrible disease, such a strong public opinion would be formed that Members of Parliament for metropolitan constituencies might find themselves being heckled with considerable vigour as to what they intended to do to prevent the children of the nation from being poisoned systematically.

DAMPNESS AND DISEASE.

The subject of dampness in its bearing on health does not seem to have received serious detailed study, or, if it has, very little light has been thrown on the exact way in which dampness acts as an etiological factor in disease. It is easy enough to suggest why dampness should lower the resistance of the human body to disease, but why in particular it appears to encourage such ailments as rheumatism, neuralgia, and diseases of the respiratory tract is not so apparent. The risks attending the sleeping in a damp bed can be understood, because when clothing is damp its function—viz., that of insulation—ceases and it no longer provides against the body losing its heat and so a chill is engendered, and a chill may bring almost any disease in its train, for a chill is nothing but a weakened resistance. Does the dampness of the air or of the soil act in a similar way? It is probable, for dampness permeates almost all materials and therefore life in a damp atmosphere means a body exposed to an undue loss of that animal heat which is necessary to keep the organism strong and vigorous. Conversely, a dry air, though intensely cold, is perfectly healthy so long as the individual protects or conserves his calorific status by wearing suitable non-conducting clothing. The analogue of the electric current is suggested. In dry countries the electric wires are frequently bare, requiring no insulation, whereas in damp places the leakage of current would be considerable if the wires were not well covered with insulating material. There are those who believe, further, that when dampness emanates from the soil it may carry with it disease-producing entities and, moreover, a moist environment is more congenial than is a dry one to the growth and development of micro-organisms. Indeed, when exposed long enough to very dry air some organisms may be destroyed. Dampness implies stagnation, a gloom in which evil things are lifted from the soil and kept suspended and brought within reach of the human organism. It is thus not difficult to generalise about dampness in its relation to disease but so far its influences have not been susceptible of really correct measurement. That it is associated with disease is evident from the instances of health being improved when the individual is removed from a damp to a dry locality.

NEALE *v.* THE BARTITSU LIGHT CURE INSTITUTE, LIMITED.

In this action, which was tried before Mr. Justice Grantham and a special jury, the plaintiff, Dr. A. E. Neale, sued the defendants for damages for breaches of an agreement, and the defendants counter-claimed for damages, alleging negligence and incompetence on the part of the plaintiff. The plaintiff was awarded by the jury £600 damages on his claim and obtained a verdict as defendant to the counterclaim, judgment being given in his favour and a stay of execution refused. The agreement in respect of which the damages were given secured the services of the plaintiff as medical superintendent of the institute upon terms safe-guarding him against loss of dignity and against any allegation of ethical misconduct. He was to have entire control of the treatment, he was produce punched-out sores. The note was also discussed by the President, Dr. F. W. B. Young, Dr. E. T. Davies, Dr. S. M. Whittaker, and Dr. J. Lloyd Roberts.—Mr. G. P. Newbolt read a paper on Suprapubic Prostatectomy. He advised operation in the following conditions: (1) complete retention and catheter life in otherwise healthy men; (2) frequent micturition rendering life unbearable and coming on at an early age; (3) profuse hæmorrhage from the prostate and recurring at frequent intervals; and (4) occasional retention with difficulty in the passage of, or inability to pass, a catheter. He did not advocate the operation in malignant disease. He considered that any after-trouble in the way of stricture was due to removal of the membranous urethra.—Mr. F. T. Paul considered that the operation was very remarkable in the results derived from it. In performing the operation he made as small a wound in the bladder as he could work with. He commenced enucleation within the neck of the bladder. If hæmorrhage occurred after the operation he removed the tube when, as a rule, the bleeding would stop. He never operated in cases where he considered the enlargement to be malignant.—Mr. W. Thelwall Thomas believed that the mortality would in the future be lessened by operating earlier in the condition. He always made a curved transverse incision and employed air distension of the bladder. Recently he had employed perineal drainage, as suggested by Lynn Thomas, and was very pleased with this improved method.—The paper was also discussed by the President, Dr. Davies, Mr. D. Douglas-Crawford, and Mr. R. A. Bickersteth.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Nov. 13th. Mr. Edward Sergeant delivered his presidential address upon County Health Administration. After giving a short historical account of the evolution of the county medical officer of health, the President dealt with the various public health matters with which county councils are concerned. He described at some length the powers possessed by county councils with respect to the prevention of the pollution of rivers and pointed out that certain trade pollutions, such as those derived from dye, print, and bleach works, chemical works, tanneries, paper-making, woollen works, and silk works, were amenable to chemical and mechanical remedies which might be applied without interfering with manufacturing interests. He instanced the "Magma" process for recovering crude oil from the soap-suds used in dyeing operations and wool washing. In the indigo dyeing trade the spent vat liquors and wash waters after settlement gave a sludge containing so much indigo that it could be profitably re-used. In the manufacture of soap the spent lees were concentrated and distilled and the glycerine, which at one time was turned into the rivers, was now recovered. He considered that crude sewage should not be discharged into the open sea at low-water mark or into an estuary, more especially if the tidal currents were not sufficiently strong to remove or to dissipate the polluting matters without fear of their return. In the case of an estuary the sewage might be carried to sea very slowly and if discharged on the ebb tide might be carried only a short distance before it was driven back by the flood, and so oscillate backwards and forwards, causing a dangerous nuisance. Upon the vexed question of isolation hospital accommodation the President said that in his opinion a scarlet fever patient had a much better chance of recovery in an isolation hospital than in a cottage. He quite agreed that hospital isolation of scarlet fever patients had not quite answered the expectations that had been held out but he thought that no efficient sanitary authority could do without it. The non-removal policy had many attractions for parsimonious authorities, but he considered it wrong to endanger the health of neighbouring districts while engaged in the hopeless attempt to procure isolation in the ordinary dwellings of the working classes. In his remarks upon the administration of the Sale of Food and Drugs Acts he said that it was a grave reflection upon the Central Government that milk, the most important form of food so far as infants were concerned, should still continue to be subjected to frequent adulteration. The standard set up by the Board of Agriculture and Fisheries was, in his opinion, a good one, but its value was largely neutralised as it merely raised a presumption until the contrary was proved that the article was not genuine. He regretted that it was becoming increasingly difficult to obtain convictions in cases of alleged milk adulteration, and occasionally cases were dismissed by the magistrates even though no defence had been raised. In order to avoid such difficulties he considered that a fixed universal standard of genuineness should be adopted below which the sale of milk should be prohibited.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 20th, Dr. J. R. T. Conner, Vice-President, being in the chair.—Mr. Peter L. Daniel read a paper on the Treatment of Tuberculosis by Bier's Congestion and Hyperæmic Methods and by Injections of Iodoform Glycerine. He said that if they could mechanically obstruct the lymphatics and venules they were in possession of a valuable means of localising inflammatory processes and of thus protecting the whole body from invasion by bacteria and toxins, and "while limiting the process and protecting the body it permits nevertheless the whole body forces an opportunity to take part in the destruction of the germs." Iodoform glycerine acted in two ways: first, by mechanically obstructing the lymphatics; secondly, by inducing a hyperæmia—the reparative element of inflammation. By such obstruction to the lymph and venous flow a flooding of the diseased area with plasma took place, and however or wherever protective properties were manufactured in the living body they ultimately were conveyed by, and enabled to act through, the medium of the blood plasma; and as the arterial supply to the diseased area was quite unimpeded, this blood plasma charged with protective properties derived from the liver, spleen, marrow, and muscles permitted the whole body processes to be concentrated locally. By Bier's constricting bandage similar results were obtained in a more obvious manner, the essential point in this treatment being obstruction to the venous and lymphatic flow. Bier's methods consisted of (1) constriction by means of an elastic bandage; (2) suction by means of a suitable cupping glass; and (3) hot dry air. The constriction and suction produced lymphatic and venous congestion, but the hot air was said to induce an arterial hyperæmia. The constriction method, where it could be used, was the best method. The bandage used was made of elastic webbing, from 2 to 2½ inches wide; several turns of the bandage were made as far as convenient from the focus of disease until distinct fulness of the veins resulted. Such constriction must never be painful, or even uncomfortable; on the contrary, pain in the diseased area tended to be relieved and a sense of increased well-being resulted. Pallor and coldness beyond the bandage must never be produced, and if such result even after mild tension this should be evidence that the case was not suitable for constriction.—Dr. B. G. Morison showed a man with a Fracture of the Spine of the Scapula with two skiagrams.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 13th, Dr. W. H. Cheetham being in the chair.—Mr. A. S. F. Grünbaum made some remarks on the principles underlying the use of the various bacterial vaccines, pointing out that toxin bacteria usually required antitoxic serum and endotoxin bacteria generally required vaccine for the efficient treatment of their respective infections. He recommended prophylactic inoculation of individuals of tuberculous diathesis when young and before the appearance of any symptoms.—Dr. Myer Coplans made some remarks on Points in Comparative Pathology. He showed specimens of tuberculosis produced experimentally in the guinea-pig, comparing the *centripetal* progress of the disease with those forms found naturally in the pig, while contrasting the *centrifugal* progress of the disease in lactating cows in which involvement of the pre-lumbar and supramammary glands nearly always preceded the onset of tuberculous mastitis, which, when present, should be regarded as a sufficient warrant for the animal's destruction. Sections illustrating the pathology of Johne's disease (enteritis of cattle) were shown and described. Smears of pus showing the cryptococcus of Revolta were shown and the differential diagnosis between glanders of the horse and epizootic lymphangitis was discussed. Macroscopic and microscopic specimens of the anthrax purple reaction as applied to animals naturally dead from the septicæmic form of the disease were exhibited and the pathological and legal aspects of the reaction were noted. —Dr. E. F. Trevelyan and Mr. R. G. Hann showed the Viscera from a case of Acute Phosphorus Poisoning.—Mr. H. Littlewood showed: 1. A specimen removed good repute, but they are an object-lesson to us timid moderns. For, exclaims Sir Walter Besant, they drank, according to their accounts, "two kilderkins, or 36 gallons, of beer every week! 144 quarts a week! 21 quarts a day! It means nearly three quarts a head. This seems impossible. There must have been some external assistance. But it is not really impossible." Small beer was the national beverage and took the place of tea, then 60*s.* a pound, and of spirits, of which the family seem only once to have bought a bottle. The family drank much home-made wine besides and on occasion bought a cask of wine containing 42 gallons (a tierce). Yet they kept a fairly lavish table at the same time though their consumption of milk and bread was minute. It cannot, therefore, be maintained that they were an abnormal instance of merely old-time beer-drinking. It would be interesting, however, to know how long "Mr. Arthur" lived, for instance, and from what he died. Old necropsies yield curious information as to the state of the liver. The great Dr. Samuel Johnson is known to have numbered cirrhosis of the liver among his other grave ailments, such as scrofula, an epileptic tendency, gravel, and dropsy.

THE SERUM TREATMENT OF EPIDEMIC CEREBRO-SPINAL MENINGITIS.

EPIDEMIC cerebro-spinal meningitis is attended by such a high mortality that any treatment which gives promising results deserves a trial. As was shown at the discussion at the last meeting of the British Medical Association there is now considerable evidence[1] that a serum prepared from the horse in a similar way to that for the treatment of diphtheria exercises a markedly beneficial effect. Such a serum was first produced in 1906 by two German workers, Kölle and Wassermann, by inoculating horses with both dead and living cultures of the meningococcus. Then Kromer treated 17 cases of cerebro-spinal meningitis by injecting hypodermically from 20 to 30 cubic centimetres of serum and repeating the injection on the second and third days. In 11 cases the serum was on the second occasion injected into the spinal canal. Only five of the patients died. In 1907 Schone treated a series of 30 cases with a death-rate of 28 per cent. against 53 per cent. in other cases. Of many serums manufactured the best appears to be one prepared by Dr. Simon Flexner at the Rockefeller Institution, New York. In monkeys he produced meningitis by injection of cultures of meningococci through a lumbar puncture. The animals for the most part rapidly died with lesions resembling those of cerebro-spinal meningitis in man, but serum treatment proved remarkably successful. In the *Edinburgh Medical Journal* for October Dr. Claude B. Ker has reported most favourably on the value of Flexner's serum in the recent epidemic of cerebro-spinal meningitis in that city. The usual dose given to children was 30 cubic centimetres, which was injected into the spinal canal after removing as much cerebro-spinal fluid as would flow on lumbar puncture. The dose was usually administered daily for three or four days. In favourable cases there was usually a lower temperature on the next day and there were frequently less delirium and some return of consciousness. The cyanosed face assumed a more healthy colour and the rigidity of the neck diminished. Occasionally the disease terminated in crisis—a point on which Dr. Flexner lays great stress, as the natural tendency is to termination by lysis. The mortality rate was 42·3 per cent., against 80·5 per cent. for the cases otherwise treated. Other writers have published even better results from this serum. Dr. A. Gardner Robb in the recent Belfast epidemic had a mortality of only 30 per cent. Observations made in the City Hospital Laboratory, Edinburgh, by Dr. T. Lauder Thomson show that the injections had a remarkable action on the cerebro-spinal fluid. Before the injections the fluid was sometimes very turbid and contained many extra-cellular and intra-cellular organisms. The extra-cellular ones disappeared early and the staining properties of the diplococci altered, and in one or two days they appeared to disintegrate and it was difficult to grow cultures from them. Dr. Ker has also tried several other serums but he finds that Flexner's gives the best results and that the serum prepared by Kölle and Wassermann comes next. In the *Boston Medical and Surgical Journal* of Oct. 22nd and 29th Dr. F. T. Fulton has reported good results from Flexner's serum. In nearly all the cases in which there was reason to hope for benefit an improvement was coincident with administration of the serum and recovery gradually took place. The total mortality was 37 per cent. and on eliminating moribund and chronic cases the mortality was only 20 per cent. The effect on the cerebro-spinal fluid was even more striking. In all but one case the purulent or turbid fluid became clear and the meningococci disappeared.

LAMP EXPLOSIONS.

Mr. William Thomson, F.I.C., F.R.S. Edin., who has for several years conducted for the Manchester and Salford Sanitary Association an investigation into the causes of lamp explosions, has brought it up to date in a report just presented to the association. The report confirms the conclusions of THE LANCET Commission on Dangerous Paraffin Lamps, published in THE LANCET of Jan. 4th, 1896. It runs as follows:—

> Since my last report of the 31st March, 1906, the chief constables of Manchester and Salford have passed to me through you for investigation the remains of six lamps which were alleged to have exploded during the year 1906, and of five lamps during the year 1907, the descriptions of which are given in the table annexed hereto. You will see from this table that 10 lamps out of [illegible] seven of which are without a side tube [illegible] employed in the lamps which exploded [illegible] out of the 11, two having a flash-point of 85° Fah., one of 83° Fah., and the last 91° Fah. This shows that the oils of the Russian type are more [illegible] than either the low flash-point oils of the [illegible] flash-point oils of the Scotch type. It may [illegible] number of alleged explosions of oil-lamps which have occurred in Manchester and Salford during the last 12 years (1896–1907) as follows:—

	Explosions.		Explosions.
In 1896	15	In 1902	4
,, 1897	12	,, 1903	4
,, 1898	18	,, 1904	4
,, 1899	17	,, 1905	3
,, 1900	9	,, 1906	6
,, 1901	8	,, 1907	5

> In 1908 up to the present time (Nov. 17th) none.
>
> On comparing this with my previous reports it will be observed that a marked diminution has taken place in the number of alleged lamp explosions since the association first entered upon this investigation, indicating great improvement in the construction of lamps. The number of explosions would, I think, be still further reduced if the length of the wick tube were increased.

> *Details of the Lamp Explosions in 1906 and 1907.*
>
> *March 27th, 1906 (Manchester).*—Supposed to have originated by the bursting of a paraffin lamp which had been left burning. The bedding was on fire. Damage about 30*s.* Queen Anne burner with side tube. Flash-point of oil, 91° F.
>
> *April 4th (Manchester).*—Lamp exploded whilst standing on the kitchen table, setting fire to the table and dresser. Duplex burner. No oil sent.
>
> *April 7th (Manchester).*—The tenant of the house was about to remove the table in the kitchen when the lamp exploded and set fire to a table cloth and apron, also doing damage to the kitchen floor. Queen Anne burner without side tube. Flash-point, 85° F.
>
> *June 10th (Manchester).*—The tenant was moving a paraffin lamp in the bedroom when it exploded in her hand. The flames were put out before any damage was done. Queen Anne burner with side tube. No oil.
>
> *Sept. 2nd (Salford).*—Lamp exploded whilst standing on the table. Set the curtains on fire. Damage 2*s.* Queen Anne burner without side tube. No oil
>
> *Nov. 6th (Manchester).*—Paraffin lamp exploded, setting fire to some clothing in the kitchen. Damage about 8*s.* Queen Anne burner without side tube. No oil.
>
> *March 28th, 1907 (Manchester).*—Lamp exploded whilst standing on the table. The curtains were set on fire. Queen Anne burner without side tube. Flash-point, 83° F.
>
> *April 2nd (Manchester).*—Lamp exploded whilst hanging on the back window frame. Set fire to the furniture. Damage £17. Queen Anne burner without side tube. No oil sent.

---

[1] THE LANCET, August 15th, 1908, p. 472.

bring the present edition into complete line with the elegances and refinements of modern pharmaceutical attainments. Needless to say, the record of this pharmaceutical progress faithfully described in the pages has necessitated the practical rewriting of the work. The following figures serve to show the growth of the "Companion" since it was first introduced. In 1864 the "Companion" contained 220 pages; in 1874, 458 pages; in 1886, 562 pages; in 1890, 660 pages; in 1894, 733 pages; in 1899, 882 pages; and the present edition no less than 1459 pages. While, therefore, there was a steady addition of about 100 pages in the succeeding editions up to 1899 the number of pages added to that edition and now contained in the present edition is nearly 600. It may be said, therefore, that very nearly half of the text in the new edition has been allocated to new pharmacy, to the advances, that is to say, which have been made in the testing and chemical and physiological standardisation of drugs and chemicals used in medicine, in the elaboration of synthetic remedies, in the presentation of old medicaments in new and more effectual form, and so forth. Further, the new editions of the foreign pharmacopœias, including even the Japanese Pharmacopœia, have received consideration. The publication of the "Companion" was in fact delayed owing to the author's desire to include the more important tests of the French Codex which has only recently been published. In spite of the attention which has thus been given to points on which the modern practitioner and pharmacist will welcome an authority, the "Companion" preserves its old "get-up" and the general arrangement remains the same as before. The special feature which, for example, has rendered the book so convenient as a work of reference in the past is the prominent distinction in type which is drawn between the "official" and "not official" preparations. This plan, to mention one decided advantage, places before the prescriber a complete list of "official" and "not official" preparations given under each substance immediately following the dose, so that he can readily and without further reference ascertain the various forms in which any medicament may be given.

As to the instances which may be quoted of the important additions made since the seventeenth edition was issued a few will suffice to prove the care which has been taken to make the present edition a faithful record of modern advances. We may refer to the monographs on aconite, belladonna, cinchona, cocaine and its "not official" preparations alypin, novocaine, stovaine, and tropacocaine, and on ergot, the recent researches on ergotoxine which is now regarded to be the most important active principle being described. Further are to be found monographs on similar developments in regard to the pharmacology of nux vomica, ipecacuanha, opium, jaborandi, and pilocarpine salts, an article on quinine sulphate in which the new French pharmaceutical tests are introduced, a useful reference to the new organic arsenic compounds, including atoxyl, and also to mercury compounds. A good deal of fresh work has been involved in the re-writing of the section on prescribing notes, examples of which appear under ergot, iodoform, and tinctures. Finally, it is not surprising to find that due attention has been given to the subject of solubilities, since the importance of it was first recognised by the late Peter Squire, figures for the solubility of chemical substances having been introduced by him in the earliest editions of the "Companion," which were subsequently included in the British Pharmacopœia. The sections on "tests" present advantages to the practitioner, for in them the requirements of the Pharmacopœia are interpreted into figures of absolute percentages, so that he need not be concerned what a definite weight of a substance should require in the way of a definite volume of a certain standard solution, or what definite weight of precipitate a definite weight of a certain substance should yield when treated with certain reagents.

The chapter on "Medicinal Properties" has been revised by Dr. Taylor Grant; that on "Descriptive Notes" has been written by Mr. E. M. Holmes who has also assisted in the revision of the organic materia medica; and finally the chapter on Therapeutic Agents of Microbial Origin (therapeutic sera, tuberculin, opsonins, and vaccines) is by Professor R. Tanner Hewlett.

The "Companion" is a classic, but it is a standard also, and the author, together with his laboratory staff and collaborators, may be congratulated heartily on having completed a work which, because of its thorough and authoritative character, is sure to receive the appreciation of physician, chemist, and pharmacist alike.

Surra in the Federated Malay States. By HENRY FRASER, M.D. Aberd., Director of the Institute for Medical Research; and S. L. SYMONDS, V.S. Melb., Government Veterinary Surgeon. With a note on the Distribution of Certain Species of Biting Flies in the Federated Malay States by H. C. PRATT, Government Entomologist. Numerous illustrations and diagrams. Singapore: Kelly and Walsh, Limited. 1908. Pp. 38. Price 3*s.* 6*d.* net.

THIS short treatise on surra is the ninth of a series of studies issued by the Institute for Medical Research, Federated Malay States. The work at present before us is the result of the coöperative researches of the medical, veterinary, and entomological experts, the result of such combined work being eminently satisfactory. The treatise embodies a short description of the exhaustive and far-reaching experiments which have been carried out in the Malay States for the purpose of making clear the causation, means of spread, and possibilities of prevention and treatment of this fatal animal scourge. The observations—made, as they are, independently of the researches which have been, and are being, carried out in India (where the disease was discovered by Evans, after whom the causal trypanosome is named)—are valuable as confirming and extending our knowledge of the disease.

The experiments recorded have been carried out intelligently and clearly demonstrate that the causal organism is the trypanosoma Evansi and that it is indistinguishable in morphology and pathology in horses, cattle, and dogs, the only differences being in regard to virulence. It is equally clear that the biting flies which are responsible for its transmission from animal to animal belong to the genus Tabanus, the existence of which flies is dependent on the presence of jungle; hence there is a much lower percentage of cases in the towns. A most important problem still, however, remains unsolved, and that is as to whether the trypanosome passes one part of its life-cycle in the fly, and experiments conducted to elucidate this proved inconclusive. It was, however, shown that trypanosomes are not to be found in the intestinal tract of the infected fly after 24 hours.

Observations have been made on naturally infected horses, oxen, and dogs, and on cases which have been infected experimentally, the subjects for these latter being chosen to demonstrate the course of the disease in animals of various ages and condition. Animals in good condition and others in poor condition have been infected and the result in all cases has been the same provided the quantity of material used was similar. The most certain method of transmission was subcutaneous inoculation with infected fresh blood, but it has also been shown that a mere scratch with an infected needle is sufficient to set up the disease. It has been found a difficult and often disappointing task to effect the transmission of the trypanosome by the natural means—namely, the Tabanus. The course of the disease and the ailments met with in general practice. The proceedings terminated with the toast of "The Society of Apothecaries," proposed by the Lord Mayor, to which the Master replied in suitable terms. In spite of the somewhat crowded state of the charming old hall the occasion was a most enjoyable one and a good programme of music provided further for the entertainment of the guests.

THE PRODUCTION OF ALKALI BY THE BACILLUS PESTIS.[1]

THE latest addition to the very valuable series of Memoirs by Officers of the Medical and Sanitary Departments of the Government of India is concerned with the property possessed by the bacillus pestis of producing alkali when growing in broth. The author, Lieutenant-Colonel W. B. Bannerman, I.M.S., shows that the arrest of growth which occurs in plague cultures after a month or six weeks is not due to exhaustion of the medium, still less to the production of acid, but to this constant development of alkali by the bacillus. The amount of alkali produced is equivalent to 1·5 to 2·5 per cent. of normal sodium hydroxide, and this quantity which is reached in from six weeks to two months causes arrest of growth but not death of the bacillus. Neutralisation of the alkali is followed by fresh growth. An interesting sidelight on the unexpected connexion between science and religion is afforded by the fact that as artificial peptone may not be employed in the manufacture of the cultivating medium lest the religious prejudices of certain sections of the Indian community should be offended, it has been necessary to devise a method of preparing broth by digestion of meat in dilute hydrochloric acid which avoids this difficulty. The broth as made according to this method, devised by Dr. F. Maitland Gibson, appears to be very suitable for the growth of bacillus pestis.

A NEW MICRO-ORGANISM CAUSING DISEASE IN THE CAT.

FOR some years past an epidemic has occurred during the winter among the cats in the domain of La Gastine (Eure). During February of this year the body of a cat which had died from this disease was sent to the laboratory of M. Danysz, owing to the fact that the proprietor of the domain had employed the Danysz cocco-bacillus for the destruction of rats, and he supposed that the epidemic among the cats might be derived from this source. The disease was investigated by M. M. Z. Skrzynski, who found that it was due to a hitherto undescribed organism belonging to the group of the colon bacillus. It proved to be entirely different from the Danysz bacillus, since it was pathogenic for the cat but practically harmless to rats and mice. His results are described in detail in the August number of the *Annales de l'Institut Pasteur*, and they constitute an interesting addition to the pathogenic members of the colon group of organisms. The organisms have the form of rods with rounded ends but also occur in ovoid forms. They never form filaments. They can be distinguished from typical colon bacilli by the fact that they are immobile in all media and under all conditions of culture, by the appearance of the cultures on agar, and by the fact that they do not cause fermentation of the cane-sugar in a medium containing agar and sugar. The organism is readily stained by the ordinary aniline stains but does not retain the stain in Gram's method. It does not form spores or possess a capsule. It grows well on all ordinary culture media between the temperature limits of 12° and 46° C., with an optimum at 37° C. The cultures on certain media acquire a fœtid odour like that of bacillus coli after two or three days' growth. The organism grows with great rapidity in bouillon which becomes turbid two or three hours after inoculation. It does not liquefy gelatin. On agar the culture becomes apparent after from four to six hours. The colonies are shiny and moist, with regular margins slightly raised in the form of a cone, with a central white point. In a culture of several days' growth long crystals become visible, evidently due to the precipitation of phosphates. The investigation of its bio-chemical properties shows that it has no appreciable action on protein substances but that it produces indol. It also produces reducing substances but its power in this direction is from 10 to 12 times less than that of the bacillus coli. Experiments showed that this organism produced fatal disease in cats but that immunity could be produced either by inoculation with attenuated cultures or by preparing a specific serum.

JUSTICES AND DIRTY MILK.

ALTHOUGH two samples of milk taken at Eastbourne recently were each found by the analyst to contain a trace of pus and blood, the prosecuting authority met with failure when the cases came before the justices. The milk was genuine and free from preservatives, but, in view of the discoveries made, it was thought necessary in the interests of the public health that proceedings should be taken. In the case that was taken first objection was raised to the certificate of the analyst on the ground (1) that it was too vague; and (2) that the analyst did not certify whether any change had taken place in the milk. The justices upheld the latter objection and the case was dismissed, the presiding magistrate remarking that he thought "trace" was also too vague. In view of this result the prosecuting solicitor did not proceed with the second case. The decision of the justices is rather surprising, and not the less so seeing that it is said that immediately after hearing the case referred to they fined a dairyman for selling weak milk. Weak milk would be far preferable to milk containing pus and blood, no matter how infinitesimal the quantity might be. However, it is to be hoped that the sanitary authority concerned will cause a thorough inspection to be made of the two farms which supplied the milk from which these samples were taken, and, so far as the present laws will permit, will call upon the farmers to remedy any evils that may be found to exist.

DANGEROUS PERFORMANCES.

WE have had occasion from time to time to record serious accidents to performers of foolhardy feats at public shows, accidents which in more than one instance have had a fatal ending. In August last, for instance, we called attention to the fate of an unfortunate lion-tamer's assistant who was mauled to death at a Gloucester theatre by one of his dangerous charges. Accidents of a similar nature have happened in the past to high-wire walkers, chariot drivers, acrobats, "parachutists," and others, who daily take their lives in their hands to gain the means of living. The most unfortunate of these episodes which is within our recollection happened at a London music hall on the night of Nov. 23rd in the course of a "fancy shooting turn" by a performer described as "Clementine—Lady Expert, Queen of Firearms." One of her feats was based on the well-known William Tell act, in which the performer discharges a rifle at a ball poised above an assistant's head. In most of such performances, we understand, the end is attained by some sort bring the present edition into complete line with the elegances and refinements of modern pharmaceutical attainments. Needless to say, the record of this pharmaceutical progress faithfully described in the pages has necessitated the practical rewriting of the work. The following figures serve to show the growth of the "Companion" since it was first introduced. In 1864 the "Companion" contained 220 pages; in 1874, 458 pages; in 1886, 562 pages; in 1890, 660 pages; in 1894, 733 pages; in 1899, 882 pages; and the present edition no less than 1459 pages. While, therefore, there was a steady addition of about 100 pages in the succeeding editions up to 1899 the number of pages added to that edition and now contained in the present edition is nearly 600. It may be said, therefore, that very nearly half of the text in the new edition has been allocated to new pharmacy, to the advances, that is to say, which have been made in the testing and chemical and physiological standardisation of drugs and chemicals used in medicine, in the elaboration of synthetic remedies, in the presentation of old medicaments in new and more effectual form, and so forth. Further, the new editions of the foreign pharmacopœias, including even the Japanese Pharmacopœia, have received consideration. The publication of the "Companion" was in fact delayed owing to the author's desire to include the more important tests of the French Codex which has only recently been published. In spite of the attention which has thus been given to points on which the modern practitioner and pharmacist will welcome an authority, the "Companion" preserves its old "get-up" and the general arrangement remains the same as before. The special feature which, for example, has rendered the book so convenient as a work of reference in the past is the prominent distinction in type which is drawn between the "official" and "not official" preparations. This plan, to mention one decided advantage, places before the prescriber a complete list of "official" and "not official" preparations given under each substance immediately following the dose, so that he can readily and without further reference ascertain the various forms in which any medicament may be given.

---

[1] [illegible] Pestis. By Lieutenant- [illegible] No. 33 (New Series) [illegible] and Sanitary Departments of the Government [illegible] 1908. 12 pp. Price 5 annas (6*d*.).

As to the instances which may be quoted of the important additions made since the seventeenth edition was issued a few will suffice to prove the care which has been taken to make the present edition a faithful record of modern advances. We may refer to the monographs on aconite, belladonna, cinchona, cocaine and its "not official" preparations alypin, novocaine, stovaine, and tropacocaine, and on ergot, the recent researches on ergotoxine which is now regarded to be the most important active principle being described. Further are to be found monographs on similar developments in regard to the pharmacology of nux vomica, ipecacuanha, opium, jaborandi, and pilocarpine salts, an article on quinine sulphate in which the new French pharmaceutical tests are introduced, a useful reference to the new organic arsenic compounds, including atoxyl, and also to mercury compounds. A good deal of fresh work has been involved in the re-writing of the section on prescribing notes, examples of which appear under ergot, iodoform, and tinctures. Finally, it is not surprising to find that due attention has been given to the subject of solubilities, since the importance of it was first recognised by the late Peter Squire, figures for the solubility of chemical substances having been introduced by him in the earliest editions of the "Companion," which were subsequently included in the British Pharmacopœia. The sections on "tests" present advantages to the practitioner, for in them the requirements of the Pharmacopœia are interpreted into figures of absolute percentages, so that he need not be concerned what a definite weight of a substance should require in the way of a definite volume of a certain standard solution, or what definite weight of precipitate a definite weight of a certain substance should yield when treated with certain reagents.

The chapter on "Medicinal Properties" has been revised by Dr. Taylor Grant; that on "Descriptive Notes" has been written by Mr. E. M. Holmes who has also assisted in the revision of the organic materia medica; and finally the chapter on Therapeutic Agents of Microbial Origin (therapeutic sera, tuberculin, opsonins, and vaccines) is by Professor R. Tanner Hewlett.

The "Companion" is a classic, but it is a standard also, and the author, together with his laboratory staff and collaborators, may be congratulated heartily on having completed a work which, because of its thorough and authoritative character, is sure to receive the appreciation of physician, chemist, and pharmacist alike.

Surra in the Federated Malay States. By HENRY FRASER, M.D. Aberd., Director of the Institute for Medical Research; and S. L. SYMONDS, V.S. Melb., Government Veterinary Surgeon. With a note on the Distribution of Certain Species of Biting Flies in the Federated Malay States by H. C. PRATT, Government Entomologist. Numerous illustrations and diagrams. Singapore: Kelly and Walsh, Limited. 1908. Pp. 38. Price 3*s.* 6*d.* net.

THIS short treatise on surra is the ninth of a series of studies issued by the Institute for Medical Research, Federated Malay States. The work at present before us is the result of the coöperative researches of the medical, veterinary, and entomological experts, the result of such combined work being eminently satisfactory. The treatise embodies a short description of the exhaustive and far-reaching experiments which have been carried out in the Malay States for the purpose of making clear the causation, means of spread, and possibilities of prevention and treatment of this fatal animal scourge. The observations—made, as they are, independently of the researches which have been, and are being, carried out in India (where the disease was discovered by Evans, after whom the causal trypanosome is named)—are valuable as confirming and extending our knowledge of the disease.

The experiments recorded have been carried out intelligently and clearly demonstrate that the causal organism is the trypanosoma Evansi and that it is indistinguishable in morphology and pathology in horses, cattle, and dogs, the only differences being in regard to virulence. It is equally clear that the biting flies which are responsible for its transmission from animal to animal belong to the genus Tabanus, the existence of which flies is dependent on the presence of jungle; hence there is a much lower percentage of cases in the towns. A most important problem still, however, remains unsolved, and that is as to whether the trypanosome passes one part of its life-cycle in the fly, and experiments conducted to elucidate this proved inconclusive. It was, however, shown that trypanosomes are not to be found in the intestinal tract of the infected fly after 24 hours.

Observations have been made on naturally infected horses, oxen, and dogs, and on cases which have been infected experimentally, the subjects for these latter being chosen to demonstrate the course of the disease in animals of various ages and condition. Animals in good condition and others in poor condition have been infected and the result in all cases has been the same provided the quantity of material used was similar. The most certain method of transmission was subcutaneous inoculation with infected fresh blood, but it has also been shown that a mere scratch with an infected needle is sufficient to set up the disease. It has been found a difficult and often disappointing task to effect the transmission of the trypanosome by the natural means—namely, the Tabanus. The course of the disease and the under the Royal Automobile Club observation three cars were picked out of their stock by the club officials. They were then entirely dismantled at Brooklands; the parts were mixed up, some taken away, and fresh ones obtained from the store; and then the three cars were reassembled and driven without any mechanical trouble for over 500 miles. This company also show their new 30-h.p. four-cylinder car.

A very novel and powerful two-seater is the 12-h.p. Sizaire-Naudin, which, fitted with a wind screen and hood, makes a fast and reliable car for professional use. The front axle is quite original; it is really the front member of the frame, and the steering-head spindles slide through the ends of this forging, and thus each front wheel is free to rise or to fall independently of the other, and a front inverted semi-elliptic spring supports the weight of the chassis. The drive is by a cardan shaft to a live axle and a tube hinged to a cross member of the chassis and fixed to the axle casing takes the torque. The change-speed mechanism is in the axle casing.

The makers of the popular little red "taxies," Messrs. Renault, have a small two-cylinder, 7-9-h.p. car which, if fitted with a different body to the one shown, struck me would make an ideal two-seater, with a Cape-cart hood and a front mica wind screen. It looked just the handy sort of car for the medical man who drives himself.

Messrs. Bentall, who have for years made parts of cars, are now turning out entire cars at their factory near Maldon in Essex. Their exhibit comprised samples of their 11-h.p. two-cylinder and 16-h.p. four-cylinder cars. Unlike in the majority of this year's cars, they have low-tension magneto, which the makers think less complicated than the high-tension. The clutch is of the internal cone type, faced with fibre and runs in oil, and is said to be very soft in action. The rest of the car follows the modern up-to-date lines and seems in every way well built and designed.

The Singer Company of Coventry have a neat little four-cylinder; the engines are 80 by 90 and give 12-14-h.p. Ignition is by coil and accumulator, as well as high-tension magneto. Cooling is by thermo-syphon, the usual water-pump being conspicuous by its absence. The gear-box gives four forward speeds, the direct being on the third, and there certainly seems an advantage in having four instead of three speeds; often, and especially in these small four-cylinders, one comes to a hill which is just too much for the top speed; with only three speeds, the second is too great a drop. With four the third is just what is often needed, and two more gear wheels is not a great addition for this advantage.

The gallery seemed very crowded, especially that part where the tyre dealers are all herded together; no end of people seemed interested in the tyre exhibits, and I should say that their makers must have booked many orders, even though some of the multitude around may have been "dead-heads." Messrs. Harvey, Frost, and Co. showed their "Baby" Car and "Garrage" vulcanisers, which certainly seemed excellent aids to the preservation of the life of a tyre. It is so true with tyres that "a stitch in time saves nine"; a small cut in a cover filled in and vulcanised may prolong the existence of that cover for many a month; ordinary stopping may, of course, stay in, but a proper vulcanised repair is much safer.

Messrs. Rotherham of Coventry had on view a large number of lubricators, oil cups, and grease feeders, components that even careful drivers who do screw up these parts may occasionally lose and which can be more easily matched by these makers than elsewhere. They also make pressure taps, needle valves for carburettors, nipples and unions for water and petrol pipes, as well as trembler blades, for both wipe and make and break commutators.

The chief feature of the accessories shown by Messrs. Brown Brothers is the autoclipse lamp; these lamps produce two distinct sets of rays, one to light the road its full width near the car, the other to project for a long distance. The long distance rays can be cut out when desired without affecting the ordinary light. In traffic by means of a small pedal all excessive glare can be immediately suppressed and when needed the full illuminating power can be resumed. It seemed to me that these lamps supplied a want of the medical motorist, especially in the country, where night trips in non-lighted country lanes may often have to be undertaken. Messrs. Brown also show a useful brake lining "raybestos" which is made of asbestos woven with brass wire and will neither burn nor carbonise in any heat. A good many people still have cars with band brakes that are lined and for these this lining will be found most efficacious; it should be attached by countersunk screws, the ends of which should be well burred over. Some drivers like a musical alarm horn; if so, they will find the Gabriel, also shown on this stand, certainly a musical one. It is worked off the exhaust gases. Occasionally it is needful to alter or replace the radiator of a car, and those who are thinking of so altering their water-cooling apparatus should inspect the manufactures of the Coventry Motor Fittings Company who in addition to the honeycomb radiator have a variety of bonnets, silencers, wings, and oil-tanks on view.

An enormous number of lubricating oils are shown, and in addition most motorists constantly receive circulars about lubricating oils and greases, and what astonishes me is the difference in price. All the makers claim increase of friction-reducing capacity, with diminished carbonising tendency; all also claim that the viscosity is such that at working temperatures they are efficient lubricants, and that their flash-point is so high that they are not liable to volatilise in the cylinder with the production of smoke. Well, medical men can easily roughly test these claims for themselves; all that is needed is the ordinary apparatus, which we all have for estimating sugar in urine, and a thermometer. I think it can be taken that if the flash-point is not far short of 500°, the oil will do for petrol engines. Take a little of the oil, heat in a porcelain dish over a bunsen flame, and stir the oil with a thermometer; occasionally bring a lighted taper near to the heated oil, if there is no blue flame—that is, if it does not flash until the thermometer is near 500°, that oil can pass muster. Another test is to see how long a certain quantity takes to run out of a burette drawn out to a fine point, and to compare the time with that taken by a similar quantity of a known good oil; if there is a great difference at the same temperature, and the oil flashes at much under 400°, reject it, even if it is given to you free of charge. It is cheaper to pay for the lubricant than to be constantly taking off the cylinders to clean away soot, the cause of pre-ignition.

The serisol terminals shown by J. Lacoste and Co. are most useful; they merely push on and contact is made and they can be released as easily. Anyone who has spent a few moments in trying to connect up a lead to a coil terminal, especially when it is underneath, will appreciate not to have to use the box spanner and nuts. These insulated terminals are adapted for coils, plugs, commutators, and accumulators. Coils trembler and non-trembler for one, two, three, and four-cylinder engines are also shown. These are fitted with the lumen trembler, which consists of two blades of different temper rivetted together, but with a space between, so that when the current is passed in the induction circuit the bottom blade is drawn to the core, but the upper one is left in contact for a shade longer and then it descends and the circuit is cut, the induced current accumulating until that time, and so the rapidity of breaks is great and the spark of good quality, and sticking of the trembler rarely occurs.

The British Bariquand and Marre Engine Company show types of their four- and six-cylinder engines. Their fitments show the care and accuracy employed, the exhaust valve lifter with hardened rollers, the perfectly ground crank shafts, and the excellent fit of the pistons. Their automatic carburettor is fitted with a primary air orifice at the side and in the spray chamber are four triangular ports normally shielded by a piston that slides up and down the chamber, so that as the suction increases this auxiliary air-supply is brought into action.

Another engine which is bound to attract attention is the White and Poppe. The crank shafts are of the built-up type and phosphor-bronze bearings are provided between each crank web. The gudgeon pin is a drive fit and a ring is sprung over to prevent any possibility of scoring. Hardened rollers are fitted to the valve lifters. Ignition is by Simms Bosch magneto.

Messrs. Benton and Stone show some excellent lubricators that can be employed either with the exhaust or forced feed type. The glasses are easily removed for cleaning and can be replaced in a few moments, and in addition a small electric glow lamp is fitted that illuminates the drips at the will of the driver.

Another interesting exhibit is that of Messrs. Willans and Robinson, Limited, who show crank shafts of vanadium steel clear and the whole work gives promise of being so important an addition to the literature of syphilis that we look forward with interest to the appearance of the remaining volumes.

Attention. By W. B. PILLSBURY. London: Swan Sonnenschein and Co. 1908. Pp. 346. Price 10*s.* 6*d.*

THIS work forms an elaborate endeavour to bring together in an orderly way the results of different researches, and the theories resulting therefrom, on the subject of the attention. Mr. Pillsbury defines attention, from the standpoint of its conscious characteristics, as an increased clearness and prominence of some one idea, sensation, or object, whether remembered or directly given from the external world, so that for the time it is made to constitute the most important feature of consciousness. This central position of the process in question depends upon two general factors, the present environment on the one side and the entire past history of the individual on the other. Nor is man's experience only composed of the comparatively few events which have brought him into direct contact with nature, but through tradition and books he has summed up within himself the entire experience of the human race. Through heredity also it may be possible to trace some small number of the conditions which have to be taken into consideration in explaining any act of attention back to the acts and surroundings of his predecessors in the course of evolution. The physiological processes which are peculiar to attention are reinforcement or facilitation and inhibition. Reinforcement is defined as increase in the activity of one nerve cell by the action of another cell or cells not in the direct line of transmission, while inhibition is a mutual opposition of two cells in their activity. It seems probable that the anatomical seat of attention is in the frontal lobes. These are not indeed the seat of spontaneous energy but are the association centres that mediate between sensory, and sensory and motor, areas of the cortex. The degenerations of mind are nearly all accompanied by weakened or deranged attention, and in insanity two forms of change may be noted, the general instability that forbids any concentration, as in mania, and the distorted attention that gives rise to fixed ideas, as in paranoia.

Attention is of importance in memory. What is remembered at any moment is dependent upon the objective and subjective setting of that moment. The ease with which an event is recalled is largely due to the interest with which the impression was received in the first place and to the way in which it fitted in with the other elements in consciousness at that period. An impression received in one way at its first entrance may take on an entirely different aspect when it reappears. New interpretations may be given to it, new meanings put upon it, because of the new knowledge which has been received between the times of the first and second entrance. In every way then is memory influenced by attention, and its conditions as a whole are very similar to the conditions of attention.

The author concludes his work with an interesting chapter upon the applications of the theory of the attention to education. The first problem which meets the teacher is how to hold the attention of the pupil, and if this can be satisfactorily accomplished everything else will be comparatively simple. The question is, What is likely to hold the attention of a particular child? The only answer, according to the author, that can be given is in terms of the earlier history of the child. Anything will be interesting that the child knows something about and which is neither too old nor too new, which can in some way be attached to the pupil's earlier experiences and at the same time is new enough not to seem commonplace. Furthermore, the new material must be presented in such a way that the connexions with the older elements shall come out prominently. The first condition for the teacher is to know the child, and this knowledge must be not only statistical but also sympathetic. It must include some knowledge of the home life of the child and, ideally, of his parents also. But to decide what shall be taught to a child in terms of his interests alone is but one side of the question. The aim of education is to mould the child for useful participation in the life of the community, and the test which every scheme proposed must meet is whether it puts the child in possession of those portions of traditional knowledge which shall most thoroughly prepare him for life in the community, and to arrive at this end the attention of the child must be held to all those elements of knowledge which are essential to his individual progress and any influence which can be regarded as the natural determinants of attention must be used.

Mr. Pillsbury's work is an exhaustive one and should be of very considerable interest to those concerned in psychological and educational problems. His subject-matter necessarily consists in the treatment of highly abstract ideas, but he has made judicious use of such elementary positive knowledge of the operations of mind as we possess and has represented his data and theories in a style of much literary merit.

LIBRARY TABLE.

Encyclopædia of Local Government Board Requirements and Practice. Being an Encyclopædia of the Requirements and Practice of the Local Government Board in connexion with Applications to Them, including a Summary of the Statutory Provisions Governing each Matter dealt with. By A. E. WOOD and T. R. JOHNSON. In two volumes. Vol. I., pp. 452 + 55; Vol. II., pp. 435 + 55; total, pp. 887 + indexes. London: Butterworth and Co. and Shaw and Sons. 1908.—It is only those who are brought officially into contact with the Local Government Board who have any proper conception of the enormous scope of the Board's duties or of the intricate nature of the multitudinous matters with which it deals. Even those, like medical officers of health, clerks to local authorities, members of district councils and of boards of guardians who are in touch with certain aspects of local government find themselves bewildered by the numerous orders, circulars, and explanatory notices which are issued annually by the Board in connexion with new and old statutes and in modification of existing practices and interpretations. It is with a view to reduce chaos to some semblance of order and to facilitate the work of local officials that the two volumes now under review have been written, and although the work cannot, of course, be regarded in any sense as an official publication, it has the merit, for in the circumstances it is a distinct advantage, that the authors are themselves on the clerical staff of the Local Government Board and thus the book is given a certain *cachet* which it might not otherwise possess. The two volumes are together divided into 59 parts, each part dealing with a particular subject, such, by way of example, as arbitrations under the Public Health Act, 1875, boarding out of pauper children, borrowing, burial grounds, commons and open spaces, emigration, housing of the working classes, provisional orders, sea defences, telephonic systems, workhouses, water-supply, and, in fact, all matters concerned with local government. Each part deals with every aspect of the subject and indicates the procedure which should be adopted to conform with the statutes and with the practice of the Local Government Board; it comprises also the Parliamentary papers relating to each subject. The whole is well got up and capitally arranged and the volumes possess in addition the great advantage of lightness in weight. The authors have, we think, succeeded

One possible source of the disease which fell under suspicion was certain bales of rags brought round from Newcastle, the time of the arrival of the rags coinciding with the average period of incubation of plague, and there are good reasons to think that the mate may in some way have come in contact with them. The rags in question, however, had been dealt with in Liverpool and no one who handled them was any the worse for it. Moreover, as soon as they were unpacked they were dealt with in a carboniser, a process subjecting them to a high temperature and the intense fumes of hydrochloric acid. All hands at the mills remain well. The source of origin of the first case, therefore, is extremely obscure but the origin of the two other cases is abundantly evident, these persons having obviously been infected on the barge. There is very little reason to apprehend that anything further will arise in connexion with this particular outbreak and it seems hardly necessary to say that the main importance of the incidents arises not from any effect upon the public health which may ensue but from the great commercial injury which may be done to the port unless every care and discretion are exercised.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE twenty-third annual meeting of the Fellows and Members of the Royal College of Surgeons of England was held at the College on Nov. 19th. Mr. HENRY MORRIS, the PRESIDENT, was in the chair and 15 other members of Council were present. The meeting was large and it included 13 Fellows in addition to the Council and 115 Members.

The proceedings were commenced by the PRESIDENT presenting to the meeting the annual report of the Council of the College on the work of the College for the past academical year; it contained references to many matters of interest, and especially it included replies to, and comments on, the resolutions carried at the 1907 meeting of Fellows and Members. The President proceeded to mention most of the items in the report, commenting on them as he came to each. One of the more important matters transacted during the year was the poll of the Fellows and Members on the question of the admission of women to the examinations of the College.

Dr. WALTER SMITH then introduced the first item on the agenda. He asked, "How many diplomas of deceased Fellows, Members, and Licentiates who have died during the past year have been returned to the College and what steps, if any, have been taken to insure they be returned or improper use be not made of them?" Dr. Walter Smith stated that to his knowledge many diplomas of deceased Members of the College were being employed fraudulently and he thought that the Council should endeavour to obtain the return of the diplomas of deceased Members by applying to the relatives, and he was anxious to know if the Council was taking any steps to prevent the misuse of these diplomas.

In reply the PRESIDENT stated that he had heard of a few cases where the diplomas of deceased Members of the College had been used by unqualified persons, but he had no knowledge of the fact as stated by Dr. Walter Smith that the practice was at all common. As to the question if any action was being taken by the Council to insure the return of disused diplomas, he informed the meeting that every diploma of the College had attached to it a slip of paper on which was a request that the diploma might be returned at the death of the Member and the Council hoped that this would be productive of good. In reply to further questions the PRESIDENT stated that this practice of attaching the slip to each diploma had been in use only about a year and that during the past year only one diploma had been returned on the death of a Member.

The President was asked if any steps were being taken in reference to the proposed coöperation between the two Royal Colleges and the University of London, and if the holders of the present Conjoint diplomas would be entitled to the degrees of M.B. and B.S. In reply, the PRESIDENT stated that negotiations were proceeding and that if they arrived at any arrangement the future holders of the diplomas of M.R.C.S. and L.R.C.P. would also have the degrees of M.B. and B.S., but the arrangement would not be retrospective.

The PRESIDENT then called upon Mr. JOSEPH SMITH to introduce the first motion which was in these terms:—

> That this meeting thanks the Council for having for the first time in its history taken a poll of the Members of the College but regrets that the Council found itself unable to abide by the result. This meeting also trusts that the Council will shortly take a further poll of the Fellows and Members on the question of Direct Representation of Members as requested by the last annual meeting.

Mr. Joseph Smith thanked the Council for its action in taking a poll of the Members, and also for relieving the Members of all responsibility in regard to the admission of women to the examinations of the College, for, as the Council had acted in direct opposition to the votes of the majority, the Council alone was responsible. He hoped that that was only the beginning of polls of the Members; one common argument put forward against polling the Members was the great cost; but the expense was not very great, for it had cost only about £110. In regard to the second part of the motion he claimed that the Council, though composed of good surgeons, could not be in touch with the general practitioners. For 23 years this motion had been brought forward and carried every year by enormous majorities or unanimously but the Council had not taken any action in the matter. He was as anxious as anyone could be to put an end to this internal dispute in the College, and the dispute could be ended at once by admitting a certain number of Members on to the Council. Four Members on the Council or even eight Members would always be a small minority, and therefore they could never in the least degree control the action of the Council, but if Members were on the Council they could give valuable information as to the feelings and wishes of the general practitioners of the country; for instance, the action of the Council in the matter of the Midwives Bill was in opposition to the wishes of the great majority of general practitioners. He hoped that before long this small boon would be granted to the Members and when that had been *done*, and the Members were represented on the Council, then the President would indeed be the President of the College as a whole and not of the Fellows only.

Dr. SIDNEY C. LAWRENCE seconded the motion. He remarked that he thanked the Council for taking the poll and especially for showing how to take an incomplete and inaccurate poll. More than 3000 Members had received no card at all and 37 per cent. had received two cards apiece. He could not understand why 92 votes should be rejected merely because of a few added words. The Council had absolutely contemned the majority of 703 Members, and it had in effect said that it cared nothing for the opinions of the Members. The Council appeared to have forgotten that in 1895, at the annual meeting of Fellows and Members, a proposal to admit women to the examinations of the College was rejected by a large majority. The Council on that occasion acquiesced in the opinion of the meeting, but in this year the opinion of the Fellows and Members was asked and then rejected. As to the question of the representation of Members on the Council, when the Council took a poll of the Fellows, a large proportion of the Fellows voted for the representation of the Members. There were many reasons why the Members should be represented on the Council. First, there were many questions affecting the Members only, and these could be adequately dealt with only by Members; secondly, questions affecting general practitioners could not be understood by consultants; and thirdly, if there were Members on the Council they would serve as a channel of communication between the Council and the Members. The appointment of general practitioners on the General Medical Council had not revolutionised the business of that Council.

Dr. MICHAEL BEVERLEY moved an amendment to omit the words, "but regrets that the Council found itself unable to abide by the result." He considered that the College of Surgeons had done justice to a large body of women in admitting them to the examinations of the College. Medical women had been admitted into the British Medical Association and no harm had resulted. No harm could result from their admission to the College. He failed to see why Members should take exception to the admission of women.

Dr. D. A. HAYDEN seconded the amendment.

Mr. F. W. COLLINGWOOD expressed his agreement with the admission of women but that was not the question; the real point in the motion was whether the Council should or should not have gone in opposition to the vote of the Members.

clear and the whole work gives promise of being so important an addition to the literature of syphilis that we look forward with interest to the appearance of the remaining volumes.

Attention. By W. B. PILLSBURY. London: Swan Sonnenschein and Co. 1908. Pp. 346. Price 10s. 6d.

THIS work forms an elaborate endeavour to bring together in an orderly way the results of different researches, and the theories resulting therefrom, on the subject of the attention. Mr. Pillsbury defines attention, from the standpoint of its conscious characteristics, as an increased clearness and prominence of some one idea, sensation, or object, whether remembered or directly given from the external world, so that for the time it is made to constitute the most important feature of consciousness. This central position of the process in question depends upon two general factors, the present environment on the one side and the entire past history of the individual on the other. Nor is man's experience only composed of the comparatively few events which have brought him into direct contact with nature, but through tradition and books he has summed up within himself the entire experience of the human race. Through heredity also it may be possible to trace some small number of the conditions which have to be taken into consideration in explaining any act of attention back to the acts and surroundings of his predecessors in the course of evolution. The physiological processes which are peculiar to attention are reinforcement or facilitation and inhibition. Reinforcement is defined as increase in the activity of one nerve cell by the action of another cell or cells not in the direct line of transmission, while inhibition is a mutual opposition of two cells in their activity. It seems probable that the anatomical seat of attention is in the frontal lobes. These are not indeed the seat of spontaneous energy but are the association centres that mediate between sensory, and sensory and motor, areas of the cortex. The degenerations of mind are nearly all accompanied by weakened or deranged attention, and in insanity two forms of change may be noted, the general instability that forbids any concentration, as in mania, and the distorted attention that gives rise to fixed ideas, as in paranoia.

Attention is of importance in memory. What is remembered at any moment is dependent upon the objective and subjective setting of that moment. The ease with which an event is recalled is largely due to the interest with which the impression was received in the first place and to the way in which it fitted in with the other elements in consciousness at that period. An impression received in one way at its first entrance may take on an entirely different aspect when it reappears. New interpretations may be given to it, new meanings put upon it, because of the new knowledge which has been received between the times of the first and second entrance. In every way then is memory influenced by attention, and its conditions as a whole are very similar to the conditions of attention.

The author concludes his work with an interesting chapter upon the applications of the theory of the attention to education. The first problem which meets the teacher is how to hold the attention of the pupil, and if this can be satisfactorily accomplished everything else will be comparatively simple. The question is, What is likely to hold the attention of a particular child? The only answer, according to the author, that can be given is in terms of the earlier history of the child. Anything will be interesting that the child knows something about and which is neither too old nor too new, which can in some way be attached to the pupil's earlier experiences and at the same time is new enough not to seem commonplace. Furthermore, the new material must be presented in such a way that the connexions with the older elements shall come out prominently. The first condition for the teacher is to know the child, and this knowledge must be not only statistical but also sympathetic. It must include some knowledge of the home life of the child and, ideally, of his parents also. But to decide what shall be taught to a child in terms of his interests alone is but one side of the question. The aim of education is to mould the child for useful participation in the life of the community, and the test which every scheme proposed must meet is whether it puts the child in possession of those portions of traditional knowledge which shall most thoroughly prepare him for life in the community, and to arrive at this end the attention of the child must be held to all those elements of knowledge which are essential to his individual progress and any influence which can be regarded as the natural determinants of attention must be used.

Mr. Pillsbury's work is an exhaustive one and should be of very considerable interest to those concerned in psychological and educational problems. His subject-matter necessarily consists in the treatment of highly abstract ideas, but he has made judicious use of such elementary positive knowledge of the operations of mind as we possess and has represented his data and theories in a style of much literary merit.

LIBRARY TABLE.

Encyclopædia of Local Government Board Requirements and Practice. Being an Encyclopædia of the Requirements and Practice of the Local Government Board in connexion with Applications to Them, including a Summary of the Statutory Provisions Governing each Matter dealt with. By A. E. WOOD and T. R. JOHNSON. In two volumes. Vol. I., pp. 452 + 55; Vol. II., pp. 435 + 55; total, pp. 887 + indexes. London: Butterworth and Co. and Shaw and Sons. 1908.—It is only those who are brought officially into contact with the Local Government Board who have any proper conception of the enormous scope of the Board's duties or of the intricate nature of the multitudinous matters with which it deals. Even those, like medical officers of health, clerks to local authorities, members of district councils and of boards of guardians who are in touch with certain aspects of local government find themselves bewildered by the numerous orders, circulars, and explanatory notices which are issued annually by the Board in connexion with new and old statutes and in modification of existing practices and interpretations. It is with a view to reduce chaos to some semblance of order and to facilitate the work of local officials that the two volumes now under review have been written, and although the work cannot, of course, be regarded in any sense as an official publication, it has the merit, for in the circumstances it is a distinct advantage, that the authors are themselves on the clerical staff of the Local Government Board and thus the book is given a certain *cachet* which it might not otherwise possess. The two volumes are together divided into 59 parts, each part dealing with a particular subject, such, by way of example, as arbitrations under the Public Health Act, 1875, boarding out of pauper children, borrowing, burial grounds, commons and open spaces, emigration, housing of the working classes, provisional orders, sea defences, telephonic systems, workhouses, water-supply, and, in fact, all matters concerned with local government. Each part deals with every aspect of the subject and indicates the procedure which should be adopted to conform with the statutes and with the practice of the Local Government Board; it comprises also the Parliamentary papers relating to each subject. The whole is well got up and capitally arranged and the volumes possess in addition the great advantage of lightness in weight. The authors have, we think, succeeded be said about split foot and non-split foot. Three pedigrees of albinism had been put on the board, compiled by Dr. Magnus, concerning albinism in Norway; and Dr. Magnus was a very careful observer and very catholic in his views, so he sent a copy to Professor Bateson and asked him if he conformed to his view, and a copy to himself (Professor Pearson) and asked him if it agreed with his view. In those 30 pedigrees the conditions required by Mendelism failed utterly. It was of no use showing one or two on the board; the whole number should be taken. He had cases in which an albinotic woman had married two husbands who were not related to her nor to each other. The offspring of both parents were albinos. According to Mendel, both those stocks ought to have albinism in a recessive form. The chances against that could be calculated because albinism occurred in Norway in about 1 in 20,000 of the population; in Scotland 1 in 24,000. What were the chances that an albino woman would marry two affected stocks with albinism not related to her and not related to each other? He had no less than four or five such cases. He had the case of a negress who was normal. She married first a Frenchman and had an albino child. She then married a negro and had an albino child. He did not say there was any proof against Mendelism but that at present there were not available the data to judge by. It was necessary to increase the material over and over again and to get good material. Facts were the important thing. He believed that the only service which had been done by Mendel and his followers was to show the importance of noticing segregation. That held true, and there was some segregation taking place in the offspring of the second generation. The inquiry had done great service in setting very many people experimenting and collecting but it was yet too early to generalise on the facts obtained.

Professor **BATESON** here pointed out that he had shown a pedigree as an example which did not conform to Mendel's rules.

Professor **PEARSON** said that he was very glad to hear that. With regard to Dr. Latham's paper, Dr. Latham seemed to suppose that a certain degree of immunity was acquired and that that immunity was inherited. He did not understand him to say that in stating that he was accepting the hypothesis of the inheritance of acquired characters. But if that was to be said it was time to make a strong statement that it differed from the whole of the present biological tendency. And if it was true he feared Mendelism of every form collapsed. With regard to the actual problem being discussed, that of inheritance of a constitution, he thought it conceivable that the weakness of the constitution could lie in one particular organ, and therefore when he came to touch the subject of tuberculosis he carefully inquired among men with considerable experience whether it was desirable to club together all forms of tubercle, and the opinion given to him was that it was desirable to keep pulmonary tuberculosis apart from other forms. If that were done, and one said the constitution was inherited, what would be the effect of that? By leaving out the other forms one weakened the intensity of inheritance. To argue that they had been left out only meant that there ought to have been a far higher degree of inheritance than was found. All Dr. Latham's criticisms applied to that: that if the statistics were bad they ought to increase the strength of the inheritance; there should be a spurious value. But every time the statistics were weakened one approached more nearly to the problem of picking up random men in the street and arguing that if they had both got the disease they must be correlated together as father and son. That would bring relationship to zero. A question arose in his own mind whether the points made by Dr. Mercier as to the reduction of the disease were not really due to survival of the fitter. The view would not be very acceptable in that gathering, because the medical man liked to feel that the reduction in the cases was due to his efforts. He (Professor Pearson) was not sure that it was not largely due to the prevalence of tuberculosis in the last few generations. Dr. Mercier said that if there were 50 per cent. when the record was completed of offspring of tuberculous parents, then tuberculosis ought to increase. Why? His own view was that if the population was suitable there would be the same proportion of tuberculous people in the next generation. 50 per cent. of the children of tall parents might be tall, but it did not follow that the whole population was becoming taller. While the fraternities of the tuberculous were very large, averaging 6 and running up to 12 and 15, the offspring of the tuberculous gave a much less number of children. In other words, however late one might be postponing the period at which tuberculosis produced death, the period at which the oncome of the disease occurred was still from 25 to 28 years. He admitted that he appeared to be very dogmatic, but a little dogmatism was a good thing, it stirred people up to think and to inquire, and what was much wanted at the present day was to get a wave of inquiry in the medical profession, that its members would spend time and care, not in asking questions of hospital patients whom they saw only occasionally but in following up cases carefully. The formation of pedigrees was not easy, every pedigree was almost a work of art, and under those conditions it possessed a permanent value. If only one medical man in ten would once in their life collect two pedigrees, then in the course of the next generation there would be all the material necessary to answer those questions.

Dr. J. **EDWARD SQUIRE** said in regard to heredity in relation to pulmonary tuberculosis that tuberculosis, being the result of a bacterial infection, was not in itself a hereditary disease; it was only the predisposition to suffer from the infection which could be considered in relation to heredity. Undoubtedly there was a susceptibility to tuberculous infection in human beings differing in degree from that of other animals. That racial susceptibility was no doubt passed on by heredity. The point which they had to consider was whether there was in addition a special degree of susceptibility or predisposition affecting certain individuals which was transmitted from tuberculous parents to their offspring. In many diseases common to mankind, such as measles, certain individuals and certain families tended to suffer more than others, not only in the susceptibility to infection, but also in the severity of the resulting illness. That applied to tuberculosis. Was that greater degree of susceptibility a specific inherited peculiarity and was it of sufficient potency to constitute an important etiological factor of the disease? The question was important from the point of view of preventive medicine. No one would be prepared, he took it, at the present time to deny that various causes outside heredity—such as environment, previous illnesses, &c.—influenced the susceptibility of the individual to suffer from infection by the tube bacillus and the relative influence of such conditi required to be determined in each case before it possible to assess the possible influence of heredity. I the investigation of heredity in human beings they w of necessity restricted to statistics based on the exami tion of pedigrees. When one person in every ten w or had been affected with a given condition—and tub culosis was at least as common as that in this country it was hardly safe to infer a special inherited influen because they found instances of the condition in sever generations of any family unless they could show the com parative rarity of the condition in the majority of familie Even when the facts could be accurately ascertained, which i regard to tuberculosis was extremely difficult, only a traine statistician could manipulate them with advantage. Som years ago he published[1] some figures in connexion with heredity in consumption which he would summarise briefly. His statistics—if they might be dignified by that term—possessed all the fallacies which were inherent to investigations of that nature, but such as they were they served a useful purpose. When he published them the belief that consumption was essentially an inherited disease was widely prevalent. As evidence which tended to show that heredity was not all-powerful and that environment was a potent etiological factor they had, he believed, a certain value. Briefly he showed that in 1000 families, comprising 6457 children, whilst 33·16 per cent. of the children of phthisical parents became tuberculous, 23·65 per cent. of the children of non-phthisical parents in a similar rank of life developed the disease—a difference of less than 10 per cent. to represent possible hereditary influence. When the greater risk of infection run by those children who lived with consumptive parents was considered it seemed that the hereditary influence could not be very great. It was true that when both parents were tuberculous the percentage of tuberculous individuals amongst

---

[1] Transactions of the Royal Medical and Chirurgical Society, 1894, and American Journal of the Medical Sciences, November, 1897.

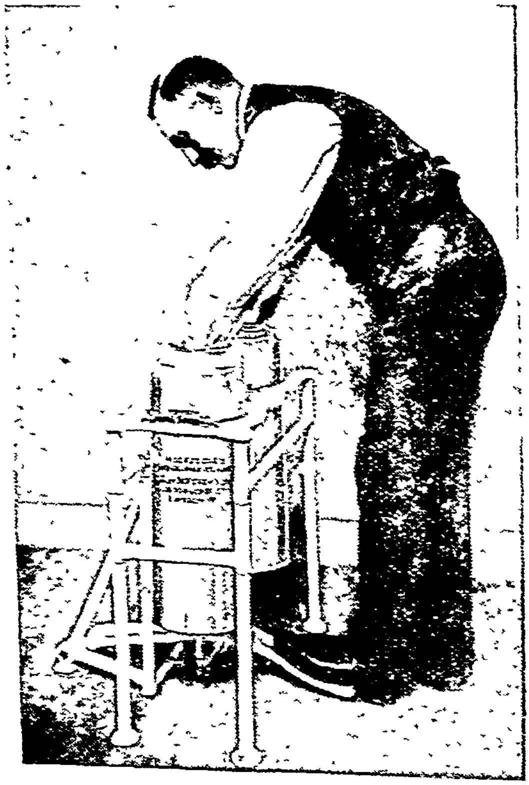
The Medical Chronicle.—The November number contains only one original communication, an article on Post-Anæsthetic Acidosis, or Delayed Chloroform Poisoning, by Mr. Hugh T. Ashby. The author notes that the condition is almost confined to children and may follow the administration of chloroform for quite small operations. He favours the view that the acidosis which occurs is due to the presence of β-oxybutyric and diacetic acids formed from fat existing in the liver, a fatty condition of which organ may be caused by rickets. By way of treatment sodium bicarbonate should be pushed till the urine becomes alkaline.

The Birmingham Medical Review.—In the October issue Dr. T. Stacey Wilson advocates the employment of reverberation—a modified form of auscultatory percussion—for the diagnosis of gastric dilatation and the use of massage for the treatment of atonic states of the stomach. Mr. A. W. Nuthall writes on Acute Pneumococcal Peritonitis, which he regards as due to a general blood-infection, and gives notes of three cases; and Dr. Otto J. Kauffmann records two cases in which a condition was found suggestive of a relationship to status lymphaticus. The characteristic phenomenon of sudden death did not, however, ensue.

New Inventions.

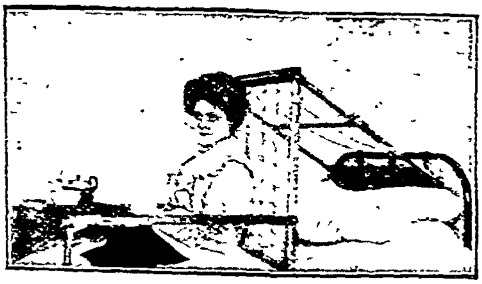
AN "AUTO-GLOVING MACHINE."

WE have recently examined an "Auto-Gloving Machine" manufactured by C. A. Hoefftcke, Limited, 21, Woodstock-street, London, W., after a design suggested by a London surgeon. It is an ingenious contrivance of somewhat formidable appearance, but is made so as to form a quite suitable piece of furniture for an operation-room. Its object is to provide means whereby indiarubber gloves can be put on without being touched on the outer surface by the hands. The apparatus consists essentially of a cylinder which can be partially exhausted by a piston worked by a pedal. At the top of the cylinder is a flanged rim, over which the wrist of the glove is stretched and fixed with the fingers hanging vertically into the cylinder; the glove thus when in this position completely closes the upper aperture, forming, as it were, a dependent diaphragm. When the operator treads on the pedal the air-tight piston is pulled downwards, producing a partial vacuum in the metal tube and the difference in the atmospheric pressure thus produced stretches the gloves to the size of a boxing glove with wide fingers and thus enables the hands to be inserted easily into them. At the same time an automatic catch under the pedal fixes the piston. When the hands are in the gloves, by treading on the pedal air is admitted into the metal tube and the gloves contract upon the hands with a sudden snap. This action also releases the catch and the spring attached to the pedal forces the piston upwards and the air releases the gloves from the upper end of the apparatus. The hands with the gloves applied can then be withdrawn. The appliance, which is made of plated metal, is simple in construction. It can be taken to pieces quite easily and every part sterilised. The gloves are stretched evenly over the whole surface by the minus air pressure, and in consequence there is no danger of the gloves being torn. A pair of gloves can be put on in a few seconds by anyone accustomed to the machine, and the gloves can be either wet or dry. The appliance is made single or double. When using the single-glove machine one glove is put on at a time, and with the double-glove machine both gloves are put on at once.



A COMBINATION BED-REST FOR INVALIDS.

Mr. James Taylor has brought to our notice a new combination bed-rest which he has invented and which has been made for him by Messrs. Braun and Co., 1, Northdown-street, King's Cross. It consists of a light wooden frame, which can be clamped to the back of bedsteads of varying designs. This frame incloses a back-rest made of spring mattress wire which can be inclined at any angle comfortable to the patient. When out of use it rests upright above the back of the bed and it can be swung down into position behind the patient's back without disturbing the pillows. A slight push of the hand suffices to return it to its "off-duty" position, a manœuvre which can be effected by a convalescent patient. A special feature of the device is that the bed-rest is accommodated to the patient and not the patient to the bed-rest. The stability of the back-rest is obtained by a weight consisting of a small water-tank, which is attached to the back of the rest by two cords passing over pulleys fixed to the back of the bed, below which the weight hangs. This device renders the inclination of the back-rest to any desired angle an easy matter. An accessory feature is a tray which folds up over the frame of the back-rest and, as shown in the figure, can be brought down over the patient's head into a convenient position for the service of meals; by the release of a spring it can be tilted to a slight degree to form a sloping desk for reading and writing. The inventor claims for the bed-rest lightness, comfort, and compactness, and after examining it we have formed the opinion that this claim is justified and that it will make a useful accessory for the sick-room.



returned during the week in London and its suburban districts and five in Liverpool. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily increased in the ten preceding weeks from 2855 to 3861, had declined to 3809 on Saturday, Nov. 21st; the new cases of this disease admitted to these hospitals during the week under notice was 421, against 507, 512, and 500 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily increased in the five preceding weeks from 159 to 310, further rose last week to 334, but were 52 below the corrected average number in the corresponding week of the five years 1903–07. The causes of 36, or 0·7 per cent., of the deaths registered during last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were again duly certified in London, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 52 other smaller towns; the 36 uncertified causes of death in the 76 towns included, however, 12 in Liverpool, five in Birmingham, three in Sheffield, and two in Manchester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15·4 and 16·9 per 1000 in the two preceding weeks, further rose to 17·3 in the week ending Nov. 21st. During the first eight weeks of the current quarter the annual death-rate in these eight towns averaged 14·8 per 1000, and exceeded by 0·3 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 10·4 and 14·0 in Paisley and Edinburgh, to 21·0 in Dundee and 22·8 in Leith. The 610 deaths in the eight towns showed a further increase of 13 upon the numbers returned in the two previous weeks, and included 62 which were referred to the principal epidemic diseases, against 55 and 68 in the two preceding weeks; of these 62 deaths, 22 resulted from diarrhœa, 16 from whooping-cough, nine from diphtheria, eight from scarlet fever, five from "fever," and two from measles, but not one small-pox. These 62 deaths were equal to an annual rate of 1·8 per 1000, which exceeded by 0·4 the mean rate from the same diseases in the 76 English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had been 34, 29, and 24 in the three preceding weeks, further declined to 22 in the week under notice, and included 10 in Glasgow, four in Aberdeen, and two each in Edinburgh, Dundee, Leith, and Greenock. The 16 fatal cases of whooping-cough were within one of the number in the previous week; 12 occurred in Glasgow, and two both in Edinburgh and in Aberdeen. The nine deaths from diphtheria, of which six were returned in Glasgow, showed a slight decline from the numbers in recent weeks. The eight fatal cases of scarlet fever corresponded with the number in the previous week, including five in Glasgow and one each in Edinburgh, Dundee, and Leith. The five deaths referred to "fever," of which four were certified as enteric, were all recorded in Glasgow. Two deaths from measles were returned, including one in Glasgow and one in Aberdeen, no death from this disease having been recorded during the three preceding weeks. The deaths referred to diseases of the respiratory organs in the eight towns, which had increased from 56 to 126 in the four preceding weeks, further rose to 136 in the week under notice, and exceeded by 29 the number returned in these towns in the corresponding week of last year. The causes of 13, or 2·1 per cent., of the deaths registered during the week in the eight towns were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 0·7 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 20·4, 23·8, and 19·3 per 1000 in the three preceding weeks, rose to 24·2 in the week ending Nov. 21st. During the first eight weeks of the current quarter the death-rate in the city averaged 19·4 per 1000, whereas the mean rate during the same period did not exceed 14·5 in London and 13·3 in Edinburgh. The 183 deaths of Dublin residents during the week under notice exceeded the number returned in any week since the middle of May last, and included 21 which were referred to the principal epidemic diseases, against 15 and eight in the two preceding weeks. These 21 deaths were equal to an annual rate of 2·8 per 1000; the rate from these diseases in the same week did not exceed 1·1 in London and 0·7 in Edinburgh. Of the 21 deaths from these epidemic diseases in Dublin last week, eight resulted from measles, four from "fever," four from whooping-cough, four from diarrhœa, and one from diphtheria, but not one either from scarlet fever or small-pox. The eight fatal cases of measles showed a marked increase upon the numbers returned in recent weeks; and those referred to "fever" and whooping-cough also showed some increase. The 183 deaths from all causes during the week included 32 of infants under one year of age and 46 of persons aged upwards of 60 years; both these numbers showed an increase upon those returned in the previous week. Four inquest cases and two deaths from violence were registered, and 59, or 32·3 per cent., of the deaths occurred in public institutions. The causes of three, or 1·6 per cent., of the deaths in Dublin last week were not certified; the proportion of uncertified causes of death in Edinburgh last week was equal to 3·3 per cent., while in London the cause of each of the 1357 deaths was duly certified.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1908.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 9·2 per 1000 of the population, estimated at 4,795,757 persons in the middle of the year; in the three preceding months the rates were 6·5, 6·3, and 8·6 per 1000 respectively. The lowest rates last month were recorded in Hammersmith, Chelsea, Hampstead, Holborn, and the City of London; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Deptford. Scarlet fever was rather less prevalent than in other recent months; among the several metropolitan boroughs the greatest proportional prevalence of this disease occurred in Paddington, Shoreditch, Bethnal Green, Stepney, Poplar, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 2693, 2807, and 3431 at the end of the three preceding months, had further risen to 3776 at the end of October; the weekly admissions averaged 493, against 372, 365, and 506 in the three preceding months. The prevalence of diphtheria showed a marked increase last month; this disease was proportionally most prevalent in Fulham, Chelsea, Bethnal Green, Bermondsey, Battersea, Greenwich, and Lewisham. The Metropolitan Asylums Hospitals contained 1118 diphtheria patients at the end of last month, against 738, 843, and 953 at the end of the three preceding months; the weekly admissions averaged 158, against 100, 110, and 128 in the three preceding months. Enteric fever also was much more prevalent than in other recent months; the greatest proportional prevalence of this disease was recorded in the City of London, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. There were 145 enteric fever patients under treatment at the end of last month, against 54, 69, and 95 at the end of the three preceding months; the weekly admissions averaged 24, against nine, 12, and 18 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Shoreditch, Bethnal Green, Stepney, Bermondsey, Deptford, and Greenwich. The 25 cases of puerperal fever notified during the month included four belonging to Bermondsey, three to Hackney, three to Poplar, two to Paddington, and two to Kensington. Of the eight cases notified as cerebro-spinal meningitis two belonged to Islington, and one each to Westminster, St. Marylebone, and Wandsworth.

table relate to the deaths of
various boroughs, the deaths
occurring in institutions having been distributed among the

however, were enormous—namely, from 40 to 70 grains. Of the other worthies commemorated by Professor OSLER we have no space to speak here but the biographies show that in all ages the earnest student will come to the front, that with all their imperfections and their limitations of knowledge the men of olden days made valuable contributions to medical science, and to one who reads their writings it will be apparent that they cherished high ideals.

BASSETT in one of his papers has left a striking passage upon the study of medicine. He compares it to the study of a foreign language, which he says no one can be said really to know until he can talk with and understand all classes. He proceeds: "Let him then sit down and calculate the cost in time, labour, and talent; then square the amount and go boldly into the study of physiology; and when he has exhausted his programme, he will find himself humbly knocking at the door of the temple and it will be opened; for diligence, like the vinegar of HANNIBAL, will make a way through frozen Alps; it is the open sesame of our profession. When he is satisfied with the beautiful proportions of the interior, its vast and varied dimensions, the intricate and astounding action of its machinery, obeying laws of a singular stability, whose very conflict produces harmony under the government of secondary laws—if there be anything secondary in nature!—when he is satisfied (and such are not satisfied until informed), he will be led to his ultimate object, to take his last lessons from the poor and suffering, the fevered and the phrenzied, from the JOBS and LAZARUSES—into the poorest houses and prisons, and here in these magazines of misery and contagion, these Babels of disease and sin, he must not only take up his abode, but following the example of his Divine Master, he must love to dwell *there*;—*this is Pathology*. When such an one re-enters the world he is a physician; his vast labours have not only taught him how little he knows, but that he knows this little well. Conscious of this virtue, he feels no necessity of trumpeting his professional acquirements abroad, but with becoming modesty and true dignity, which constitute genuine professional pride, he leaves this to the good sense of his fellow citizens to discover." In this fiftieth year of the General Medical Council it is well that we members of the medical profession should be reminded of these modest and high-souled words spoken by one of our kin across the seas. The stress of modern life, of competition, and the struggle for daily bread are only too prone to beget a spirit of "pushfulness" and of each man for himself, which spirit may lead to anarchy and a lowering of ideals. If, then, we have more knowledge than our fathers, let us use it no less well than they did—such as they had.

◆

Weather Forecasts.

ALTHOUGH the uncertainty of the weather is a matter of daily experience there are meteorologists who devote their energies to the task of predicting it and in a fair proportion of cases their anticipations are justified by the event. Some of these forecasts are made for short periods of only a few days in advance by the comparison of numerous barometric observations telegraphed to a central station, whilst others extending over long periods of many months are based on inferences drawn from arbitrary cycles which are presumed to present certain features of recurrence. Medical men might well be interested in both forecasts alike, but as a matter of fact it is generally the short prophecy which has the greater significance for them, as possibly influencing their daily work, and it is the short prophecy dealing with very local conditions which is so frequently misleading.

A number of questions bearing on this subject were discussed at the Royal United Service Institution in Whitehall on Nov. 18th, when Colonel H. E. RAWSON, C.B., R.E., read a paper entitled "A New Principle in Weather Forecasting and its Importance in Naval and Military Operations." Commencing with an allusion to the lack of interest in forecasting shown by the higher authorities of the services, he proceeded to explain the seven principal weather types—namely, anticyclone, wedge, cyclone, V-depression, secondary cyclone, col, and straight isobars. All these terms, it may be here remarked, have reference to the curvature and distribution of the isobars or lines of equal barometric pressure as plotted on a weather chart. He then showed lantern pictures of the earth's surface on Mercator's projection exhibiting areas of high pressure and low pressure during the months of January and July. In the former map (i.e., during winter in the northern hemisphere) there was round the globe in the northern hemisphere a belt of high pressure or so-called permanent anticyclones, which might be subdivided into the Siberian, the Atlantic, the North American, and the Pacific systems; whereas in the southern hemisphere the belt was not continuous but there were three systems of permanent anticyclones lying over the Pacific, the Atlantic, and the Indian oceans. In the map for July (i.e., during winter in the southern hemisphere) there was a very different pressure-distribution. The Siberian and North American systems of high pressure in January were now replaced by areas of low pressure, whereas in the southern hemisphere the anticyclonic belt was now continuous and action-centres (centres of maximum pressure) were found over the land in South America, South Africa, and Australia, as well as over the oceans. The action-centre which lay off the coast of Australia in January had now disappeared.

In 1898 it was pointed out by Colonel RAWSON that when the main or permanent systems ceased to be found in their January or July positions they did not dissipate or become "reversed" as was commonly supposed, but they moved away to reappear over another locality at no great distance from the previous one. Such movements were not continuous but could be described as progressive in character, and, generally speaking, they were in one direction in the early months of the year and in the opposite direction in the later months. In setting forth his views as to the seasonal movements of the belts of high pressure Colonel RAWSON took his illustrations chiefly from the anticyclonic belt of the southern hemisphere, the phenomena of which have been recorded in a large number of isobaric charts from the year 1855 onwards. Not only was each system found further south in summer than in winter, which was the natural consequence of the migration of the belt as a whole, but several boroughs in which the deceased persons had previously resided. During the five weeks ending Oct. 31st the deaths of 5659 persons belonging to London were registered, equal to an annual rate of 12·3 per 1000; in the three preceding months the rates had been 10·3, 12·9, and 12·8 per 1000. The rates of mortality in the several boroughs ranged last month from 8·8 in Hampstead, 9·2 in Lewisham, 9·4 in the City of Westminster, 9·6 in Woolwich, 9·8 in Paddington, and 10·3 in Wandsworth, to 14·8 in Southwark, 15·8 in Bethnal Green and in Stepney, 16·2 in Shoreditch, 18·8 in Finsbury, and 19·6 in Bermondsey. The 5659 deaths from all causes included 586 which were referred to the principal infectious diseases; of these, 63 resulted from measles, 46 from scarlet fever, 53 from diphtheria, 34 from whooping-cough, 37 from enteric fever, and 353 from diarrhœa, but not any from small-pox, from typhus fever, or from ill-defined pyrexia. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Westminster, Hampstead, St. Pancras, Holborn, and Camberwell; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Bermondsey, and Lewisham. The 63 fatal cases of measles showed a decline of 18 from the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Chelsea, St. Marylebone, Finsbury, Bethnal Green, Stepney, and Bermondsey. The 46 deaths from scarlet fever were 20 fewer than the corrected average; the greatest proportional mortality from this disease was recorded in Kensington, Hammersmith, Bethnal Green, Stepney, Poplar, and Lewisham. The 53 fatal cases of diphtheria were 15 below the average for the corresponding period of the five preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, Chelsea, Islington, Finsbury, Hackney, Shoreditch, and Bethnal Green. The 34 deaths from whooping-cough were equal to only one-half of the corrected average number; the highest death-rates last month from this disease were recorded in Kensington, Chelsea, Finsbury, Shoreditch, and Deptford. The 37 fatal cases of enteric fever were 11 below the corrected average number; of these 37 deaths, five belonged to Bermondsey, four to Islington, and three each to Finsbury, Shoreditch, and Camberwell. The 353 deaths from diarrhœa were eight above the average number in the corresponding period of the five preceding years; the greatest proportional mortality from this disease occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, Bermondsey, Deptford, and Lewisham. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 10 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 124 per 1000. No death at this age occurred in the City of London; among the boroughs the lowest rates of infant mortality were recorded in Westminster, St. Marylebone, Hampstead, Stoke Newington, Lambeth, and Woolwich; and the highest rates in Paddington, Kensington, Hammersmith, Shoreditch, Bermondsey, and Greenwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Staff-Surgeons have been promoted to the rank of Fleet-Surgeon in His Majesty's Fleet, viz.:—Percival Marshall May, Christopher Louis White Bunton, Frederick Davidson Lumley, Edward Thomas Meagher, Henry Edward Tomlinson, Arthur Sydney Gordon Bell (dated Nov. 15th, 1908).

The following appointments are notified:—*Fleet-Surgeons*: E. A. Shaw to the *Queen*, on recommissioning; P. V. Jackson to the *Lord Nelson*, on recommissioning; and G. T. Broatch for R.N. Hospital, Yarmouth. *Staff-Surgeons*: S. H. Facey to the *Actæon*, temporarily; G. Gibson to the *Sapphire*; P. K. Nix to the *Cornwall*; and J. Mowab to the *Triumph*, on recommissioning. Surgeons: S. Bradbury to the *Queen*, on recommissioning; E. L. Atkinson lent to Haslar Hospital for special duties, temporarily; A. T. Rivers to the *Lord Nelson*, on recommissioning; H. Cooper to the *Vivid*, additional for Pembroke Dockyard; P. B. Egan to the *Pembroke*, additional, for disposal; H. G. T. Major to the *Spanker*, on recommissioning; P. M. Rivaz to the *Vivid*, additional, for disposal, and to the *Triumph*; and F. M. V. Smith to the *Vivid*. Fleet Paymaster: C. F. Petch to the *Triumph*, on recommissioning.

RESERVE OF OFFICERS.

The undermentioned officers, from the late Royal Army Medical Corps (Militia), having assented to be transferred, are appointed officers of the Reserve of Officers, with effect from Sept. 20th, 1908, retaining the rank and seniority which they held in the Militia:—Captains: Herbert E. Dalby, Samuel T. Beggs, Lieutenant Daniel V. M. Adams.

Militia.—The undermentioned officers, having assented to be transferred, are appointed officers of the Special Reserve of Officers from the dates stated, retaining the rank and seniority which they held while in the Militia:—From the late Royal Army Medical Corps (Militia) (dated Sept. 20th, 1908):—Majors: Harold E. Mortis and William K. Steele. Captains: Jonathan Clerke, John H. P. Graham, Ernest U. Bartholomew, Honorary Major William V. Sinclair, Stuart G. McAllum, James C. Furness, Samuel M. Sloan, and Frederick E. Bissell. Lieutenants: James C. McCarroll, Denis Murphy, Robert A. O'Donovan, Robert J. Stirling, and Wilson Ranson.

The undermentioned officers resign their commissions (dated Sept. 20th, 1908): Captain Hewett J. L. Bullen, Lieutenant Herbert H. B. Cunningham, and Lieutenant Patrick J. Carroll.

TERRITORIAL FORCE.

Yeomanry.

North Somerset: Surgeon-Lieutenant John Empson, from the North Somerset Imperial Yeomanry, to be Surgeon-Lieutenant, with precedence as in the Imperial Yeomanry (dated April 1st, 1908).

Honourable Artillery Company.

Infantry: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Walter Culver James, from the Honourable Artillery Company of London, to be Surgeon-Lieutenant-Colonel, with the honorary rank of Surgeon-Colonel, with precedence as in the Honourable Artillery Company of London (dated April 1st, 1908).

Royal Field Artillery.

2nd East Anglian Brigade: Surgeon-Captain George Alexander Troup, from the 1st Essex Royal Garrison Artillery (Volunteers), to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 3rd East Anglian (Howitzer) Brigade: Surgeon-Lieutenant Richard Wilson Mullock. from the 1st Norfolk Royal Garrison Artillery (Volunteers), to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). Bedfordshire: Surgeon-Captain Henry Skelding, from the Bedfordshire Imperial Yeomanry, to be Surgeon-Captain, with precedence as in the Imperial Yeomanry (dated April 1st, 1908). Essex: Surgeon-Lieutenant Charles Gordon Roberts, from the Essex Imperial Yeomanry, to be Surgeon-Lieutenant, with precedence as in the Imperial Yeomanry (dated April 1st, 1908).

Royal Garrison Artillery.

Essex and Suffolk: Surgeon-Captain Charles Forsyth, from the 1st Essex Royal Garrison Artillery (Volunteers), to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

Infantry.

5th Battalion, The Devonshire Regiment: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel William Henry Webb, from the 5th (The Hay Tor) Volunteer Battalion, to be Surgeon-Lieutenant-Colonel, with the honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Major Ernest Paul Alphonse Mariette, from the 2nd (Prince of Wales's) Volunteer Battalion, to be Surgeon-Major, with precedence as in the Volunteer Force (to be supernumerary) (dated April 1st, 1908). Surgeon-Lieutenant Walter Chapman, from the 5th (The Hay Tor) Volunteer Battalion, to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). The Hertfordshire Battalion, The Bedfordshire Regiment: Surgeon-Lieutenant John Alfred Kite, from the 1st (Hertfordshire) Volunteer of the subject but on a knowledge of a part of its nomenclature. It may be urged that the nomenclature is a part of the subject; that is true, but it is surely the least important part. Examiners should always discriminate between a knowledge of names and a knowledge of things. The two are very commonly confused in the teaching of elementary science. A third fault to be found in examination papers is the insertion of questions which need for their answer a knowledge of very recent researches. It is not very difficult for an examiner to keep *au courant* with the most recent advances, but it is too much to expect that a candidate should know all about some recent investigations or methods which have not yet appeared in any English text-book. Some examiners are specially prone to err in this direction.

It is, however, in the *vivâ voce* examination that the difference between good and bad examiners shows itself most clearly. Some men are born good examiners; they have a natural aptitude for the work but training also counts for much. We may parody BEN JONSON'S line and say "a good examiner is made as well as born." A good examiner improves as the years go by, and even a bad examiner may not be so bad at the end of his term of office as he was at the beginning. As a rule, an examiner gets his first work in examining while he is acting as a demonstrator and his knowledge of the work steadily increases with practice. The faults usually manifested by the examiner in a *vivâ voce* examination are these. An unskilled examiner is inclined to have an exaggerated idea of the knowledge which a candidate should possess but time usually cures that. But he should always bear in mind that what appears simple and obvious to him may be obscure and difficult to a candidate. He must also remember that the average candidate is more or less nervous. There are a few candidates who are unaffected by the severest examinational ordeal but the average candidate is in an uncomfortable frame of mind. It may be said that it is lack of knowledge that makes a candidate nervous; but it is not so necessarily, though doubtless the knowledge of the existence of numerous holes in his armour may tend to daunt the candidate, but even apart from this the mere fact of being examined has a very disturbing effect. This nervousness tends to drive all his knowledge from the candidate's mind. A good examiner will endeavour by simple and easy questions to set a candidate at ease. It is said that the late Sir GEORGE HUMPHRY, when he was examining in anatomy and he saw that the candidate was nervous, would always ask the candidate the structures passing behind the internal malleolus. There is probably no medical student who could not answer this question by the time that his anatomy examination arrives, especially as a well-known mnemonic exists to assist the memory. When the candidate finds that he has answered correctly he regains confidence and his memory returns to him. In this way a good examiner is enabled to estimate fairly rapidly whether the candidate has a good knowledge of his subject or not. It has been well said that examiners are divisible into those who try to find out what a candidate knows and those who try to find out what a candidate does not know. The distinction is very real. A good examiner endeavours to find a part of the subject which the candidate knows; if his first questions do not meet with accurate replies he changes the subject and ultimately he finds some portion with which the student is familiar. The bad examiner acts in an exactly opposite way. If the candidate appears to know the subject first started he leaves it immediately and tries another until he finds one about which the candidate knows little and at that subject he remains fixed until the appalling ignorance of the candidate is manifest. With the former examiner the candidate will give of his best, poor though that best may be; with an examiner of the latter kind the candidate never does himself justice. He does not receive credit for the knowledge which he really does possess. A man may fail at a *vivâ voce* examination with one examiner but pass with another, and yet the standard of the second may be as high as that of the first. Even the tone of voice used by the examiner or the mode of asking the questions may make a great difference to the candidate. Many have pleasant recollections of long-past *vivâ voce* examinations where a sympathetic and careful examiner drew their knowledge from them. Some examiners endeavour to hide from the student any expression of approval or disapproval and some even endeavour to lead a candidate along a wrong path. This is hardly justifiable, and, indeed, we think a candidate has a certain amount of right to know that he has answered correctly. It is useless to attempt to disguise the fact that there are bad examiners. Everyone will agree that there are lecturers who are quite unsuited to be lecturers, though they may be learned physicians or skilful surgeons. In the same way even eminent members of the profession may be quite unsuited to be examiners. Examinations are by no means perfect and though as a whole the results are reasonable, yet lecturers and "coaches" know well the uncertainty of examinations and that the race is not always to the swift.

Can anything be done to do away with the evils to which we have referred? First, as to papers. There should undoubtedly be supervision. In some examining bodies the examiners in different subjects criticise each other's papers and in others a special board is appointed the duty of which it is to see that only suitable questions are set. Some method of supervision is essential and the supervisors, whoever they may be, should veto not only questions which they are sure are unsuitable but also any which are in the very least doubtful. As to the *vivâ voce* examination, every candidate should have two examiners at the same time, so that there may be an opportunity for a candidate to retrieve his position if his unfortunate answers have not been due merely to want of knowledge. There is much to be said for the open examination where at the *vivâ voce* examination any member of the University may be present to listen to the questions and answers. It might, it is true, in some cases tend to increase the nervousness of the candidate but it would at least tend to check the faults of some examiners. But we can imagine some irate examiner exclaiming, "Have candidates no faults?" Indeed, they have many and great but these do not form our subject to-day. Candidates are often very trying to an examiner who is endeavouring to do his best by them, and their ignorance is sometimes wonderful, but it is of examiners that we have written to-day. We have endeavoured to show that some of the

VEGETARIANISM AND PHYSIQUE.

To the Editor of THE LANCET.

SIR,—I have read with great interest your annotation on the above subject.[1] I am in complete agreement with its main contention that "vegetarianism is a fallacy," and I would add, often a dangerous fallacy. In upwards of a quarter of a century of dietetic experience I have seen many whose well-intentioned but ignorant endeavours after the impossible have ended in their own destruction. I also agree that the amount of proteid recommended by Chittenden will not be found sufficient if watched over a longer period and with wider experience. I believe, however, that part of the difficulty of the natives of Bengal is poverty; they could take more proteid and would be stronger if they could get it. With the natives of Western Europe the difficulty is of another kind. They have become accustomed to the use of proteid in very concentrated forms—e.g., meat, fish, game, eggs—and are now unable to take enough when it is presented in the more diffused forms.

There are several ways out of this difficulty, but the vegetarians, who in my experience have seriously injured themselves, have for one reason or another not made use of any of them. If they are to remain true vegetarians they practically must take nuts, yet, though numbers in various countries live to a large extent on nuts, those who have been 30 or 40 years on flesh foods have so modified their digestion and injured their digestive organs that nut digestion may be practically impossible. Healthy children and young adults, on the other hand, can digest most nuts, so that for them true vegetarianism is possible. The other way out of their difficulty is to add animal foods, such as milk or cheese (the most concentrated proteid food we have), to make up the necessary albumins. This is done in other parts to a much larger extent than in Western Europe, possibly because the meat-eating habit has here to some extent driven out other albuminous foods.

It is the purin-free dietists who have added these more concentrated foods in sufficient quantity who have furnished the remarkable records of strength and endurance discussed by Professor Irving Fisher,[2] Professor P. Fauvel,[3] and others, records which may be said to have established the practical superiority of a fleshless diet when sufficient proteid is taken. Vegetarianism has been a great thorn in my side in advocating, as I do, a physiological and purin-free diet (vegetarianism is neither of these), because those who have seen the unfortunate results of vegetarian ignorance have not kept in mind the important physiological points in regard to which I differ so completely from them; for "the mixture of those things by speech which by nature are divided is the mother of all error."

I am, Sir, yours faithfully,
ALEXANDER HAIG.
Brook-street, W., Nov. 21st, 1908.

A SERUM TREATMENT OF CARCINOMA IN MICE.

To the Editor of THE LANCET.

SIR,—Dr. Blair Bell says in his letter, published in THE LANCET of Nov. 21st:—"Mainly my complaint was, then, that no reference at all was made by Mr. Walker to the work of others on similar lines ...... and I carefully mentioned in my remarks that there *was* a difference in technique in some of the work, but that there was no *essential* difference." At the meeting of the Liverpool Medical Institution on Oct. 22nd, in reply to Dr. Blair Bell's criticisms, I stated that though familiar with the work of Dr. Borrel, I was unaware of his having done anything similar to my experiments. I dealt chiefly with Dr. Borrel because Dr. Bell represented his work as being most like to my own. As Dr. Bell has thus on two occasions declined to accept my well-considered statement, I took the only step that, under the conditions chosen b him, would make an absolutely conclusive answer possible. I wrote to Dr. Borrel, inclosing a copy of my paper, a asking him whether he had ever done any experiments simil to those I described. Obviously I cannot write to everyo who has worked with mouse cancer. In Dr. Borrel's rep to me, dated from the Pasteur Institute, Nov. 12th, 1908, says: "I have never treated mice by inoculating them wi a serum obtained with the testicles of mice. ...... I tried produce immunity in mice by injecting them with crushe testes; the results were published by Bridré, (they wer negative. But (I have done) nothing resembling the exper ments you describe." I may point out that, as well as th experiments with testis serum, those with tumour seru were described in detail in the paper I sent to Dr. Borrel.

In the *résumé* of his remarks upon my paper, furnished b himself to the secretary of the institution, Dr. Bell empha sised the words "testis serum." He also quoted Dr. Borr as having done experiments similar to the rest of my exper ments. Dr. Bell also quoted Dr. Borrel and others as havin produced immunisation in mice by injecting the cells various tissues, "and hand-in-hand, of course, with this i producing curative effects on these animal growths." Beside the contradiction of this assertion, made by Dr. Borre himself, I may say that the statement contained in m former letter that the sera that had been found to produc immunisation "possessed no curative effect whatever upo already existing tumours," was taken from a general *résum* of all the work done upon this point, written by Dr. Borr late in 1907.

I have nothing further to say than that there is no mo foundation in fact for the other statements made by D Bell than there is in the case of his statement that Dr. Borr had worked with "testis serum." (The inverted commas a Dr. Bell's.) I inclose Dr. Borrel's letter of Nov. 12th i order that you may see that my statements are correct.

I am, Sir, yours faithfully,
CHARLES WALKER.
Cancer Research Laboratory, University of Liverpool,
Nov. 23rd, 1908.

⁂ We have received Dr. Borrel's letter to Mr. Walk containing the sentences quoted.—ED. L.

EARLY RECOGNITION OF MALIGNANT DISEASE.

To the Editor of THE LANCET.

SIR,—A great deal has been written in recent year regarding the importance of thorough removal of malignan disease when at all possible. The adoption of this has le to greatly improved results and less frequent recurrence Can our profession not do a little more in order to encourag patients to consult their medical advisers at an earlier dat than they do? It is a delicate matter to speak of suc things to patients, but some general information might b given so that instead of women consulting their medica men when a cancer of the breast is far advanced and giving pain they would do so whenever they noticed anything abnormal. The cancer would be operated on when i was entirely local and the results would be very muc better. Until the cause of cancer is discovered I am satisfied that some decided effort must be made in the direction of earlier recognition. A great deal is being done with regard to tuberculosis and a large amount of instruction has been given to the public on the subject. Similar efforts ought to be made in connexion with malignant disease.

I am, Sir, yours faithfully,
J. CRAWFORD RENTON.
Glasgow, Nov. 21st, 1908.

THE CAUSE AND PREVENTION OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—Will you kindly extend to me the courtesy of your columns so that I may draw attention to the fact that Mr. F. Coleman's criticism is not only justified but that it has been anticipated, inasmuch as a reviewer in the *Dental Surgeon* drew attention to the point he raises in his letter in THE LANCET of Nov. 21st so long ago as 1905. The notice in question, which was otherwise entirely favourable, to be responsible for the admission of patients, and no advertisements of the institute were to be issued without his knowledge. In spite of this, during the plaintiff's absence on a holiday a pamphlet was issued advertising the treatment with testimonials as to its effects printed in it. Evidence was given by Dr. A. G. Bateman, general secretary of the Medical Defence Union, to the effect that the document was such that had it been proved to be issued with the plaintiff's knowledge it would have led to his appearance before the General Medical Council with the probability of the removal of his name from the Register. Responsibility for it was afterwards acknowledged by Mr. Barton-Wright, the managing director of the defendant company, who admitted in the witness-box that his remuneration as such was dependent on the dividends earned and that finding the receipts falling off he had issued the pamphlet complained of at his own expense. The same witness alleged complaints by patients with regard to their treatment by the plaintiff. The jury found as stated above, and the plaintiff is entitled to congratulation upon the result of the trial. That the advertisements should have been issued in defiance of such an agreement as his will serve as a warning to medical men entering upon contracts with commercial companies providing treatment of a medical character. The result of the action shows that clauses can be introduced of sufficient stringency to protect the reputation of the medical man and that a court of law will recognise and enforce them. But we feel that Dr. Neale ran some risk in associating himself with the Bartitsu Light Cure Institute, Limited.

ASCITES IN ENTERIC FEVER.

IT might be thought that the long list of complications of a disease which is so common and has been so much studied as enteric fever was exhaustive. But in the *American Journal of the Medical Sciences* for November Professor McPhedran of Toronto has called attention to a complication which, so far, appears to have escaped observation—ascites. During the past three years no fewer than six cases in which this complication was present have come under his observation. In all the effusion occurred during the illness and persisted for from 10 to 14 days. It disappeared in all but one during convalescence. In all the cases the illness was severe, but in only one were there hæmorrhages or symptoms of peritonitis. In the most marked case the patient was a married woman, aged 33 years, who had two children. She was admitted to hospital very ill, with a temperature of 104° F. After a few days rose spots, enlarged spleen, leucopenia, and the Widal reaction showed that the disease was enteric fever. The abdomen was never distended but remained relaxed throughout. The attack proved severe and protracted. In the third week both flanks were full in the dorsal position and the note on light percussion was dull to the nipple line, but on deeper percussion was amphoric. Fluctuation was easily demonstrated. When the patient was turned on her side the upper flank became concave and tympanitic, and the dependent one full and rounded with fluctuation and well-marked dulness to the parasternal line. That these signs were not due to fluid in the colon was shown by the fact that a copious enema had no effect on them. A purgative was then given; it acted freely without affecting the signs. The quantity of fluid diminished twice and then increased again. Finally, it gradually disappeared, leaving the flanks retracted when the temperature became normal. In a second case a labourer, aged 22 years, was admitted into hospital on Sept. 22nd, 1905. He had enteric fever in the preceding year, but the symptoms of the disease were now marked—the usual temperature, diarrhœa, moderate abdominal distension, rash on chest and abdomen, enlarged spleen, leucopenia, and the Widal reaction. The illness was protracted, there being apparently a series of relapses. Signs of ascites were apparent on Oct. 23rd and were marked until Dec. 6th, when they gradually diminished and disappeared in 10 days. The abdomen was flaccid throughout the illness and was not tender on deep palpation. In one case the ocular tuberculin reaction was negative and in another it was positive and the effusion appeared to be due to tuberculous peritonitis. In at least four of the six cases the ascites appeared to be due to the enteric fever, but its immediate cause cannot be stated. Professor McPhedran suggests that mesenteric glands may have been greatly enlarged, causing slight irritation of the peritoneum and effusion. Another hypothesis is that the effusion was due to toxæmia. It may be remembered that even in cirrhosis of the liver the ascites, which was supposed to be due to obstruction of the portal system, is by modern pathologists, attributed, in part at least, to irritation of the peritoneum by alcohol or other toxic substance. We may point out that peritonitis without perforation is a rare but recognised complication of enteric fever. An interesting example was recorded in our columns by Mr. C. G. Watson.[1] Dieulafoy has explained this condition as due to infection of the peritoneum by the typhoid bacillus in the same manner as the pleura (in typhoid pleurisy) or bones (in typhoid periostitis) may become infected. Possibly the cases of ascites reported by Professor McPhedran are of a similar nature, differing only in the fact that the peritonitis is of such mild form as not to give rise to the usual symptoms of pain and so forth. Perhaps also the prostrated condition of the patient, which Professor McPhedran says was present in all his cases, rendered the patient somewhat insensitive to pain. But whatever the explanation his observations are remarkable and will probably lead to records of other cases of this previously undescribed complication of enteric fever.

ANCESTRAL BEER-DRINKING.

"WOE unto him that giveth his neighbour drink, that puttest thy bottle to him, and makest him drunken also." The passage, a denunciation of cynical conviviality, is part of "the burden which Habakkuk the prophet did see." Our Bible-reading ancestors seem to have paid no attention to this and similar passages, for, as lately as the beginning of the nineteenth century, hosts were not supposed to have treated their male guests properly till they had made them drunk. In ordinary life, when not entertaining guests, the men of the seventeenth and eighteenth centuries seem to have been prodigious drinkers. Working men, now so denounced for an ancestral tendency towards the consumption of beer, seem positively to have gloried in their cups. Benjamin Franklin, between 1757 and 1775, describes the daily beer-drinking of the London printers. These skilled workmen, who required to keep a clear head at all times in the performance of their excellent work, took each man a pint of beer before breakfast, a pint with that meal, a pint during the morning, a pint at early dinner, a pint at 6, and a pint when work ended. "This makes three quarts," as the late Sir Walter Besant remarked in his delightful "London," "without counting any beer that might be taken in the evening." This beer was, of course, mostly "small beer," of which the modern representative is apparently "four-half." Sir Walter Besant also describes a notable family of the time of Charles II., whose accounts he had studied. They lived some 15 miles from London in a seven-roomed house, and the household consisted of a young married couple, a brother, "Mr. Arthur," four maids and a baby, and a gardener out of doors. They seem to have been persons of which the certificate could in case of necessity be produced without there being any general violation of secrecy as to prove how a person has voted at an election, which I believe can always be done in this country though the voting is by ballot.

G. P.

QUESTIONS IN EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—In the recent examination in midwifery at the University of London for the degrees of M.B. and B.S. the second question was, "What is meant by the term 'middle pain'? Discuss the various theories as to its causation." The term "middle pain" is not employed in the vast majority of the text-books on gynæcology. It is not given in the large 24-volume encyclopædia medica, and therefore it is evidently not an expression in common use. I think I am correct in saying that seven-eighths of the candidates had never heard it before. It is obvious that examiners should exercise more care in setting questions; they should avoid any peculiar and local terms which are not included in the ordinary text-books. If questions such as these be set it must be entirely a matter of chance whether any individual candidate can answer. The University of London has often been blamed for setting foolish questions, and certainly it appears to me that more supervision should be exercised as to the questions set.

I am, Sir, yours faithfully,
Nov. 24th, 1908. M.D., F.R.C.S.

⁂ It should certainly not have been assumed by any examiner or group of examiners that the students were familiar with the term. The question was to our mind an unjustifiable one. We deal with some aspects of the matter in a leading article this week.—ED. L.

THE CHOLERA EPIDEMIC IN RUSSIA AND PERSIA.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

DURING the last two months, as all the world knows, cholera has spread very widely throughout Russia. Your columns have already contained some account, from other sources, of the course of the outbreak; but the following summary of the statistics of the epidemic (as officially communicated to the Constantinople Board of Health) may be useful. I may note that the early records of the outbreak were given at length in my letter which appeared in THE LANCET of Sept. 5th (p. 765); but it would be impossible, if for reasons of space alone, to continue the record with the same degree of detail. It will be recalled that the disease was first recognised in Astrakhan on July 8th (21st). The subsequent returns were as follows:—

		Cases.	Deaths.
From July 8th (21st)	to July 19th (Aug. 1st)	98	... 47
" " 20th (Aug. 2nd)	" " 26th (" 8th)	262	... 125
" " 25th (" 7th)	" Aug. 1st (14th)	538	... 270
" Aug. 1st (14th)	" " 8th (21st)	1145	... 517
" " 8th (21st)	" " 15th (28th)	1199	... 573
" " 16th (29th)	" " 23rd (Sept. 5th)	1241	... 568
" " 23rd (Sept. 5th)	" " 30th (" 12th)	2296	... 1026
" " 30th (" 12th)	" Sept. 4th (17th)	3392	... 1377
" Sept. 5th (18th)	" " 12th (25th)	4393	... 2034
" " 13th (26th)	" " 20th (Oct. 3rd)	3251	... 1571
" " 20th (Oct. 3rd)	" " 27th (" 10th)	2210	... 1082
" " 28th (" 11th)	" Oct. 4th (17th)	1571	... 819
" Oct. 5th (18th)	" " 12th (25th)	1048	... 552

The above dates and figures are quoted from the official returns. It will be noted that the periods are not always exactly of a week's duration and that in one instance (the third in the table) the dates overlap. Nevertheless, the above statistics may be looked upon as approximately correct; they furnish a total of 22,644 cases and 10,561 deaths since the beginning of the epidemic down to Oct. 25th (New Style). These cases and deaths have been distributed over the following governments or provinces: In the valley of the Volga, the governments of Astrakhan, Saratof, Samara, Simbirsk, Kazan, Nijni Novgorod, Kostroma, Yaroslavl, and Tver; in the south the Don Cossack Territory, the governments of Ekaterinoslav, Kherson, the Taurida, Kharkof, Poltava, and Kief; in the centre, the governments of Voronezh, Tambof, Riazan, Tula, Orel, Vladimir, Smolensk, Moscow, Penza, Tchernigof, Kaluga, Kursk, and Minsk; in the north-east, in the governments of Viatka, Perm, Ufa, and Orenburg; in the northerly governments of Vologda, Olonetz, and Archangel; in the north-west, in those of St. Petersburg, Novgorod, Pskof, Vitebsk, Vilna, Livonia, and Esthonia; and, finally, in the Polish governments of Warsaw. All the above are in European Russia. In Asiatic Russia the presence of the disease has been recorded in the Transcaspian province, in the territories of Uralsk, Akmolinsk, and Semipalatinsk, and in the Syr-Daria and Ferghana provinces of Russian Turkestan; in the Terek and Kuban territories of the Caucascus, and in the governments of Tiflis, Baku, Elizavetpol, and Kutais in Transcaucasia. Finally, in Siberia, the governments of Tomsk, Yeniseisk, and Irkutsk were all invaded by the infection.

The epidemic is now declining in all parts of the Russian empire and in the south it has almost disappeared. Its degree of severity has varied greatly in different parts of the country. It has been most intense in the governments along the valley of the Volga, in the Don Cossack Territory, and in St. Petersburg, in European Russia. The returns from Asiatic Russia have been less complete, but there is already evidence that the disease has been fairly active in the northern Caucasus, in the Uralsk Territory, and perhaps elsewhere. This year's epidemic has been more severe than last year's. It may be recalled that in 1907 the disease broke out on the Volga in July and spread to a great part of both European and Asiatic Russia; but from the beginning of that outbreak to Dec. 10th (New Style), when the epidemic was practically extinct, the total cases recorded numbered only 11,934 and the deaths 5706[1]; whereas, as just shown, in the present year these figures have already been nearly doubled and the epidemic is still far from complete extinction. The area covered by the two outbreaks has been very much the same; in each year the Volga Valley has suffered most and in each year the infection has travelled to most parts of European Russia and to some of the principal provinces of Central Asia and Siberia. Last year, however, St. Petersburg escaped, whereas this year it has suffered severely; in the present year also the disease has spread to the extreme north in Europe, invading the Olonetz, Vologda, and Archangel governments. This was not the case last year. The epidemic in St. Petersburg has, from all accounts, been a decidedly severe one. No official figures for the total numbers of cases and deaths there are as yet available, but there is reason to believe that they will prove to be as high as in the great epidemic of 1892. In that year there were 4391 cases with 1357 deaths in St. Petersburg.

Last week news was received that cholera had appeared in Tabriz and its neighbourhood. The extent of the outbreak there is not known. In the present disturbed state of that city and of the province of Azerbaijan the appearance of cholera is a most unfortunate occurrence and one that may well lead to disastrous consequences.

The subsidence of cholera in southern Russia just at the beginning of this year's Moslem pilgrimage is, on the other hand, a matter for congratulation. During the past week the first steamer carrying pilgrims from Russian ports has passed down the Bosphorus. It may be recalled that last year the Constantinople Board of Health formulated a unanimous "vœu" that Russia would apply to the pilgrims before departure the measures of medical inspection, disinfection, and, if possible, a preliminary quarantine, such as have been for years past applied by the Indian authorities to their pilgrims. This year the Russian Government has acceeded to this wish; a large lazaret has been put up at Odessa; the pilgrims all start from that port; and they are subjected to a medical inspection, the disinfection of their clothes and effects, and a preliminary observation in the lazaret of five days' duration. Pilgrim ships that have undergone these measures are now allowed to pass the Bosphorus and Dardanelles *en contumace* and proceed directly to the Abu-Saad lazaret, near Jeddah, where they undergo a final disinfection. Any pilgrim ship, on the other hand, that has not undergone the measures before departure is sent to the lazaret of Sinope on the Black Sea, where the same

EXTRAORDINARY FRAUDS IN RUSSIAN PHARMACY.

AN extraordinary series of frauds which have been perpetrated over a great part of Russia has been brought to light. According to the *Torg. Prom. Gazeta* certain German firms, manufacturers of proprietary articles, observed a marked decline in the demand for their goods from Russia, although their agents observed an increasing quantity of goods bearing their principals' labels in the pharmacies. A police inquiry was set on foot and certain suspected individuals were traced to Odessa where a large manufactory with offices and distributing organisation was discovered. The guilty parties were arrested. A long series of "pseudo-German" preparations made up of the most inexpensive substitutes were packed in irreproachable bottles labelled in perfect imitation of the original firms' articles. The business done was enormous, amounting, it is said, to £200,000 for the Odessa organisation alone. Some of the firms whose goods have been supplanted by the imitations are household names in Germany. The German Union for the Protection of German Patents is claiming damages on behalf of the sufferers to the extent of £50,000. That this is only part of a widespread system is evident from the statement of the *Yuzhny Pharmatzeft* ("The Southern Pharmacist") to the effect that an inquiry has revealed that over 58 per cent. of pharmacies and pharmaceutical stores sell "falsified" products, though not in the same gross form as was discovered in Odessa where the disinfectant xeroform was "made" from bricks, sirolin from water, sugar, and colour, and thiocol, tannalbin, and somatose from mixtures of soap, lime, and dyes. Various cheap salts, including table salt, were substituted for such well-known products as quinine, phenacetin, and pyramidon.

THE THERAPEUTIC APPLICATIONS OF SODIUM PERSULPHATE AND OTHER OXIDISING SUBSTANCES.

WITHIN the last few years considerable use has been made of various highly oxygenated products, particularly the perborates, peroxides, and persulphates. Their value depends upon the liberation of nascent oxygen or hydrogen peroxide when brought into contact with moisture. Sodium perborate liberates about 10 per cent. of active oxygen, sodium persulphate about 13 per cent., and calcium peroxide about 11 per cent. Of these substances, all of which are non-proprietary, sodium persulphate is probably the least known. It is of interest, therefore, to make reference to *Merck's Report* for November where its properties and therapeutic uses are described. In the presence of water sodium persulphate decomposes into sodium sulphate, sulphuric acid, and active oxygen, the reaction being facilitated by elevated temperatures and the presence of oxidisable matter. If it be desired to avoid the production of free sulphuric acid the persulphate may first be mixed with one-and-a-quarter times its weight of sodium carbonate. In the form of an aqueous solution it is useful in strengths ranging from 3 to 10 per cent. as a gargle and as a dressing. At first only superficial wounds and lacerations were treated, with the result that the wounds all healed within a day. It was then applied to ulcers, infected wounds, incised furuncles, and, finally, to all wounds requiring a moist dressing. It has also been employed for disinfecting the skin prior to operations and on the wounds during operations; for example, in the extirpation of small cysts and the excision of foreign bodies. In such cases the wounds healed rapidly, small, non-infected ones generally in one or two days, while purulent ones soon granulated and closed. In the treatment of small ulcers sodium persulphate is mixed with an equal weight of powdered talc and used in the form of a fine dusting powder. It has generally been found that a 5 per cent. solution is sufficiently strong to give good results in purulent wounds and a 3 per cent. solution in simple wounds. Sodium persulphate has been tried in gonorrhœa without producing any other effect than a lessening of the discharge. The only side effects that have been noticed were a slight reddening and inflammation of the skin in children with a very sensitive skin. It cannot be used to disinfect metallic instruments as it rapidly attacks them. Sodium persulphate possesses advantages over most other antiseptic substances when used in the form of bandages or other dressings from the fact that it is readily soluble, odourless, does not stain the skin, and is non-toxic in the quantities that are usually employed.

THE SOCIETY OF APOTHECARIES.

THE Master and Wardens of the Society of Apothecaries entertained a large company at dinner at the hall of the Society on Tuesday, Nov. 24th, the occasion being known as the Lord Mayor's Day dinner. The chair was occupied by the Master, Mr. F. Gordon Brown, who was supported by the Senior Warden, Mr. R. Bligh Wall, and the Junior Warden, Mr. A. T. Norton. The guests included, amongst others, the Lord Mayor, Sir Richard Douglas Powell, Sir James Reid, Sir John Tweedy, and Sir Francis Laking. The loyal toasts finished, the Senior Warden rose to propose that of "The Lord Mayor, Sheriffs, and Corporation of the City of London." In acknowledging this toast, the Lord Mayor referred to the public health work of the Corporation and to the activities of the port sanitary officials in fighting disease and death. He welcomed the presence there of so many distinguished members of the medical profession and particularly the representatives of the great governing bodies. The Junior Warden in proposing the toast of "The Colleges of Physicians and Surgeons" referred to the question of a combination of the examining corporations of London which could grant the joint qualifications of physician and surgeon. Sir R. Douglas Powell, replying for the Royal College of Physicians of London, said that it had taken a great number of years to organise the medical profession but the question of an equalised qualification was still a difficulty. Referring to the dinner, he congratulated the society on its compatibles. Sir John Tweedy, who in the absence of Mr. Henry Morris, the President, replied for the Royal College of Surgeons of England, apologised for dealing with the question of qualification, but he was prompted to do so by the remarks which fell from the Junior Warden. He referred to the rapidly increasing number of universities growing up like mushrooms all over the country, a growth which made it more difficult to bring the medical degree to a universal standard. He thought it desirable that the educational centres should combine in the matter of conferring a degree which should be the evidence of a uniform test. During the evening the honorary freedom of the Society of Apothecaries was presented by the Master to Sir Francis Laking who, in acknowledging the honour done to him, compared the work of the general practitioner of many years ago with that of to-day. He thought that students, in addition to their clinical practice at the hospital, should spend some time with a general practitioner so that they might get an insight into the common of the Congress so as to proclaim these opinions to the world.

Sunlight and Ventilation.

If laws are necessary to secure good sanitation in factories and workshops these are no less required in regard to the construction of private dwellings and especially of tenement dwellings. Dr. CHARLES DENISON (Denver, Colorado) qualified tuberculosis as being practically a "house disease due to deficient air renewal and sunlight," and then asked what law of ventilation could be devised and enforced to secure its prevention. He proposed a compromise between Parkes's rule of 3000 cubic feet per person within a room and De Chaumont's renewal rule of two-thirds of a square foot space inlet and outlet per person. This compromise is 2000 cubic feet of space per person with entire renewal of the air once every hour, but Dr. Denison was careful to add that this would be insufficient if not aided by sunlight. He urged that "we must take into consideration the influence of the sun, the source of atmospheric electricity, in fitting the air for respiration."

Dr. SAMUEL BERNHEIM (Paris) defined tuberculosis as "a disease of darkness," and explained that in France, where families lived in apartments, though the occupants of the lower flats were wealthier and paid higher rents they were more susceptible to tuberculosis than the dwellers in the upper and cheaper flats, because the latter apartments, though similar in every other respect, received more light and sunshine. Even cleanliness could not compensate for the lack of light, and very clean and tidy people living in dark tenements were the ready victims of the disease.

The newest pronouncement on this subject was by M. AUGUSTIN REY (Paris), who pointed out that in the planning of towns the angle formed by the direction of the street with the meridian had hitherto been overlooked. With houses of equal height the width of the streets should vary with each change of frontage. A street running due east to west must be 50 per cent. wider than a street running due north to south. The other streets should vary in width according to their distance from these two extreme limits. But this rule again would be modified according to the degree of latitude of the town to be built, the object in all cases being that the lowest inhabited floor should be able to receive the direct rays of sunshine for one and a half hours on the shortest day of the year. At Baltimore M. Rey subsequently gave a lecture with numerous lantern slide illustrations explaining his theories. He demonstrated how unhealthy houses were built and how they might be reconstructed so as to respond to the laws of health.

Tuberculosis and the Hours of Labour.

The Hon. DAVID J. BREWER, of the Supreme Court of the United States, delivered an address in Section V. on what the law in America might, and might not, do in regard to the prevention of disease. He said that an employer can be compelled by the State to protect those whom he employs. He must provide them with fire-escapes, with ventilation, and whatever else is necessary so as to prevent their health being unfavourably affected. The employer must see that the employee does not continue to work if the work causes him injury. On the other hand, if the employment is not at all unhealthy then the American Declaration of Independence gives the inalienable right to liberty in the pursuit of happiness. Therefore, continued Judge Brewer, a man may work 12 hours a days if it does not injure his health. There is not a judge in our courts, he added, who does not work ten or more hours a day.

Dr. WELCH (Baltimore) replied that these were beautiful theories which were not put into practice. Obviously if this theory was applied the hours of labour could be restricted in a very large number of occupations, and this not merely in regard to the work of women and children but also of adult males.

Dr. H. P. FAVILL (Chicago) argued that what labour demands and what capital refuses have nothing to do with the thing. The intervention of the law depended on the national necessity of such intervention. It was only necessary to realise the power of health as a means of production to make health the first consideration. Of course, crowding produced conditions favouring the spread of tuberculosis, and they had to create a new moral conception as to the necessity of air-supply. The State should declare what are the standard conditions of healthy labour. Fresh air during working hours was the first requirement in fighting tuberculosis.

Dr. LEONARD (Ohio) entered an earnest protest against Judge Brewer's conception that a man might work as long as he liked if it did not injure his health. Man had other duties to perform than earning a livelihood. He had his duties towards his family and his duties of citizenship. The speaker then described the case of a railway servant, a model workman, who accepted all the overtime work he could get so as to add to the income and comfort of his family. The consequence was that he had no time to exercise any moral control over his children, and one of his sons was sentenced to a term of confinement in the reformatory to which Dr. Leonard is attached. This boy had lost his birthright; his father was a stranger to him, otherwise he might have become a good citizen. Most of the reformatory and refuge boys had no father. From the moral as much as from the health point of view such excessive work as divorced parents from their children might well be prohibited.

Here, then, a great question was put forward. To what extent and in what circumstances would the limitation of the hours of labour tend to reduce the prevalence of tuberculosis? Again we have to lament that there is no record of a vote indicating what was the opinion of the Section that had discussed at some length this important and practical question.

Tuberculosis and Milk and Meat.

Undoubtedly the most striking feature of the Washington Congress was the extraordinary prominence given to the question of bovine tuberculosis. There is in America such an enormous business in the rearing of cattle that a special Government department has been created to deal with it, the Department of Animal Industry. At the Congress a special section, Section VII., was devoted to the question of Tuberculosis in Animals and its Relations to Man. The great joint meeting of this section with Section I. (Pathology and Bacteriology), at which the majority of the members of the other sections also assisted, has already been fully described.

In Section VII. Dr. J. G. RUTHERFORD, who holds a high post under the Dominion Government of Canada, introduced a useful discussion as to what could be done to protect cattle. Formerly it used to be urged that the rich would best protect themselves from the spread of disease by promoting good sanitation among the poor. We have now got far beyond this, for the whole of the work of Section VII. was devoted to protecting mankind from disease by promoting good sanitation and better health among cattle. But Dr. Rutherford explained how great were the difficulties. To kill all cattle that showed a reaction to the tuberculin test was not practical. Killing and disinfecting did not suffice and no compensation the State could give would meet the case where choice cattle were concerned. Also cattle that have been tested several times fail to react to further tests, though they may have become tuberculous in the interval. Then a great outlay and much labour might be rendered futile by the dishonesty of a farmer and a veterinary surgeon. Antipyrine could be mixed with sugar and meal and is licked up by the animal without anything occurring to create suspicion. So the thermometer readings do not prove much and there are lunches and other diversions to keep the veterinary surgeon away when the temperature rises. Even with very close and constant examinations mistakes are made. It would be more practical to kill young animals and to devise methods of segregation and of treatment for the older animals. Some sort of legal control was absolutely necessary and all milk from cows that reacted to the tuberculin test should be pasteurised. Dr. Rutherford thought that one or more *clinical cases occurring* in a herd should suffice to justify Government interference together with the compulsory preparation of a report and he quoted THE LANCET as endorsing this opinion. He did not think that any encouraging results had been obtained by prophylactic inoculation, but while he was a pessimist in regard to the new methods he was absolutely sure and confident in regard to the beneficent effects resulting from the careful ventilation of stables. Stockmen are breeding bacilli faster by want of ventilation than could be stamped out with tuberculin. Open-air treatment for cattle was the most promising preventive. Nature provided the necessary protection; the remedy was to get closer to nature.

of trick, real bullets not being used. In this instance the assistant, a man named Lee, who is said to have performed with "Madame Clementine" for some time, stood with the ball balanced on a little wire stand above his head. Two shots were fired at him, both of which, by pre-arrangement, were misses; at the third discharge, which was intended to hit the mark, Lee fell to the ground. The audience thought this was a part of the performance but a stage hand seeing something was wrong lowered the curtain. It was then found that Lee had been hit fairly between the eyes with a bullet, and he was at once conveyed to a hospital where he died. It is difficult to understand why the regulations do not prevent entirely this class of performance. A shooting exhibition, which may be undoubtedly an attractive and skilful performance, can surely be arranged without endangering a human life. In any case, if the management desired to provide its patrons with a sensational show having the appearance of being dangerous it should have insisted on the use of wax bullets or some similar device. We are quite unable to understand the attitude of the manager of the music-hall if he said, as was reported in the *Daily News*, "I never imagined that this was what we call a 'straight turn.' That is to say, I thought there was some trick about it and that real bullets were not used." If the performer had been firing real bullets night after night surely the management ought to have been aware of the fact, so that warning might have been given to scene-shifters and others who might be standing behind the scenes to beware of stray shots. It is high time that it should be made illegal for such performances to be given. For many years now acrobats and wire-walkers have been forbidden to perform in public high up in the air unless a broad net be stretched beneath them and regulations should be framed to protect other people from risking their lives to gratify the more savage elements of the popular craving for amusement. There are many feats of strength and grace and dexterity performed by tumblers and jugglers which have a certain risk attached to them but to which no exception can be taken, for although a slip might lead to a nasty accident, yet they are on a different plane altogether from the performances which are advertised justly as "sensational," and which depend upon that quality for their popularity. The kind of laxity which connives at possible manslaughter as an incident in public entertainments deserves the unmeasured condemnation of all thoughtful persons.

THE Bradshaw Lecture of the Royal College of Surgeons of England will be delivered in the threatre of the College by Sir W. Watson Cheyne, Bart., Vice-President, on Friday, Dec. 4th, at 5 P.M. The subject of the lecture will be "The Treatment of Wounds." Fellows and Members of the College are invited to attend. Students and others, who are not Fellows or Members of the College, will be admitted on presentation of their private visiting cards.

AT the meeting of the Life Assurance Medical Officers' Association, to be held at 20, Hanover-square, London, W., on Wednesday, Dec. 2nd, at 8.30 P.M., the discussion on Sir Thomas Oliver's paper on Some Insurance Problems arising out of Recent Industrial Legislation, adjourned on Nov. 4th, will be resumed. Members of the medical profession are invited to attend the meeting.

MR. John Fairbank, F.R.C.S.E., has been appointed surgeon dentist to T.R.H. Prince and Princess Christian of Schleswig-Holstein.

MOTORING NOTES.

THE OLYMPIA MOTOR EXHIBITION.—II.

BY O. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

THE Olympia show during the time of the "press" view and subsequently I discovered to be quite two different places; on my second visit I found more cars but less room or opportunity to see them in, the "public" had arrived and, judging from the vast crowds, it was everybody who wanted to see and to find out about the motor-car. I truly felt quite sorry for the really kind young gentlemen in charge of the exhibits but I likewise rather admired them, they replied to the queries of their possible clients with much patience and some of the questions were really enough to annoy a saint. While listening to some of these amusing conversations I managed to get a look at a few cars I neglected on my earlier inspection and among a good many the following should certainly receive the attention of the medical man in search of an automobile.

Messrs. S. F. Edge have always been known as most successful makers of racing and large touring cars; this year they have added to their manufacture a two-cylinder, 10-h.p. car which they seem fairly certain about, as it is sold with a guarantee extending over three years from the date of delivery. I do not know of any other firm that gives such an undertaking with their machines. The engine is the water-cooled two-cylinder (cast together) Napier, with inlet and exhaust valves operated off one cam shaft and interchangeable. The carburettor is provided with an arrangement so as to flood without raising the bonnet; those who have had the bother of taking lamps off to open the bonnet to get at the carburettor on starting will, I know, appreciate this little improvement. Ignition is by high-tension magneto and arranged so that the magneto can be rapidly detached and replaced. Transmission is by cardan shaft to a live axle; three speeds forward and a reverse are provided, the drive on the top speed being direct. The propeller shaft has universal joints at each end. The change-gear is on the gate-change system. The clutch is of the metal to metal type and runs in oil and gives a smooth and gentle engagement. The water circulation is by a gear-driven pump; another gear-driven pump also forces oil to the engine and clutch. Semi-elliptical springs insure easy riding and the tyres are of a good size, 810 × 90. A similar car with a four-cylinder 15-h.p. engine is also shown.

The 12-h.p. four-cylinder Talbot is also likely to be a popular car. The engines, 80 × 90, are cast in pairs. Ignition is by high-tension magneto, driven by a transverse spindle in front of the motor, which spindle also drives the water-pump. Alternative battery ignition is also fitted. A leather-faced cone clutch transmits the power to the four-speed forward and reverse gear-box, and so on by cardan shaft to the live axle. A tube surrounds the cardan shaft and acts as a torque rod.

An American car that has attained great favour in this country is the Cadillac 10-h.p. single cylinder two-seated runabout. A copper water-jacket is fitted round the cylinder. Transmission is by sun and planet gear, which are always in mesh. Lubrication is by a pump lubricator of the Dubrille type, driven by a belt off the hub of the fly-wheel. As the cylinder has a bore of 5 inches, starting it with the ignition advanced might have serious consequences, so a safety device is fitted; when the spark is advanced the slide obstructs the entrance to the crank, so making it impossible to start the motor until the spark lever is moved to its normal position. The ignition is by coil and accumulator or dry cell, and a double insulated spark-plug is an exclusive feature of the car, though of course any other plug can be employed. A chain conveys the power from the planetary gear box to the live axle. A chain may make a little noise, but there is this advantage over the rigid or ought-to-be-rigid propeller shaft type: it does not matter with a chain if the back axle and the gear box are not quite true with one another; with bevel and cardan shaft if the two bevels are not perfectly true with one another then worries and expense result. Standardisation absolute and accurate is one of the leading claims urged by this company on behalf of their cars, and they certainly proved their point last March, when seems a pity that an institution which in other respects is so admirably designed should be without this very necessary adjunct. The absence of proper means of isolating infected patients must add considerably to the difficulties of administration and a very grave responsibility would rest upon the committee if the present means at the disposal of the medical superintendent for coping with an outbreak of infectious disease proved inadequate.

The Wiltshire County Council and the Medical Inspection of School Children.

At a meeting of the Wilts county council held on Nov. 18th under the presidency of Lord Bath, considerable discussion took place in reference to the medical inspection of school children. Hitherto the work has been done by the district medical officers under the supervision of the medical officer of health of the county, but at this meeting a scheme was submitted by the finance committee recommending the appointment of two whole-time medical officers at salaries of £250 each with travelling expenses of £125 each. Other recommendations were made and the total estimated cost of the scheme was £1055. Much opposition was manifested to these suggestions and an amendment was moved that the matter should be sent back to the general education committee, with an expression of opinion that the present system of inspection should be continued. This amendment was eventually carried by 22 votes to 14.

Exeter "Carnival."

As a result of the recent "carnival" which was held at Exeter the sum of £165 has been handed over to local charities. £80 were awarded to the Royal Devon and Exeter Hospital, the remainder being divided amongst the smaller institutions.

Nov. 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medico-Psychological Association.

THE half-yearly meeting of the Scottish division of this association was held in the hall of the Royal College of Physicians, Edinburgh, on Nov. 20th. There was a large attendance of members and Dr. T. S. Clouston occupied the chair. After the chairman had referred in fitting terms to the death of Dr. J. Cameron of Lochgilphead, and the loss thereby to the association, the superannuation allowances committee reported that Sir John Jardine had stated his intention of bringing in next session the Bill drafted by the division, and the intention was expressed to approach all Scottish Members of Parliament that they may assist in the promotion of the measure. Mr. Hugh F. Watson, senior assistant medical officer, Ayr District Asylum; Dr. W. Tuach-Mackenzie, medical superintendent, Dundee Royal Asylum; Dr. W. McWalter, medical officer, H.M. Convict Prison, Peterhead; and Mr. George Dunlop Robertson, medical officer, Smithston Asylum, Greenock, were unanimously admitted members of the association. Dr. W. Ford Robertson and Dr. R. Dods Brown communicated a paper on the Bacteriology of the Cerebro-spinal Fluid in General Paralysis of the Insane and gave a microscopical demonstration. An animated and lengthy discussion followed the reading of the paper, which was taken part in by Dr. Lewis C. Bruce, Dr. H. C. Marr, Dr. G. M. Robertson, Dr. G. D. McRae, Dr. J. H. Macdonald, Mr. W. Muirhead, and the chairman. The speakers were in general agreement with Dr. Ford Robertson, except Dr. Marr who said that during the course of three years' research in the cerebro-spinal fluid he had examined 53 cases of general paralysis and had come to the conclusion that in ordinary general paralysis there was no microbic organism present and that the disease was probably not of microbic origin.

Royal Medical Society of Edinburgh.

At a meeting of this society held on Nov. 20th Dr. T. B. Johnston read a paper on Jaundice. He especially discussed the two theories of jaundice: (1) the obstructive; and (2) the toxæmic, and reviewed at length the arguments which have been brought forward in support of each. Dr. A. E. Turnbull read the interesting case of a boy, aged 14 years, who suffered from Carcinoma of the Large Intestine, and who subsequently developed symptoms which led to the diagnosis of meningism. Dr. Turnbull discussed the differential diagnosis between this and true meningitis. Mr. Buist showed a large number of metallic and other articles which had been swallowed by a man in a fit of despondency. Mr. Gunson showed an interesting case of Klumpke's paralysis.

The Causes of Crime.

At a meeting last week of the Royal Philosophical Society of Glasgow Mr. James Devon, the medical officer of Duke-street Prison, lectured on the causes of crime. Mr. Devon has come to be recognised as one of the most capable criminologists in the country and his views were received with much interest. At the commencement attention was drawn to the statement usually present in official reports to the effect that the great majority of those in prison were there through drink. He protested against the practice of singling out one from among our vices and attaching to it the blame of all our social evils. The most troublesome and dangerous criminal was the professional, and no more than other professional persons did he go to business the worse for drink. He thought the facts showed that drink puts a man into a condition in which he was more liable to commit a crime or police offence than when sober; that while drinking was common to all in all parts of the country police offences and crimes occurred mainly in closely populated districts; that the amount of crime and police offences in Scotland was not dependent on the amount of drinking alone, but was mainly dependent on indulgence in drink under certain conditions of urban life; and that the major portion and the most serious kind of crimes against property were not due to drink. Nor could it be said that the amount of crime in Scotland was in relation to poverty alone. In some parts of the Western Highlands and Islands the poverty was appalling and yet there was an entire absence of crime. All experience showed that crime occurred not in proportion to the number of the population but to its density. In particular, overcrowding not only bred disease but it tended to destroy decency, and if they were to consider the circumstances that make some kinds of vice and crime so easy and even natural to many attention would have to be given to this aspect of city life.

Prevention of Consumption in Glasgow.

The annual meeting of the Glasgow branch of the National Association for the Prevention of Consumption took place last week. At Bellefield Sanatorium, which is under the auspices of the society, 98 patients were admitted and 95 were discharged during the year, making a total of 368 patients treated since the opening four years ago. Of the 95 discharged 27 had the disease arrested, 38 were much improved, 20 were improved, nine were not improved, while one had died. During the year a new pavilion has been erected to accommodate 22 additional patients. A special appeal was made for funds, as the ordinary income last year was less than the expenditure by £480.

Nov 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin University Biological Association: Opening Address on History of Irish Medicine.

THE most interesting in many of its features of the public professional events of the past week was the opening meeting of the thirty-fourth session of the Dublin University Biological Association, which was held on Nov. 19th in the debating hall of the Graduates' Memorial Building, Trinity College. There was a large and highly representative audience, many of the most prominent senior members of the medical and other professions being present as well as a crowded congregation of students. After the distribution of medals to the various successful competitors by the outgoing President (Dr. R. J. Rowlette), Dr. T. Gillman Moorhead delivered the opening address which dealt with the subject of the "History of Medicine in Ireland." The lecturer began, very literally indeed, with the beginning—i.e., in prehistoric antiquity—and the best testimony to his skill and success was furnished by the fact that an unusually long paper was listened to throughout with attention by all his audience. The Irish medicine man of the pre-Christian centuries, the introduction of Christianity by St. Patrick of trick, real bullets not being used. In this instance the assistant, a man named Lee, who is said to have performed with "Madame Clementine" for some time, stood with the ball balanced on a little wire stand above his head. Two shots were fired at him, both of which, by pre-arrangement, were misses; at the third discharge, which was intended to hit the mark, Lee fell to the ground. The audience thought this was a part of the performance but a stage hand seeing something was wrong lowered the curtain. It was then found that Lee had been hit fairly between the eyes with a bullet, and he was at once conveyed to a hospital where he died. It is difficult to understand why the regulations do not prevent entirely this class of performance. A shooting exhibition, which may be undoubtedly an attractive and skilful performance, can surely be arranged without endangering a human life. In any case, if the management desired to provide its patrons with a sensational show having the appearance of being dangerous it should have insisted on the use of wax bullets or some similar device. We are quite unable to understand the attitude of the manager of the music-hall if he said, as was reported in the *Daily News*, "I never imagined that this was what we call a 'straight turn.' That is to say, I thought there was some trick about it and that real bullets were not used." If the performer had been firing real bullets night after night surely the management ought to have been aware of the fact, so that warning might have been given to scene-shifters and others who might be standing behind the scenes to beware of stray shots. It is high time that it should be made illegal for such performances to be given. For many years now acrobats and wire-walkers have been forbidden to perform in public high up in the air unless a broad net be stretched beneath them and regulations should be framed to protect other people from risking their lives to gratify the more savage elements of the popular craving for amusement. There are many feats of strength and grace and dexterity performed by tumblers and jugglers which have a certain risk attached to them but to which no exception can be taken, for although a slip might lead to a nasty accident, yet they are on a different plane altogether from the performances which are advertised justly as "sensational," and which depend upon that quality for their popularity. The kind of laxity which connives at possible manslaughter as an incident in public entertainments deserves the unmeasured condemnation of all thoughtful persons.

THE Bradshaw Lecture of the Royal College of Surgeons of England will be delivered in the threatre of the College by Sir W. Watson Cheyne, Bart., Vice-President, on Friday, Dec. 4th, at 5 P.M. The subject of the lecture will be "The Treatment of Wounds." Fellows and Members of the College are invited to attend. Students and others, who are not Fellows or Members of the College, will be admitted on presentation of their private visiting cards.

AT the meeting of the Life Assurance Medical Officers' Association, to be held at 20, Hanover-square, London, W., on Wednesday, Dec. 2nd, at 8.30 P.M., the discussion on Sir Thomas Oliver's paper on Some Insurance Problems arising out of Recent Industrial Legislation, adjourned on Nov. 4th, will be resumed. Members of the medical profession are invited to attend the meeting.

MR. John Fairbank, F.R.C.S.E., has been appointed surgeon dentist to T.R.H. Prince and Princess Christian of Schleswig-Holstein.

MOTORING NOTES.

THE OLYMPIA MOTOR EXHIBITION.—II.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

THE Olympia show during the time of the "press" view and subsequently I discovered to be quite two different places; on my second visit I found more cars but less room or opportunity to see them in, the "public" had arrived and, judging from the vast crowds, it was everybody who wanted to see and to find out about the motor-car. I truly felt quite sorry for the really kind young gentlemen in charge of the exhibits but I likewise rather admired them, they replied to the queries of their possible clients with much patience and some of the questions were really enough to annoy a saint. While listening to some of these amusing conversations I managed to get a look at a few cars I neglected on my earlier inspection and among a good many the following should certainly receive the attention of the medical man in search of an automobile.

Messrs. S. F. Edge have always been known as most successful makers of racing and large touring cars; this year they have added to their manufacture a two-cylinder, 10-h.p. car which they seem fairly certain about, as it is sold with a guarantee extending over three years from the date of delivery. I do not know of any other firm that gives such an undertaking with their machines. The engine is the water-cooled two-cylinder (cast together) Napier, with inlet and exhaust valves operated off one cam shaft and interchangeable. The carburettor is provided with an arrangement so as to flood without raising the bonnet; those who have had the bother of taking lamps off to open the bonnet to get at the carburettor on starting will, I know, appreciate this little improvement. Ignition is by high-tension magneto and arranged so that the magneto can be rapidly detached and replaced. Transmission is by cardan shaft to a live axle; three speeds forward and a reverse are provided, the drive on the top speed being direct. The propeller shaft has universal joints at each end. The change-gear is on the gate-change system. The clutch is of the metal to metal type and runs in oil and gives a smooth and gentle engagement. The water circulation is by a gear-driven pump; another gear-driven pump also forces oil to the engine and clutch. Semi-elliptical springs insure easy riding and the tyres are of a good size, 810 × 90. A similar car with a four-cylinder 15-h.p. engine is also shown.

The 12-h.p. four-cylinder Talbot is also likely to be a popular car. The engines, 80 × 90, are cast in pairs. Ignition is by high-tension magneto, driven by a transverse spindle in front of the motor, which spindle also drives the water-pump. Alternative battery ignition is also fitted. A leather-faced cone clutch transmits the power to the four-speed forward and reverse gear-box, and so on by cardan shaft to the live axle. A tube surrounds the cardan shaft and acts as a torque rod.

An American car that has attained great favour in this country is the Cadillac 10-h.p. single cylinder two-seated runabout. A copper water-jacket is fitted round the cylinder. Transmission is by sun and planet gear, which are always in mesh. Lubrication is by a pump lubricator of the Dubrille type, driven by a belt off the hub of the fly-wheel. As the cylinder has a bore of 5 inches, starting it with the ignition advanced might have serious consequences, so a safety device is fitted; when the spark is advanced the slide obstructs the entrance to the crank, so making it impossible to start the motor until the spark lever is moved to its normal position. The ignition is by coil and accumulator or dry cell, and a double insulated spark-plug is an exclusive feature of the car, though of course any other plug can be employed. A chain conveys the power from the planetary gear box to the live axle. A chain may make a little noise, but there is this advantage over the rigid or ought-to-be-rigid propeller shaft type: it does not matter with a chain if the back axle and the gear box are not quite true with one another; with bevel and cardan shaft if the two bevels are not perfectly true with one another then worries and expense result. Standardisation absolute and accurate is one of the leading claims urged by this company on behalf of their cars, and they certainly proved their point last March, when

Member of the Academy of Medicine in the room of Professor Terrier, deceased. At the meeting held on the 24th the President announced the death of M. Hamy, professor at the museum and a member of the Academy. He also announced the death of Professor Joffroy who had died that morning.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Medical Society.

THE winter session of the Berlin Medical Society opened on Oct. 28th, Professor Senator being in the chair. Professor Meyer reported the case of a man, 57 years of age, in whom a set of artificial teeth had slipped into the trachea as low down as the bifurcation without producing any immediate symptoms, so that the dentist in whose practice the accident had happened believed that the teeth had entered the stomach. A febrile bronchitis occurring after 24 hours was ascribed to a chill, and as the state did not improve the patient was sent to the seaside. The bronchitis became much worse there and the patient suffered from dyspnœa. He was seen five weeks after the accident by Professor Meyer who by bronchoscopy found the foreign body in the bifurcation of the trachea. He removed it by a forceps. Professor Oppenheim reported the case of a woman, 37 years of age, who for more than a year suffered from headaches, difficulty in articulation, giddiness, vomiting, and bradycardia. On examination he found sensory and amnestic aphasia and agraphia, bilateral optic neuritis, paresis of the right facial nerve, and tenderness on percussion of the left frontal region. He diagnosed a growth of the left temporal lobe and recommended an operation which was performed by Professor Krause. A growth of the size of an apple proved to be present in the very place indicated, issuing from the arachnoidal membrane and growing into the cerebral substance. The growth was enucleated and the patient felt better when a fortnight afterwards a paresis of the right arm and of the face supervened. The paresis disappeared sooner than usual, but eight months later, with severe general symptoms, vomiting and unconsciousness, a total right paresis occurred. Professor Krause trephined over the place of the first operation and again found a growth of almost the same size, which had evidently grown from a small piece of the first tumour left behind. After enucleation the patient made a quick recovery. She was shown to the society; there was no paresis but the articulation was still impaired. Professor Krause gave a detailed account of the operation which he performed in two sittings. Dr. Zuelzer read a paper on the "Hormone" of the Peristaltic Movement. He said that it had been discovered by recent biological research that certain organs produced substances which were conveyed by the circulation to other remote organs and produced in them certain alterations. He alluded to the researches of Professor E. H. Starling who found that the embryo produced a substance which stimulated the development of the mamma during pregnancy. This substance, termed by him a "hormone," when injected into virgin rabbits produced a swelling of the mammæ. The same was the case with secretin, another "hormone," a substance found by Dr. F. Bayliss and Professor Starling in the mucous membrane of the duodenum and the intravenous injection of which produced a secretion of the pancreas. Dr. Zuelzer had found by recent researches that the peristaltic movement of the intestines was also caused by a "hormone" which he termed the "peristaltic hormone" and which he separated from the mucous membrane of the stomach. It was essential for the production of the substance that the stomach of the animal should be in an active state of digestion, as it is not found in empty stomachs. When peristaltic hormone was injected into the vein of a rabbit a strong peristaltic movement from the duodenum to the rectum was visible within a few seconds and the excrement in the gut passed through to the anus. As to the method of obtaining the peristaltic hormone he explained that it must be extracted from the mucous membrance of the stomach by a solution of kitchen salt or diluted muriatic acid and the albumin then removed by alcohol. The stomach of rabbits, pigs, and horses and the rennet-bag in cattle contained the hormone. It might also be obtained from the upper parts of the duodenum, but in less quantity and of milder action. Dr. Zuelzer said that Professor Starling had compared the action of hormones with that of alkaloids and that the peristaltic hormone acted like physostigmin on peristaltic movements.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Health of the Pope.

"IL Papa sta molto bene" was the reassuring, if guarded, announcement issued yesterday evening by his body-physician, Dr. Petacci, in answer to many inquiries. All the same, the physical state of His Holiness, particularly on Nov. 19th, more than justified the solicitude with which the "archiatro" was approached for authoritative information In the forenoon of that day he was giving audience to one of the many companies of pilgrims who had come to congratulate him on his sacerdotal jubilee—this one being the "Pellegrinaggio Ligure-Piemontese" (the pilgrimage from Liguria and Piedmont). In reply to their spokesman's address, he had not uttered many words when suddenly his voice failed and he had to request the Archbishop of Vercelli to convey his acknowledgments as briefly as possible. In anticipation of such a breakdown Dr. Petacci had urged the Pope to suspend all the receptions already arranged, but the august patient could not be persuaded to deny himself to the Italian pilgrims whose turn was still to come. Now, however, he has seen the wisdom of his physician's advice; he has not ventured outside his apartment; and one of the most important of the pilgrimages, that from Spain, will have to be received later. The outside world hardly realises the immense strain imposed these many days past on the Pope's energies or the adverse conditions under which it has been kept up. Pilgrimage after pilgrimage had to be received in audience and their special circumstances—often highly controversial, as in the case of the "Pellegrinaggio Francese"—duly considered and commented on in the pontifical reply. Add to this that in the transit from his private rooms to the reception hall he had to pass through draughty corridors of various temperatures, and after exerting his voice in a hall in which the air was charged, not to say vitiated, by the respiration of successive crowds, he had to return mentally fatigued and physically relaxed through the same corridors to the same apartments—in itself a considerable journey. What wonder if, in the humid atmosphere of these last days of torrential downpour, His Holiness has contracted a "raffreddore" (chill), accompanied with aphonia and even a recrudescence of the arthritic pains from which, after any excessive call on his energies, he is prone to suffer? Nor has he been the only one in the Vatican itself to fall a victim to the malaise seemingly inseparable from high mental and physical tension prolonged through a series of days among pilgrims thronging the Apostolic palace. The major-duomo, Monsignor Bisleti, is now on the sick list from causes similar to those affecting the Pope, and his duties have for the nonce to be discharged by Monsignor Sanz de Samper. Before him, the Austrian ambassador to the Holy See, Count Szeczen, was attacked with measles, and now the Envoy of the Emperor Francis Joseph, charged with a special mandate on occasion of the Pope's jubilee, is "down" with scarlet fever In truth, pilgrimages in all countries, especially those organised with a religious object, are often the importers of infective or contagious disease in the places to which they are destined. Not only measles and scarlet fever have often been contracted in the crowds consisting of all classes which, on days of special ceremonial, fill St. Peter's, but, as many an English-speaking consultant practising in Rome can testify, variola itself, and that of the grave type known to Italian physicians as "nera" (black), has often been contracted by compatriots with disastrous, if not fatal, consequences. Personal cleanliness, in Latin countries especially, is not a universal characteristic; nay, the Englishman's devotion to the morning bath has but recently been adopted, and only by slow gradations, on the continent, even among the higher orders. Let one typical illustration suffice, put on record by the *Times* Roman correspondent, just which is not as subject to fatigue as the usual type employed. Personally, I have had three cranks break and the makers have always explained the accident as the result of fatigue and so I welcome a steel which does not get "tired." The rough forged and finished crankshafts shown certainly look as if they would last a lifetime.

From what I gather this show has been a great success not only as regards the number of visitors but also in the direction of "business." Many practitioners seem to have grasped this opportunity to inspect and, what is more, to order a car. The majority have—wisely, I think—stuck to cars built on accepted lines and have left the certainly interesting new developments, such as the two-cycle and slide-valve types, to the man of pleasure. Probably, if he finds them reliable, next year they will more seriously compete with the Otto-cycle engine with mushroom valves. Two-seaters rightly seem to be the favourites with the medical profession, especially when fitted with a Cape-cart hood and a front wind screen. Personally I prefer the mica shield, but apparently glass front screens are the favourite. Small side doors to the body also are popular; they certainly keep the cold from the legs and feet, but a shaped rug answers as well and is less trouble to get into than the bother of opening and shutting a door every time a stop is made to see a patient. As to engines, the single cylinder still appears to hold its own, though the small four-cylinder attracts a good many; the cardan shaft and live axle look as if they are more beloved than the chain drive, still I rather think that the fashion will revert to the latter. Thermo-syphon cooling is undoubtedly increasing, and any way the friction-driven pump has gone. May it never come back! The gear drive answers well, but volumes could be written about the iniquities and worries of the "friction" drive. As to clutches, the leather-faced cone type still holds the field and if springs are inserted under the leather it always engages gently, and in addition anyone can adjust or replace the leather. With the multiple disc it usually means a mechanic or even the makers if aught goes wrong. Still, if clutches are seen to they rarely give trouble. In lubrication the tendency seems to be a reversion to the pump lubricator, driven direct or by a band off the crank or two-to-one shaft, and this is certainly more satisfactory than the one worked by pressure off the exhaust; the pressure pipe is so apt to become choked with carbon deposit, and it is a bother to get the pipe off for cleaning purposes. A great many cars are now fitted with shields underneath, which are an advantage, provided a trap-door is supplied, so that the crank case oil cock can be got at without contortions amid clothes-spoiling surroundings. This is a point I strongly advise seeing to when ordering a car. Carburettors have now reached, I suppose, a stage of perfection, but on some cars they are placed in a rather inaccessible position, and that is another point I should insist on when buying a new machine—namely, that a petrol filter is fitted, and fitted where it can be got at and cleaned, and also that the jet can be quickly removed for cleansing purposes. I came across a man held up on the road recently with a choked jet, and he had to get the exhaust pipes down before he could remove the carburettor and so take out the jet. I prefer jets that can be removed without even taking the carburettor down. The Allen-Liversidge brake, which was described in THE LANCET of Nov. 14th, p. 1463, seems so excellent that when I get my new car I think I shall specify for it to be substituted for the ordinary differential drum brake. The increase in the number as well as in the size of the ball bearings was another improvement noticed at the show.

PLAGUE IN LIVERPOOL: REPORT OF THE MEDICAL OFFICER OF HEALTH.

THE medical officer of health of Liverpool reported to the health committee that on Oct. 23rd the mate of the coal barge *Wesley*, lying in the Trafalgar Dock, who had been ailing for a couple of days, was told by a medical man who saw him to go to hospital. Late in the evening his wife, who lived with him on board, conveyed him to the hospital, which was reached about half-past eight. The man on arrival was found to be dead. The body was removed from the out-patient department to which it had been taken to the mortuary. On Monday, Oct. 26th, a post-mortem examination was made and an inquest held, the house surgeon of the hospital giving evidence to the effect that death was due to natural causes consequent upon acute blood-poisoning. As the house surgeon suspected the case might have been one of typhus fever he communicated at this stage with the medical officer of health who requested Dr. W. Hanna, the medical officer of the port (whose large experience of plague has on former occasions proved so valuable), to see the body and to obtain specimens for cultivation.

Dr. Hanna found indications of the presence of an axillary bubo and he obtained a portion of the tissues for bacteriological examination at the laboratories and a portion was also forwarded to the bacteriologist of the Local Government Board. The coffin in which the body was placed was well filled with carbolic powder and the remains were interred on the next day, the coffin being taken directly from the mortuary to the grave. Meantime, on Oct. 27th, the barge in question was thoroughly disinfected and a rat-catcher was immediately placed on board, but no rats could be found. Furthermore, a survey and a careful inquiry were made along the line of docks in the area which the barge traversed, but no dead rats could be seen or had been observed. Meanwhile, considerably over 100 live rats from the vessels with which the barge had dealings and from the sheds in the neighbourhood were sent to Professor Sir Rubert Boyce for examination and all were found to be healthy The usual proceedings were taken to keep under observation all persons who could be ascertained to have been in contact with the patient or to have had dealings with the barge, some of the probable "contacts" being in Widnes. A cat which had belonged to the patient could not be found and it may be mentioned that the cabin was found to be swarming with fleas. The articles of clothing of the deceased were either destroyed or disinfected, and some of them which had been pawned were recovered from the pawnshop and dealt with in a similar way. The bacterial investigations were pursued with great care both in Liverpool and in London, but no positive results could be obtained by either investigator, owing probably to the delay in taking the material and to the presence of large numbers of other disease-producing organisms, until the afternoon of Nov. 3rd, when positive results were arrived at.

It may be stated here that immediately the mate fell ill a man was taken on board the barge to assist in its navigation, and on Oct. 26th, before the disinfection of the quarters, his wife also went on board. The master of the barge lived at Walton and only went on board during the day. On Nov. 4th, under the terms of the Paris Convention relating to plague, the case was reported by the Local Government Board to the Foreign Office, and at the same time the medical officer informed the Consular body in the city. On the evening of Nov. 5th an announcement was made to the daily press by the Local Government Board. On the morning of Nov. 6th the wife of the man who went on board when the mate fell ill, in conformity with instructions to report herself if any sickness arose, went to the Port Office and stated that her husband had been unwell through the night and that she had been unable to get any medical assistance for him, owing to the barge being remotely placed in the dock. Dr. Hanna at once revisited the barge and the man and his wife were removed forthwith to the hospital at New Ferry, and the barge was again submitted to a further disinfection and the hatchways were closed. The barge remains in this condition now. The usual notifications were given in conformity with the terms of the Paris Convention, and Dr. R. A. Farrar of the Local Government Board visited Liverpool on Nov. 8th and has given very material assistance in investigating the origin of the first case.

With regard to the two patients, the man and his wife, in each case the illness was of a most critical nature, and although the man succumbed to the disease the woman fortunately survived and will in all likelihood recover. The patients were under the care of Dr. Hanna, and he also applied a prophylactic vaccination to the staff. The necessary delay in confirming the nature of the cases, together with Sunday supervening, gave rise to a day's delay in notification to the Consuls. The barge now is in the position in which she was left by the disinfecting staff. Fortunately the men refused to go on board her to discharge her coal, and the owners are perfectly satisfied with the course adopted.

pelvis, had lacerated the pyramids, and weighed 3 ounces; the size was 4 inches by 1½ inches. The third case was that of a man, aged 55 years, who suffered from a swelling in the left lumbar region without any discomfort. A cystic tumour of the kidney was diagnosed and an operation was performed. A large cyst was found replacing the lower half of the kidney and was removed. The upper pole of the organ, together with the ureter, was left behind. The examination of the cyst wall showed it to be one of the very rare instances of cystadenoma of the kidney, whilst the fact that the patient is doing very well now, two years after operation, is also noteworthy, for although there are many people alive and well with only one kidney, there can be very few with one kidney and a half.

Nov. 23rd.

Obituary.

SALVATOR ALOYSIUS PISANI, C.M.G., M.D. MALTA & EDIN., L.R.C.S. EDIN.,

LATE CHIEF GOVERNMENT MEDICAL OFFICER IN MALTA.

Dr. Salvator Pisani, whose death on Oct. 27th has been announced, was an old and prominent inhabitant of the island of Malta, where he was born in 1828 and where, like his father before him, he was for many years the leading medical practitioner. He studied in Malta, where he took the degree of M.D. in 1850, after which he proceeded to Edinburgh, becoming an M.D. of that University three years later. He also took the Licentiateship of the Royal College of Surgeons of Edinburgh. He studied during the next year in Berlin, London, and Paris, and in 1854 he returned to Malta to join his father in practice there. During the Crimean war he proceeded to Scutari to join the hospital of the British troops in which Miss Florence Nightingale was nursing. On returning to Malta he was appointed professor successively of anatomy, midwifery, surgery, and clinical surgery at the University and also surgeon and accoucheur of the Central Civil Hospital. These appointments naturally led to an extensive private practice which he gave up on being appointed chief Government medical officer in Malta, an appointment which gained him the C.M.G. in 1895. He spent the last years of his life in retirement at his residence in Valetta.

THE PROPOSED BRISTOL UNIVERSITY.—A draft of the proposed charter of incorporation of the Bristol University has been deposited in Parliament and now awaits confirmation.

RUSSIAN VIEWS ON INOCULATION AGAINST CHOLERA.—According to the *Novoe Vremya* a council of medical sanitarians has held a meeting at which many authorities were present to discuss the question as to whether it is advisable to inoculate the mass of the population as a prophylactic against cholera. Privat-docent Oleinik held that inoculation could be useful only to the uneducated classes, for the intelligent classes can protect themselves by ordering their lives in a more hygienic manner. The action of serum on the human organism has not yet been determined fully, whilst a great deal depends upon the nature of the serum itself. Private institutions prepare it without any supervision and some medical men declare that even after three inoculations no effect has been observed. Again, sterilised serum is sometimes used, which cannot fail to produce bad results. In future the serum must be carefully inspected. It was decided that each medical man should visit all those whom he had inoculated
…ir homes and report upon their subsequent condition.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE half-yearly session of the General Council of Medical Education and Registration opened at the offices of the Council, 299, Oxford-street, London, W., on Tuesday, Nov. 24th. Sir DONALD MACALISTER, the President, was in the chair.

New Member.

Sir T. CLIFFORD ALLBUTT, K.C.B., introduced to the Council by Dr. NORMAN MOORE, took his seat as representative for the University of Cambridge.

The President's Address.

The PRESIDENT then delivered his address. He said: The Council to-day enters on its second half-century. Fifty years ago, in pursuance of the Medical Act of 1858, it was summoned by the Secretary of State for the Home Department, and meeting in the hall of the Royal College of Physicians, with Dr. Thomas Watson as temporary chairman, elected Sir Benjamin Brodie to be its first President. The Act charged the Council with the duty of creating and maintaining the Medical Register for the information of "persons requiring medical aid." The Register was the instrument devised by the legislature to enable such persons "to distinguish qualified from unqualified practitioners." Thus, by the law of its foundation, the Council's primary purpose was the promotion of a specific public interest of great importance. In constitution and in function it differed from the existing medical faculties and corporations. By its constitution, nine only of its 24 members need be qualified practitioners themselves. The President, the University members, and the Crown members might be laymen. Its function was to safeguard the public by insuring that the Register should be trustworthy. To this end the Council was intrusted with two-fold powers. It had authority to supervise the admission-tests whereby the "qualification" of practitioners was ascertained; it had authority, also, to remove those who, after "qualification," had proved themselves unworthy. From these two powers the manifold activities of the Council, as they are exercised to-day, have slowly but inevitably been developed. Subsequent Acts of Parliament have modified in detail the composition of the Council, or defined more clearly the scope and mode of its action, or imposed upon it additional public duties of various kinds. The decisions of the courts have declared the nature and extent of its jurisdiction and laid down the principles which govern its disciplinary procedure. The enlightened coöperation and criticism of the licensing bodies have enabled it to formulate a standard of "qualification" which is generally accepted not only within the United Kingdom but in many parts of the British dominions beyond the seas. But the root, from which all the rest is but a natural outgrowth, is contained in the brief preamble of the Act of 1858, whose jubilee we commemorate at this meeting. Retrospect is tempting on such an occasion; but in the interest of the Council's time, which in more than one sense is valuable, I propose to resist the temptation to indulge in retrospect from this chair. I had recently the opportunity to trace at some length what appeared to me to be the main lines of the Council's development. My paper has been published in the medical journals and separately, and it is unnecessary that I should now trouble you by repeating its narrative or its comments. But I may be allowed to reiterate my conclusions; they express, as well as I can express it, the outcome of the long and chequered story.

The Medical Council began its life with powers and duties that were indicated rather than defined. It had at first to contend with grave difficulties, internal and external. Like other British institutions, it had to make its way through a tangle of ancient traditions, vested rights, and sacred privileges. It had to "find itself" before it began to be effective. But that it has grown and borne many

…it again?"

A **MEMBER** complained that he had never received a oting card.

When the amendment was put to the meeting it was lost.

Mr. R. **HILLS** moved an amendment that the whole of the rst paragraph should be omitted. It was wrong for the Council to act in opposition to the expressed wish of the Members. The amendment was not seconded and when the original motion was put to the meeting it was carried with ew dissentients.

Dr. W. G. **DICKINSON** introduced the second motion, namely:—

That this meeting is of opinion that women when admitted to the diplomas of the College should have equal rights with men.

He quoted the opinion of counsel taken by the Council as to the admission of women, and he claimed that the Council was relying too much on this opinion. The Members had also taken counsel's opinion, and this had been to the effect that women were admissible under the Charter of the College, for the Charter spoke only of "persons." If this were so, women were not admissible under the enabling Act of 1876. He was under the impression that no other medical body had attempted to make use of the Act of 1876. If women were admissible under the Charter they were not admissible under the Act of 1876, and therefore the Council would find itself in a dilemma, for if women were admissible under the Charter they would have all the rights of the other Fellows and Members.

Dr. A. S. **MORTON**, in seconding the motion, said that if women were admitted they should have equal rights with men. If women accepted the conditions imposed by the Council they would be in a worse position even than the Members.

Mr. **COLLINGWOOD** expressed the opinion that the conferring of diplomas such as suggested would be in opposition to the spirit of the times.

The motion was put to the meeting and was carried by a large majority.

Mr. **COLLINGWOOD** then moved—

That the President and Council of the Royal College of Surgeons be respectfully asked to use their moral influence to obtain some more sufficient title for those who have passed the examinations for the Conjoint Diploma, remembering the importance attached to degrees to the detriment of holders of the said diplomas granted by this ancient corporation in conjunction with the Royal College of Physicians of London.

He claimed that the holders of the Conjoint diploma deserved a degree in medicine. Professor W. Osler and others had said definitely that the examinations of the Conjoint Board were quite as difficult as those of many degree-conferring bodies. It made a great deal of difference in practice. Statistics had shown that the average time taken to obtain the London Conjoint diploma was six and three-quarter years, while only five and a half years were required for Scottish graduates. The two Royal Colleges were in effect a university.

Mr. J. **BRINDLEY JAMES** seconded the motion and pointed out that the College of Physicians refused to allow its Licentiates to use the title of doctor.

Dr. J. B. **FITZGERALD** mentioned that he had passed the examination for the Membership in 1876; it was a decidedly stiff ordeal and fully equal to most other examinations, even in medicine, for the College of Surgeons at that time examined in medicine. He urged that the Members of the College who had passed in medicine should be admitted to a medical degree.

Dr. **RICHARD PARAMORE** was of opinion that the grievance was more imaginary than real. He did not think that the absence of a degree interfered with the power of making a good practice.

A **MEMBER** pointed out that there was a real grievance in the fact that at many hospitals the rules required a degree in the candidates for the staff appointments and would not be satisfied with the Conjoint diploma.

The motion was carried by a great majority.

Mr. H. **ELLIOT-BLAKE** then moved:—

That this meeting is of opinion that the Council of the Royal College of Surgeons, if possible in arrangement with the Royal College of Physicians, should adopt a hood and cap to complete the Conjoint or Fellows' and Members' academicals.

He pointed out that the Royal College of Preceptors and the Royal College of Music each gave a hood to its diplomates and therefore there had been a misapprehension in the decision of the Council not to grant a hood on the plea that "hoods do not appear to be in general use among Colleges of similar standing to the Royal College of Surgeons in England."

The **PRESIDENT** stated that the Council could only reply in the same terms as last year to a resolution which was to the same effect as a resolution of last year. The Council had come to a careful decision in the matter and had stated the grounds on which its decision had been based.

The motion was not seconded and so it was not put.

Dr. **LAWRENCE** then asked permission not to move his motion on the agenda expressing an entire want of confidence in the management of the College affairs and finances by the Council, this action being taken at the request of the Society of Members.

Mr. **HILLS** then asked if the Council would be willing that the Members should be represented on the Council by four Fellows in general practice.

The **PRESIDENT** replied that necessarily he could not reply for the Council but he pointed out that at the last election of members of Council a Fellow of the College in general practice was a candidate and received a large measure of support.

ROYAL SOCIETY OF MEDICINE.

DEBATE ON HEREDITY, WITH SPECIAL REFERENCE TO CANCER, TUBERCULOSIS, AND DISEASE OF THE NERVOUS SYSTEM.—*(Continued from p. 1546.)*

Professor **KARL PEARSON** said that on the present occasion he occupied a third position, which was scarcely recognised by the medical profession on the one hand, nor by the biologist on the other. He was a mathematician or statistician. Most of the cases which had been discussed, and illustrations which had been thrown on the screen required some aid from the mathematician if the results were to be interpreted. Still, the mathematician was liable to make blunders unless he acted with the medical man and the biologist. He sympathised very largely with what Dr. Mercier said about the need for obtaining statistics with regard to normals as well as to abnormals. He (Professor Pearson) had himself compiled in his own way records of 400 families but he did not think that inferences could be drawn until about a thousand cases had been collected. The majority of those were put together by medical men, not necessarily from simple inquiry of patients at hospitals but from knowing the families over a long time. It was very difficult to obtain accurate results from inquiries in a London hospital. His own opinion was that the population in London was decidedly inferior to that met with in the north of England and in Scotland. And the statistics of Dr. Rivers, which were based upon sympathetic acquaintance with the patients, were not subject to the criticism which Dr. Latham passed upon them. All would agree about Dr. Mercier's remarks concerning mutations. His own view was that there was no truth in Mendelism at all. At the last meeting he saw on the screen one or two pedigrees which were supposed to illustrate Mendelism. There was Viall's pedigree which was familiar to most of those present, and recently Dr. Viall's son had carried that down one or two generations further. Diabetes insipidus or polyuria was traced through a non-affected member. Such cases were rare but they very probably existed. Pedigrees of albinism were also shown. He was much interested in that, because he had been busy, in conjunction with Mr. Nettleship, in collecting pedigrees of albinism from all parts of the world. They had now 600 pedigrees covering 5000 albinos. Most people would say that albinism was a mutation, but the difficulty arose, How was it to be classified at all? No simple category of albinotic or non-albinotic would cover it. There was every grade of albinism in both man and animals. When a necropsy was made on a man who had passed all his life as an albino pigment was found in all directions in his body. Was he really an albino or not? The classification of such people into albinotic and non-albinotic could not be carried far. He could give other illustrations of things or conditions which were said to be present or to be absent. The difficulty was to know whether they were really present or absent. There were many grades of albinos which could not be distinguished sufficiently ophthalmoscopically. About 100 specimens of hair albinos had now been examined and there was diffuse pigment in nearly all of them. The same could "specially qualified to practise dentistry," although he avoided the assumption of any specific professional title. The scope of this judgment is far-reaching and its effect may be to check certain flagrant abuses against which the dental profession have long and earnestly protested. The position, often maintained in the Council and elsewhere, that the Dentists Act is more effective than the Medical Acts in the restrictions it imposes on the false assumption of professional status and skill, is vindicated. The efforts of the British Dental Association in this and other cases to elicit by judicial pronouncements the full bearing of the Dentists Act as regards unqualified practice, whether by companies or by individuals, have been unremitting and are amply justified by their success. In its desire for the improvement of professional methods and standards of conduct the Dental Association has addressed to the Council a request that it should forthwith legislate against the practice of advertising by registered dentists. The end in view is good, and merits the Council's serious consideration, but it may be questioned whether the means suggested are within the Council's present powers. Our legal advisers will probably have some counsel to offer on the subject during the session. A small number of penal cases will require your careful attention. They are not without gravity, but none of them are likely to occupy so much of your time as one into which you inquired in May last. The appeal against your decision in that case, of which some mention was made at the time, has not taken place. The duration of the last session, protracted by causes beyond our control, involved a serious strain upon the Council. There is every reason to expect that we may be able in some measure to redress matters by confining the labours of the present session within the limits of this week.

In conclusion, I have pleasure in reporting that the improved system of keeping in the office the documents relating to the registers, which has been in preparation for several years, has now been completed both for the Medical and for the Dentists' Register. For each registered practitioner a separate file is provided, in which every paper referring to his career, with his successive changes of address, &c., is preserved. These files are so arranged that immediate reference can be made to every document relating to his registration, and thus any question respecting him can be rapidly and conveniently answered. Already the system has proved itself to be of great utility as regards the ascertaining and maintaining of the accuracy of the registers. The skill and labour bestowed on this important work by the registrar and his assistants have been great and deserve the grateful acknowledgments of the Council. It is proposed in the beginning of next year to issue a circular of inquiry to every registered practitioner, with a view to eliminate as far as possible all remaining errors from the Register.

The President having been formally thanked for his address, the tables showing the results of the last competitions for medical commissions in the Navy, Army, and Indian Army were received and entered on the minutes. A debate, adjourned from last session, followed on the duties of the assistant examiners at the Apothecaries' Hall, Dublin.

Wednesday, Nov. 25th.

The time of the meeting was occupied by the consideration of one penal case.

Medical News.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—H. R. Coombes (Section II.), Cambridge and Westminster Hospital.

Medicine.—H. R. Coombes (Sections I. and II.), Cambridge and Westminster Hospital; G. F. C. Harvey (Section II.), London Hospital; and F. H. P. Wills (Sections I. and II.), St. Mary's Hospital.

Forensic Medicine.—N. B. Benjafield, University College Hospital; and R. B. Dawson, Guy's Hospital.

Midwifery.—H. R. Ibbotson, Leeds; J. J. S. Rowe, Charing Cross Hospital; and G. F. Wilson, London [illegible]

The diploma of the Society was granted [illegible] entitling them to practise medicine, sur[illegible] Coombes, R. B. Dawson, and G. F. C. Harvey.

Royal College of Surgeons in Ireland: Fellowship Examination.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

R. Bury, J. Craig, P. F. Foran, A. F. Penny, J. Rankin, and P. Sheridan.

The following candidates have passed the primary part of the Fellowship Examination:—

H. A. Driver, J. Gormley, T. M. Thomson, and F. W. Warren

Trinity College, Dublin.—At the Final Medical Examination, Part II., held recently, the following candidates were successful:—

Medicine.—Desmond Drew, Richard J. Attridge, David J. Miller, Henry H. Ormsby, Norman P. Jewell, Wellesley R Allen, Alexander S. M. Winder, James P. S. Dunn, Harold S. Sugars, Frank N. Smartt, Howard S. Millar, Richard FitzGerald, and Joseph B N. Ryan.

Surgery.—Gerald G. Mecredy, Henry R. Kenny, Harold S. Sugars, James F. Clarke, Richard J. Attridge, George Halpin, Norman P Jewell, William A. Nicholson, Gordon A. Jackson, Herbert V Stanley, Alexander S. M. Winder, John C. Baker, Frank N. Smartt, and Thomas Ryan.

Foreign University Intelligence.—*Berlin:* Dr. Felix Hirschfeld, *privat-docent* of Medicine: Dr. Georg Abelsdorff, *privat-docent* of Ophthalmology; and Dr. Alfred Blaschko, the well-known dermatologist, have been granted the title of Professor.—*Berne:* Dr. Emil Bürgi, Extraordinary Professor of Medical Chemistry and Pharmacology, has been promoted to the Ordinary Professorship.—*Cologne (Academy of Practical Medicine):* Dr. Rudolf Graessner, Senior Staff-Surgeon in the Prussian Army, has been granted the title of Professor.—*Ghent and Liége:* A new diploma of *Medecin-hygiéniste* has been instituted by Royal Warrant. Candidates must possess the degree of Doctor of Medicine, Surgery, and Midwifery and must spend a year in special studies. The examination comprises subjects similar to those required for public health diplomas in English universities.—*Harvard:* Dr. A. Christian has been appointed to the chair of Medicine.—*Leyden:* Dr. E. Gorter has been recognised as *privat-docent* of Children's Diseases.—*Nantes:* Dr. Monnier, Professor of Pathology, has been transferred at his own request to the Chair of Clinical Medicine, in succession to the late Dr. Hervouet.—*Philadelphia (Woman's Medical College of Pennsylvania):* Mrs. Harriet L. Hartley, M.D., has been appointed Professor of Surgery.—*Rouen:* Dr. Brunon, Professor of Internal Pathology, has been transferred at his own request to the Chair of Clinical Medicine, in succession to the late Dr. Olivier.—*Wurzburg:* Dr. Ackermann has been recognised as *privat-docent* of Physiology.

The Royal Dental Hospital of London.—The annual dinner of the staff and past and present students of this hospital was held at the Whitehall Rooms. Hôtel Métropole, on Saturday, Nov. 21st, when Mr. W. B. Paterson occupied the chair. He was supported on his right by the President of the Royal College of Physicians of London and on his left by the President of the Royal College of Surgeons of England. After the usual loyal toasts the chairman proposed that of "The Past and Present Students of the Royal Dental Hospital and the Dental School" and in an attractive speech recounted some interesting reminiscences of his student days at the hospital and referred to the happy relationships that existed between the staff and students. Mr. J. S. Amoore and Mr. F. G. H. Armin, the former representing the past and the latter the present students, responded. The dean, Mr. J. F. Colyer, replying for the school, referred to the progressive policy of its staff and mentioned that amongst other things which had proved useful in the equipment of the school was the comparatively recent inauguration of a bacteriological department and an x ray department. He attached considerable educational importance to the hospital *Gazette*, by means of which students who had left the hospital for practice could become acquainted with the advances that dental surgery was making. He preached the cult of the clean mouth and reminded his hearers that those who gave close attention to the subject were after all studying part of the great subject of medicine. The toast of "The Visitors" was proposed by Mr. D. P. Gabell, to which Sir Richard Douglas Powell replied. He said that the physician was in keen sympathy with the work of the dental surgeon, which contributed their offspring was as much as 43·15, but the risk of infection in these cases was doubled. His present opinion until more conclusive evidence was brought forward was that which he arrived at 15 years ago—namely, that susceptibility to suffer from tuberculous infection was a racial characteristic of human beings and that there was not sufficient evidence to prove that any special specific predisposition to that disease was transmitted by heredity by some individuals more than by others.

The debate was adjourned to Nov. 26th.

SANITATION IN INDIA.

The Annual Report of the Sanitary Commissioner with the Government in India for 1906.

THE annual report of the Sanitary Commissioner with the Government in India for the year 1906 was issued a few weeks ago. It would seem that these annual reports which are so full of interesting details concerning the state of the sanitation as exhibited in our great dependency regularly appear some two years after the year with which they deal has passed. *This is probably accounted for by* the large bulk of work that has to be collected from many provinces and embodied in a comprehensive survey. An immense amount of information is contained in these reports, for they deal with the health of both the European and native armies of India, with the jails of India, the vital statistics of the general population, the history of the chief diseases of the population, and with the general history of vaccination, as well as with the sanitary works that have been, or are being, undertaken, and conclude with valuable general remarks on special subjects. In the report under review these last embrace the Red Sea pilgrim traffic, the work of the research laboratories in India, and special inquiries into diseases such as enteric fever, dysentery, malaria, blackwater fever, and kala-azar. Investigations regarding piroplasma, rats, and biting flies are described also. This short summary is sufficient indication of the range of the report; without describing it further we may notice briefly some of the special work which has been performed.

Enteric fever is receiving now very careful attention, and considering the ravages which this disease has caused amongst our troops, we are glad to note that at length some fruitful results seem likely to reward the labours of the medical officers concerned. Notable advances in our knowledge of important problems connected with the disease have been recorded. These advances have resulted in great part from the new impulse which has been given to its investigation by the work of Koch and his followers, and are of so striking a character as to give good reason to hope that before very long most of these vexed problems will be solved finally. The lead given by the Germans has been followed enthusiastically in India and the committee of investigation at the Central Research Institute at Kasauli has obtained results of engrossing interest and far-reaching importance. Captain Greig, I.M.S., the officer who has been temporarily in charge of the bacteriological inquiry, has written a most interesting interim report. Thus the subject of paratyphoid fever has been fully entered into and its special signs portrayed. The importance of the rôle of convalescents and the so-called "bacillus carriers" has claimed attention, and the effect of contaminated drinking water has been found to be the *cause* of infection in a decreased degree. The Government of India has arranged as the result of a representation from the Duars Planters' Association that an inquiry into the prevalance of blackwater fever in these districts should be instituted. A careful preliminary survey of the *conditions existing* in the tea gardens was made by Dr. C. A. Bentley and as a result of his important observations material available for the study of the disease has been gathered sufficient to *render* a successful investigation possible.

An important fact respecting *kala-azar* has been determined by Captain W. S. Patton, I.M.S., at the King Institute at Guindy. He has found that the parasite undergoes development in the body of a species of bed-bug. Much work has also been undertaken in order to determine the correct zoological position of the Leishman-Donovan parasite, which seems to show that it is not a piroplasma.

A comprehensive study of the identification of the rats of India has been begun and an inquiry is being prosecuted respecting the biting flies of India, and one of the most important researches in the department has been to determine whether the tsetse fly occurs in India, in view of the possibility that cases of sleeping sickness may be imported there. No evidence of the presence of this fly has so far been obtained.

A considerable number of admissions for Malta fever are noted, especially in the Punjab, in a full account of the disease by Major C. N. C. Wimberley, I.M.S., who has shown that 100 days or more were a common duration of the fever, relapses being frequent, whilst pain and effusion into joints were present in most cases. The blood agglutinated the micrococcus Melitensis in dilutions as high as 1 in 1280 and in one case as high as 1 in 5120. Such are a few of the facts that have been found out since the last report, which fully bears out our opinion of the large amount of sanitary work that has still to be done in India.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7571 births and 4651 deaths were registered during the week ending Nov. 21st. The annual rate of mortality in these towns, which had been equal to 15·0 and 15·9 per 1000 in the two preceding weeks, declined again to 15·6 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these towns averaged 14·5 per 1000, and in London the mean rate in the same period did not exceed 13·8. The lowest annual death-rates in these towns last week were 6·1 in Handsworth, 7·3 in Hornsey, 8·3 in Reading, and 8·8 in East Ham; the rates in the other towns ranged upwards, however, to 26·0 in Stockport, 26·8 in Wigan, 27·0 in Rotherham, 31·4 in Stockton-on-Tees, and 33·8 in Middlesbrough. In London the death-rate during the week did not exceed 14·8 per 1000. The 4651 deaths from all causes in the 76 towns showed a decline of 113 from the number returned in the previous week, and included 422 which were referred to the principal epidemic diseases, against 567, 470, and 434 in the three preceding weeks; of these 422 deaths, 139 resulted from diarrhœa, 126 from measles, 56 from diphtheria, 40 from "fever" *(principally* enteric), 35 from whooping-cough, and 26 from scarlet fever, but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 1·4 per 1000, corresponding with the rate that prevailed in the previous week; in London the death-rate from these diseases last week did not exceed 1·1 per 1000. No death from any of these epidemic diseases was registered last week in Birkenhead, Leyton, Southampton, Hornsey, York, or in six other smaller towns; the annual death-rate therefrom, however, ranged upwards in the other towns to 3·9 in St. Helens and in Huddersfield, 9·0 in Rotherham, and 9·6 in Middlesbrough. The 139 deaths attributed during the week to diarrhœa in the 76 towns showed a further decline of 13 from the numbers in recent weeks, and were fewer than in any week since the middle of July; the highest annual death-rates from this cause during the week were, 1·6 in Walsall, 1·9 in Blackburn, and 2·9 in Grimsby. The fatal cases of measles, which had steadily increased in the eight preceding weeks from 31 to 104, further rose to 126 during the week under notice; they caused death-rates equal to 3·0 in Leicester, 3·3 in Huddersfield, 5·5 in Middlesbrough, and 7·4 in Rotherham. The 56 deaths from diphtheria showed a further decline of four from the high numbers returned in the two preceding weeks; this disease, however, caused death-rates exceeding 1 per 1000 in Wolverhampton, Middlesbrough, St. Helens, and Devonport. The deaths referred to "fever" during the week were 40, against 41 and 45 in the two preceding weeks; two deaths from "fever" were recorded in St. Helens, equal to an annual rate of 1·1 per 1000. The 35 deaths from whooping-cough showed a further slight increase upon recent weekly numbers, whereas the 26 fatal cases of scarlet fever were fewer by 13 than those returned in the previous week; 13 deaths from scarlet fever were "specially qualified to practise dentistry," although he avoided the assumption of any specific professional title. The scope of this judgment is far-reaching and its effect may be to check certain flagrant abuses against which the dental profession have long and earnestly protested. The position, often maintained in the Council and elsewhere, that the Dentists Act is more effective than the Medical Acts in the restrictions it imposes on the false assumption of professional status and skill, is vindicated. The efforts of the British Dental Association in this and other cases to elicit by judicial pronouncements the full bearing of the Dentists Act as regards unqualified practice, whether by companies or by individuals, have been unremitting and are amply justified by their success. In its desire for the improvement of professional methods and standards of conduct the Dental Association has addressed to the Council a request that it should forthwith legislate against the practice of advertising by registered dentists. The end in view is good, and merits the Council's serious consideration, but it may be questioned whether the means suggested are within the Council's present powers. Our legal advisers will probably have some counsel to offer on the subject during the session. A small number of penal cases will require your careful attention. They are not without gravity, but none of them are likely to occupy so much of your time as one into which you inquired in May last. The appeal against your decision in that case, of which some mention was made at the time, has not taken place. The duration of the last session, protracted by causes beyond our control, involved a serious strain upon the Council. There is every reason to expect that we may be able in some measure to redress matters by confining the labours of the present session within the limits of this week.

In conclusion, I have pleasure in reporting that the improved system of keeping in the office the documents relating to the registers, which has been in preparation for several years, has now been completed both for the Medical and for the Dentists' Register. For each registered practitioner a separate file is provided, in which every paper referring to his career, with his successive changes of address, &c., is preserved. These files are so arranged that immediate reference can be made to every document relating to his registration, and thus any question respecting him can be rapidly and conveniently answered. Already the system has proved itself to be of great utility as regards the ascertaining and maintaining of the accuracy of the registers. The skill and labour bestowed on this important work by the registrar and his assistants have been great and deserve the grateful acknowledgments of the Council. It is proposed in the beginning of next year to issue a circular of inquiry to every registered practitioner, with a view to eliminate as far as possible all remaining errors from the Register.

The President having been formally thanked for his address, the tables showing the results of the last competitions for medical commissions in the Navy, Army, and Indian Army were received and entered on the minutes. A debate, adjourned from last session, followed on the duties of the assistant examiners at the Apothecaries' Hall, Dublin.

* Including membranous croup.

AN ALTERNATIVE CHEST-PIECE FOR SKINNER'S STETHOSCOPE.

Mr. H. J. Phillips, medical superintendent of the London Open-air Sanatorium, has sent us a little accessory for Skinner's stethoscope which he has devised, and which is made by the Holborn Surgical Instrument Company, Limited. It consists of a vulcanite chest-piece of the same circumference as the lower metal end of the stethoscope, which can be used in children and other patients whose costal inter spaces are too narrow for the accurate apposition of the full-sized chest-piece. Mr. Phillips's idea is not new; we remember that a physician to a general hospital employed a similar chest-piece 20 years ago, but we mention it as it may be useful to practitioners who do not care to apply the bare metal of a stethoscope's Y-piece directly to the chest.

OUTSIDE BALCONIES TO HOSPITALS.

THE Secretary of a provincial general hospital of 75 beds finds himself in the fortunate position of having some money to spend. This money has been provided for the construction of outside balconies communicating with certain of the wards. But he and his committee would like to see a few hospitals where these balconies either form part of the original building or have been added in a satisfactory way. Perhaps some of our readers can give the desired information,

◆

Phthisis.—Our correspondent, being a medical man. could probably obtain the information he desires direct from the author. We have no further information than that sent us by our correspondents, and think it quite likely that the paper was not read *in extenso*. We could possibly forward a letter.

Anonymous.—We should like to receive for our own satisfaction a communication from the pharmaceutical chemist who has inclosed to us a communication from Dr. Kilmer and Co., manufacturing chemists.

A. L. F.—In our view the bond is meant to exclude such posts as our correspondent mentions.

J. C.—Will our correspondent kindly repeat his question?

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—J. Gray Duncanson, H. Charles Cameron): at 4.30 P.M.

Papers:

Prof. Ralph Stockman: The Action of Salicylates in Rheumatic Affections.

Dr. David B. Lees: The Effective Treatment of Acute and Subacute Rheumatism.

THURSDAY.

NEUROLOGICAL SECTION (Hon. Secretaries—Leonard G. Guthrie, E. Farquhar Buzzard): at 4.30 P.M.

Clinical Meeting:

Cases will be shown by Dr. Turney, Dr. Batten, Dr, Collier, Dr. Gibb, Dr. Buzzard, and others.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—George C. Cathcart, Atwood Thorne): at 5 P.M.

Cases and Specimens:

Dr. Dundas Grant: (1) Immobility of Left Vocal Cord; (2) Epithelioma of Uvula and Soft Palate.

Mr. T. Jefferson Faulder: (1) Stenosis of Larynx in a Child; (2) Cervical Fistula in a Boy.

Dr. J. W. Bond: (1) Epithelioma of Palate in a Boy aged 16; (2) Fibroma of Naso-pharynx.

Dr. Pegler: Tuberculous Granuloma of Triangular Cartilage of, Septum.

Mr. A. L. Whitehead: Skiagram of Empyema of Frontal Sinus.

Dr. Jobson Horne: Lupus of the Epiglottis.

Dr. Andrew Wylie: Osteo-fibroma of the Maxilla.

Mr. G. Seccombe Hett: Abnormalities of Septum in Animals.

SATURDAY.

OTOLOGICAL SECTION (Hon. Secretaries—W. H. Kelson, Hunter F. Todd): at 10 A.M.

Cases, &c.:

Mr. A. L. Whitehead: A Case of Thrombosis of the Right Lateral Sinus, in which the Clot extended beyond the Torcular Herophili into the Lateral Sinus of the Opposite Side; Operation; Recovery.

Mr. Sydney Scott: A Case of Cerebellar Abscess Secondary to Infective Labyrinthitis associated with Acute Inflammatory Œdema of the Brain; Recovery; Details of Operative Procedures.

Mr. C. E. West and Mr. Sydney Scott: A Case of Infective Meningitis Secondary to Infection of the Labyrinth successfully treated by Trans labyrinthine and Lumbar Drainage.

Mr. C. E. West: A Case of Purulent Encephalitis treated by Drainage and Removal of Infected Brain Tissue.

Mr. MacLeod Yearsley: Microscopic Slide of a Tumour of the Auditory Nerve (shown at the last meeting).

Mr. Urban Pritchard: Syringe for Use after the Radical Post-aural Operation, &c.

Mr. A. Cheatle: Specimens illustrating the Surgical Anatomy of the Temporal Bone.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

CHILD STUDY SOCIETY LONDON, Parkes Museum, Margaret-street, W.

THURSDAY.—8 P.M., Dr. F. H. Hayward: Education and Recent Studies in Heredity.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Proposed Dinner. Clinical Cases.

RÖNTGEN SOCIETY, 20, Hanover-square, W.

THURSDAY.—8.15 P.M., Dr. H. Manders: Phenomena observed in Electrical Currents of Continuous Oscillation.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8.30 P.M., Dr. S. D. Clippingdale: *West London Rivers, Extant and Extinct, and their Influence upon the Fertility and Salubrity of the Districts through which they Pass or Passed.*

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-Fields, W.C.

MONDAY.—12 (noon), Prof. Shattock: *Lipoma.* (Museum Demonstration.)

FRIDAY.—5 P.M., Sir W. Watson Cheyne, Bart.: The Treatment of Wounds. (Bradshaw Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Dr. S. R. Wells: Some Points in the Diagnosis and Treatment of Diseases of the Aortic Valve.

TUESDAY.—4 P.M., Dr. G. A. Sutherland: Clinique (Medical). 5.15 P.M., Dr. H. Campbel' [illegible] Disease.

WEDNESDAY.—4 P.M., Mr. M. [illegible] 5.15 P.M., Lecture:—Dr. C. R. Box: [illegible] Epiphyses in Infants and Young Children.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. Carless: *Some Points in the Surgery of the Biliary Passages.*

FRIDAY.—4 P.M., Mr. W. Dodd: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Mr. Etherington-Smith: Demonstration on Surgical Cases. 12 noon, Dr. Low: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture —Dr. Saunders: Clinical.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Hood: Some Clinical Observations on Heart Disease.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Pritchard: On the Diagnosis and Treatment of Diphtheria.

THURSDAY.—10 A.M., Mr. Etherington Smith: Demonstration on Surgical Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., *Operations.* 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear, 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Ethrington-Smith: Fistula.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Sir Dyce Duckworth: Medicine. 3.15 P.M., Mr. Turner: Surgery. 4 P.M., Mr. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. Carless: Su [illegible] Diseases of the Skin. Out-p [illegible] Surgical and Medical. 12 [illegible] Lecture:—Prof. Hewlett: The [illegible]

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations.—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations —10 A.M., Surgical and Medical. 12 noon, Ear and Throat. Special Lecture:—Dr. Rankin: Aphasia.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations.—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics —10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. Carson); X Rays. 4.30 P.M., Medical In-patient Clinic (Dr. A. J. Whiting).

Battalion, to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). 5th Battalion, The Prince of Wales's Own (West Yorkshire Regiment): The undermentioned officers, from the 1st Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Lieutenant-Colonel Frederick Shann, Surgeon-Major Alexander Reid Stoddart, and Surgeon-Captain Ernest Solly. 5th Battalion, The Prince of Wales's Volunteers (South Lancashire Regiment): Surgeon-Lieutenant Ralph R. Brunskill to be Surgeon-Captain (dated August 19th, 1908). 5th Battalion, The Welsh Regiment: Surgeon-Lieutenant Evan J. T. Jones to be Surgeon-Captain (dated April 1st, 1908). 4th Battalion, The King's Own (Yorkshire Light Infantry): The undermentioned officers, from the 1st Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Lieutenant-Colonel Edwin Lee and Surgeon-Captain George Symers Mill. 5th Battalion, The King's Own (Yorkshire Light Infantry): Surgeon-Captain Vyner Graham, from the 2nd Volunteer Battalion, The York and Lancaster Regiment, to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 4th (Hallamshire) Battalion, The York and Lancaster Regiment: The undermentioned officers, from the 1st Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain Duncan Gray Newton, Surgeon-Captain Sidney Frederick Barber, Surgeon-Captain William Smith Kerr (to be supernumerary), and Surgeon-Lieutenant Christopher Addison (to be supernumerary). 5th Battalion, The York and Lancaster Regiment: The undermentioned officers, from the 2nd Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain Alfred Robinson and Surgeon-Lieutenant Harold Forster Horne.

Royal Army Medical Corps.

Sir John Williams, Bart., K.C.V.O., is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the Welsh Territorial Division (dated Sept. 21st, 1908). John Edwin Eddison is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the West Riding Territorial Division (dated Oct. 1st, 1908).

For attachment to units other than medical units.—John Charles Reynolds Robinson, late Captain 1st Norfolk Royal Garrison Artillery (Volunteers), to be Captain (dated April 1st, 1908). James Malpas (late Captain, 3rd (Duke of Connaught's Own) Volunteer Battalion, The Hampshire Regiment), to be Captain (dated April 1st, 1908). Surgeon-Captain Oliver Eaton, from the 1st Devonshire Royal Garrison Artillery (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Captain John L. London to be Major (dated June 9th, 1908). Captain James A. Wilson to be Major (dated June 19th, 1908). Captain James Cameron to be Major (dated Sept. 1st, 1908). Lieutenant Neish P. Watt to be Captain (dated June 12th, 1908). Andrew Robertson to be Lieutenant (dated June 9th, 1908). David James Graham to be Lieutenant (dated July 3rd, 1908). Captain Alexander E. Watson resigns his commission (dated June 25th, 1908). Lieutenant John L. Rankine resigns his commission (dated August 18th, 1908). Herbert Ernest Corbin to be Lieutenant (dated Sept. 24th, 1908). Robert William Mayston to be Lieutenant (dated Oct. 27th, 1908).

Notts and Derby Mounted Brigade Field Ambulance: Captain Lewis Walter Pockett, from the Royal Army Medical Corps, Territorial Force, to be Lieutenant-Colonel (dated April 1st, 1908). Surgeon-Lieutenant Alexander Robert Tweedie, from the 3rd Kent Royal Garrison Artillery (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). Arthur Briggs Dunne to be Lieutenant (dated August 17th, 1908). Oswald Kentish Wright to be Lieutenant (dated August 17th, 1908). William Henry Rowell to be Lieutenant (dated Oct. 1st, 1908). Walter Harington Fisher, to be Lieutenant (dated Oct. 1st, 1908).

2nd South-Western Mounted Brigade Field Ambulance: Arthur Cary (late Major, 1st Devonshire and Somersetshire Royal Engineers (Volunteers)), to be Major (dated April 1st, 1908).

Yorkshire Mounted Brigade Field Ambulance: Captain George Herbert Leonard Hammerton, from the South Yorkshire Brigade Bearer Company, Royal Army Medical Corps (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

3rd East Lancashire Field Ambulance: Wilson Harold Percy Hey to be Lieutenant (dated August 24th, 1908).

3rd Lowland Field Ambulance: Henry John Dunbar to be Lieutenant (dated Oct. 22nd, 1908).

1st Southern General Hospital: George Jordan Lloyd (*formerly* Surgeon-Lieutenant, 1st Volunteer Battalion, The Royal Warwickshire Regiment), to be Lieutenant-Colonel (dated June 3rd, 1908); James Edward Hill Sawyer to be Major (dated June 3rd, 1908).

4th Southern General Hospital: Charles Edmund Russel Rendle (formerly Captain, 4th Volunteer Battalion, The Devonshire Regiment), to be Lieutenant-Colonel (dated Sept. 30th, 1908). Henry Woolmington Webber (formerly Captain, Devon Bearer Company, Royal Army Medical Corps (Volunteers)), to be Major (dated Sept. 30th, 1908).

Captain Leonard Wood, Royal Army Medical Corps, to be Adjutant of a School of Instruction (dated Oct. 30th, 1908); Captain Francis M. Parry, Royal Army Medical Corps, to be Adjutant of a School of Instruction, vice Captain Langford N. Lloyd, D.S.O., whose *tenure of that appointment* has expired (dated Nov. 1st, 1908); Captain Langford N. Lloyd, D.S.O., Royal Army Medical Corps, to be Adjutant of a School of Instruction, vice Captain Edgar T. Inkson, V.C., whose tenure of that appointment has expired (dated Nov. 1st, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (*Volunteers*): 1st Devonshire: Surgeon-Lieutenant Harold C. Adams resigns his commission (dated April 1st, 1908). 7th Lancashire: Surgeon-Lieutenant (Honorary Captain in the Army) Charles J. J. Harris resigns his commission (dated March 31st, 1908).

THE RESULTS OF SANITATION IN THE EFFICIENCY OF ARMIES IN PEACE AND WAR.

Under this title Surgeon-General Sir Alfred Keogh, K.C.B., Director-General of the Army Medical Service, delivered a lecture at a meeting of the Royal Sanitary Institute held on Nov. 18th under the presidency of Colonel J. Lane Notter, R.A.M.C. The lecturer pointed out that in times of peace measures of sanitation were limited only by their cost. In time of war sanitation must be subordinated to the leading principle of strategy—to get the greatest number of men to the decisive point in the shortest time. As showing what could be done by carefully thought-out sanitary schemes he contrasted the failure of the Ashantee campaign of 1854 with the success of that in 1873. As evidence of what careful sanitation did in the eighteenth century, he described the work of the 7th Dragoon Guards (Black Horse) in the Flanders campaign, when only six men died from illness in five years.

The King has been graciously pleased to accept from Staff-Surgeon Henry Hunt, R.N., a copy of his book, entitled "Naval Sketches."

LITERARY INTELLIGENCE.—Three books connected with the tropics are shortly to be published by Messrs. J. and A. Churchill: "Report on the Prevention of Malaria in Mauritius," by Professor Ronald Ross, C.B., F.R.S. (the book includes many illustrations and charts and is issued by the authority of the Crown Agents for the Colonies); a new volume of studies from the Institute of Medical Research, issued by the authority of the Government of the Federated Malay States; and "Lessons on Elementary Hygiene, for Especial Use in Tropical Climates," by Dr. W. T. Prout, C.M.G.—Simultaneously with the publication of the cheap and revised edition, "Alcohol and the Human Body," by Sir Victor Horsley and Dr. Mary Sturge, the issue of a complete set of slides illustrating the same is announced by the National Temperance League, 34, Paternoster-row, London, E.C., which has obtained the right of reproduction from the original figures, tables, and plates.

Communications, Letters, &c., have been received from—

A.—Monsieur J. Astier, Asnières; Aberdeen City Fever Hospital, Medical Superintendent of; Mr. F. Alcan, Paris; Messrs. E. J. Arnold and Sons, Leeds; Aberdeen Medico-Chirurgical Society, Hon. dealt with Dr. J. S. Wallace's "The Rôle of Modern Dietetics in the Causation of Disease" and from it (p. 458, *D.S.*, June 3rd, 1905) is taken the following passage: "Dr. Wallace has, we must point out, fallen into one error. He seems to think that the value of the use of hard and resistant food and general exercise of the jaw muscles as prophylactics against dental caries is a new discovery. We do not agree with him, and for this reason. '*Coleman's Manual of Dental Surgery and Pathology*,' published as far back as 1881, contains on pp. 103, 104 an exhaustive argument on this very point. It is thereon pointed out what changes, both in character and preparation, the food of man has undergone during the last few centuries. The differences in his bread, meat, cooking, and manner of devouring his food are fully pointed out, special stress being laid upon the fact that since the introduction of the knife and fork the incisors and cuspidati by which in former ages the meat was torn from the bone have had their office converted into almost a sinecure."

In anticipation of your courtesy,

I am, with thanks,

THE EDITOR OF THE "DENTAL SURGEON."

Nov. 23rd, 1903.

THE ELECTROLYTIC ADMINISTRATION OF DRUGS.

To the Editor of THE LANCET.

SIR,—I would like to point out that cataphoric medication is not only not new to medicine but that it has been used also in dental surgery for many years (personally for 21 years). 11 years ago I wrote[1] describing the *modus operandi* for dissipating periodontitis, alveolar abscess, for obtunding *sensitive dentine*, and for bleaching discoloured teeth by cataphoresis. In another journal[2] I described about 30 cases where I had *inter alia* so obtunded the dentine that it could be drilled for the purpose of "filling" without the slightest pain or else anæsthetised the pulp that it could be extracted without the patient suffering any discomfort. I was therefore somewhat amused when the "Diurnal Reflector" heralded forth cataphoresis as another of its great medical discoveries, especially as the process is probably older than most of us living.

I am, Sir, yours faithfully,

H. FIELDEN BRIGGS, M.D. Brux., L.A.H. Dub.,
L.D.S. Glasg., D.D.S. Univ. Mich.

Eastbourne, Nov. 20th, 1903.

EPSOM COLLEGE: LATE ARCHDEACON THORNTON MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—May I be permitted through your columns to thank the very numerous Old Epsomians of the late headmaster's time (1855 to 1870), so large a proportion of whom are in the medical profession; for their generous donations to this fund, and also to inform them that it has been decided to place a very beautiful stained-glass window in the College chapel as the most fitting memorial to so esteemed a man. The window will be unveiled next Founders' Day and all subscribers will in due course receive notice of, and an invitation to, the ceremonial.

I am, Sir, yours faithfully,

PERCIVAL TURNER,
Honorary Secretary.

London, W.C., Nov. 24th, 1903.

UNUSUAL FOREIGN BODY IN THE EAR.

To the Editor of THE LANCET.

SIR,—The following interesting case came to my consulting-room this week. There is nothing particular about it clinically but the circumstances are certainly very unusual. The patient, a prominent volunteer, came to me complaining of deafness. His account of his case was as follows. He had just purchased some artificial ear drums, and on inserting one he became very deaf indeed; on withdrawing the instrument the deafness remained the same. He was the victim of *suppurating* ears and as a consequence somewhat hard of hearing and hence the attempt to use the *artificial drum*. This great increase of deafness after using the artificial drum brought him to me. On examining his ear I found deep in the canal a pultaceous mass of pus and débris and a black-looking body. On removing this with the forceps it proved to be a large earwig. The patient then told me that last August, being at camp, during one night he was awakened by *fearful humming* and buzzing in the ear. Energetically with his little finger he endeavoured to stop it and finally succeeded; he felt sure that the insect had dropped out, and thought no more about it. It seems strange that this large insect could remain in an ear, and that a suppurating one, for three months without causing more disturbance. How long it would have remained without notice had the patient not attempted to use the artificial drum one can only speculate. It is somewhat singular that whilst in the public mind this insect is so closely associated with the ear one should so seldom find any actual cases.

I am, Sir, yours faithfully,

JOHN FOSTER, F.R.C.S. Edin.,
Ophthalmic and Aural Surgeon, Cameron and Hartlepools Hospitals.

West Hartlepool, Nov. 19th, 1903.

PURE SODA-WATER.

To the Editor of THE LANCET.

SIR,—With reference to your extract in THE LANCET of Nov. 14th from the report of Dr. W. Collingridge, medical officer of health of the City of London, concerning impurities *in soda-water*, I should be glad to point out in your columns, with your permission, that the fault is not so much that of the soda-water manufacturers themselves as that of the public who place, or allow to be placed, the empty bottles in any convenient corner, regardless of the fact that these empty bottles will afterwards be collected, sent back to the mineral water manufacturers, and by them refilled, after washing in a manner which is not always effective. The microbes discovered upon analysis by Dr. E. E. Klein, bacteriologist to the City council—viz.: (*a*) "cocci"; (*b*) "sporing bacilli"; and (*c*) "small Gram-positive non-mobile bacilli, which in shape resembled diphtheroid microbes"—prove, although they gave no Neisser staining or caused any change in a guinea-pig's subcutaneous tissue when injected in large doses, that some of the empty bottles collected must have been deposited, somewhere and for some time, amidst garbage such as anyone with the most elementary knowledge of hygienic principles would seriously avoid. I would like to add that personally I prefer to purchase from a chemist liquid carbonic acid gas in small steel bulbs and then to aerate by this means boiled water in a special syphon provided for the purpose which I also obtained from my chemist. As the syphon is my property, remains in my home, and can be cleaned as often as considered necessary, I feel secure from the ravages of diphtheria, at least from this source.

I am, Sir, yours faithfully,

Nov 18th, 1908. CAUTIOUS.

DEATH CERTIFICATION AND MEDICAL SECRECY.

To the Editor of THE LANCET.

SIR,—I understand that the Brussels Medical Practitioners' College having pointed out to the communal council of that city that the form of death certificate supplied for the cause of death to be filled in by the medical attendant having to be handed open to the family of the deceased obliges the medical man to violate his obligation of professional secrecy, a promise has been given by the director of the sanitary service of the city that a new form for a "confidential medical certificate" shall be supplied. This will be handed, sealed, to the family, and after having been utilised for registration and statistical purposes (for which the name of the deceased is not required) it will be burnt. Thus there will be no permanent record of the cause of death. Surely this, though a most desirable change from the open certificate, which is necessarily sometimes so partial a statement of truth that it is practically false, is carrying medical secrecy to a dangerous length. There are many criminal trials where the certificate of the cause of death plays a very important part and it would surely be as easy to devise a system by

measures are applied to them. There is thus good reason to hope that this year's Haj may escape the infection, though for the next few weeks there will still be some anxiety on this score. Last year's pilgrimage was, it will be recalled, a badly infected one, and there is no doubt that it derived its infection from the pilgrims coming from the North and traversing cholera-infected country in European or Asiatic Russia. There are signs that this year's Haj will be a very numerously attended one, so that it is all the more to be hoped that it will escape the disease.

Constantinople, Nov. 7th.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

(From our Special Sanitary Commissioner.)

WORK OF THE SECTIONS.

A Ministry of Public Health.

New York, Nov. 4th.

It would be difficult to enumerate even in mere catalogue form the great number and variety of questions discussed in the seven sections. Without professing to select the most important I can only in concluding these notices of the discussions mention a few of the topics that happened to have come in my way. Of these also I will only select those that are of practical importance. Among the latter and as in a sense embracing all other questions, is the demand for the creation, in all countries, of a Ministry of Hygiene. The American Association for the Advancement of Science elected a committee of 100 persons to attend especially to public health questions. The president of that committee, Professor Irving Fisher, of Yale University, appeared before the Sixth Section of the Washington Congress and made a speech which clearly proved that he had not realised the fact that he was addressing an international congress. But, nevertheless, he gave very good reasons for "the organisation of all existing national public health agencies into a National Bureau of Public Health, with such power over sanitary conditions connected with factories, mines, tenements, child labour, and other such subjects as are properly within the jurisdiction of the Federal Government and *do not interfere* with the power of the States controlling public health agencies." Of course this motion should have ceased at the words "and other such subjects"; the rest is purely American and therefore does not concern an international congress.

Dr. Henry Ward (Nebraska), and Dr. Luther H. Gulick (New York), while speaking of health measures to protect school children, incidentally supported the proposal to create a health government department. But Dr. F. G. Bushnell (England) imparted an international aspect to the discussion by urging that the chief of the health department should be a member of the Government. In other words, that in all countries there should be a Minister of Public Health. Dr. J. G. B. Bulloch, who is a cousin of President Roosevelt, has joined with many others in advocating the creation of a national department of health, and I am not aware that a single word was said against this proposal. It is therefore very unfortunate that a motion to this effect was not submitted to the final meeting of the entire Congress.

Railway Sanitation.

One of the duties of such a Ministry of Public Health would undoubtedly be to see that uniform measures and regulations were applied to all railway carriages and other public conveyances so as to reduce the risk of contagion or infection while travelling. On this subject some energetic words were uttered at Washington. Dr. H. M. Bracken (St. Paul), who is the executive officer of the Minnesota State Board of Health, led the attack. He said that it was difficult to define the status of a thing which did not exist and there was no such thing as railway sanitation in the United States. There were interstate regulations relative to the transit of hogs, cattle, and commercial products, but any proposal dealing with human beings was rejected on the ground that it might interfere with the autonomous government of the different States. Here was a good opportunity of indicating that what applies to the States of America applied to the different nations of Europe, but, as usual, the international aspect of the problem was missed, yet we have had international agreements in Europe regarding railway passengers and international through trains have to submit to the varying laws of the countries through which they travel. What is now wanted are some uniform regulations in regard to cleaning and disinfecting passenger cars. In America this function is often neglected. A representative of the Pullman Car Company replied to these strictures that their cars were fumigated at regular intervals and each time the carriage is known to have carried a sick person. In answer to questions he confessed that they did not employ detectives to ascertain who was sick, but when informed that there was some danger of infection they fumigated the car, and this at their own expense. The discussion showed how much this question of railway sanitation has been neglected and how necessary it is that in future sanitary experts should help to devise methods for the construction of railway carriages and their sleeping compartments.

Tuberculosis and Factory Legislation.

Of course, the question of ventilation in connexion with tuberculosis came to the front in many discussions. It was studied, as just mentioned, in relation to railway carriages and also as a problem more constantly before us in relation to dwelling-houses, factories, and workshops. But here again the Congress was singularly lacking in precision. Everybody agreed as to the absolute necessity of pure air to prevent tuberculosis, but where is the resolution proving equal unanimity of opinion as to any one special law or measure that all nations might adopt and enforce? A practical proposal was needed indicating how to secure pure air, not under all conditions that might be qualified as Utopian, but at least in one or two industries or in some special categories of dwellings. Dr. G. M. Price (New York) certainly made some comprehensive proposals, and, unlike most of the other American speakers, backed them up by showing how some of his suggestions had already been applied in Europe. He demanded that the State should license all trades and industrial establishments; of course, this is done in many countries and occupations are qualified as salubrious and insalubrious. Then he asked for the preliminary physical examination of candidates for employment, which is already done in regard to certain sorts of work, such as railway servants. This should lead to the study of industrial pathology and has done so in Germany under the direction of the medical staff of the German Krankenkassen-verein. Dr. Price likewise quoted the resolutions of the International Congress of Hygiene held at Berlin in 1907, urging improvement in the medical and sanitary inspection of factories. The statistician of the American Prudential Insurance Company, Mr. F. L. Hoffman, spoke so as to explain that tuberculosis was especially frequent in trades which created a quantity of dust. He classified the dust of 30 different occupations and maintained that if proper measures dealing with the dust and securing efficient ventilation in these trades were enforced some 28,000 lives might be saved annually in the United States alone.

Mr. John Martin (New York) pointed out that of the 46 States only 17 provide by law that factories shall be ventilated so as to remove by means of fans and to render harmless all gases, dust, or other impurities. Only six States insist on the periodical lime-washing or painting of walls and ceilings, and not more than eight States demand a minimum air space for each worker. He urged that every State should by a Federal law be forced to apply the laws of the most progressive State. Professor A. Winslow (Massachusetts) and others showed that where an office or a school was well ventilated there was much less sickness and much more work was done. Nothing is more economical in its effects than to spend money on ventilation. Figures in regard to printers were given setting forth the prevalence of chest diseases where the ventilation was bad and Oldendorff's figures with regard to the terrible percentage of cases of tuberculosis among the iron workers and grinders of Germany were quoted. Altogether there was plenty of evidence forthcoming to prove the inefficiency of factory legislation, especially in the United States, and no one disputed the fact that better and far-reaching laws were urgently needed. In these circumstances it is most unfortunate that no comprehensive resolution was presented to the plenary meeting at the close because they indicate that the usual channel for infection of malignant neoplasms is from bacteria which are normal inhabitants of our tissues—that is to say, auto-infection plays a more important part than infection from without.

In furunculosis the staphylococcus pyogenes aureus, as everyone is aware, is the usual infective organism—that is to say, this condition is an example of auto-infection. I have suggested elsewhere that osteomyelitis, an acute disease due in the very large majority of instances to the staphylococcus aureus, is another illustration of auto-infection.

Mr. S. G. Shattock, in a paper with Mr. W. H. Battle on a case of diffuse osteoma of the femur in reference to the excessive formation of callus which may take place in the repair of a fracture in tabetic patients and others, has suggested that "auto-bacterial infection of the injured parts leading to a chronic inflammation must be kept in mind—i.e., an inflammation arising from the action of micro-organisms already in the tissues, the action of which was held in check until the advent of the injury. And, apart from tabes, there is no doubt that a proper inflammatory process must be invoked to explain the exuberant formation of callus in certain cases."[8] This suggestion, coming from an authority of such vast experience as Mr. Shattock, is a further support of the views which are held throughout this lecture—that the presence of organisms in healthy tissues is of supreme importance, especially with regard to the question of auto-infection.

Besides the few illustrations which have been given of the presence of the staphylococci in normal tissues and their power of exciting for unknown reason acute and chronic infections, we also know that tissues, especially scar tissues, due to the action of these organisms, may at any subsequent period become the seat of a transient inflammation or even of suppuration. I have records of two cases of multiple osteomyelitis of long standing. In each instance although the wounds are now healed occasionally inflammatory or suppurative foci occur in the originally infected tissues or in proximity to the orginal wounds. The staphylococcus aureus can be cultivated when suppuration occurs and both cases readily respond to vaccine treatment. In the intervals the patients are in good health. Both cases certainly serve to illustrate the persistence of cocci in the tissues for indefinite periods without giving rise to ill-effects, except during intervals of reactivation.

Andrewes and Horder[9] have recently published interesting investigations concerning the bacteriology of endocarditis and certain other diseases. In their paper on a "Study of the Streptococci Pathogenic for Man" they refer to a streptococcus so characteristic of saliva, though it is also common in the intestine, that the term "streptococcus salivarius" may justly be applied to it. It is closely allied to the commonest of the intestinal forms, to which they have given the name of streptococcus fæcalis. The streptococcus salivarius, according to these investigators, is of considerable importance in human pathology. They have recorded it as pathogenic in 26 cases. They also refer to a much more pathogenic long chain form of the streptococcus salivarius which seems to have a special connexion with inflammation of the fauces and with scarlet fever. As this particular type of streptococcus occurs in sore throats other than scarlet fever and in the normal alimentary canal they have suggested the term of "streptococcus anginosus." Still further, a group of streptococci has been isolated by them from the human intestine and so characteristic of it that they have labelled it as the "streptococcus fæcalis." They investigated 21 cases of undoubted malignant endocarditis due to streptococci, and to these are added 3 cases published by Mervyn Gordon. Of these 24 cases, 11 were due to the group described by them as the streptococcus salivarius, 6 to the streptococcus anginosus, 4 to the streptococcus fæcalis, 1 to the pneumococcus, and 2 only to the streptococcus pyogenes. They refer to the overwhelming preponderance of the salivary and fæcal types in this condition. Many of the forms are absolutely identical in all their reactions with the commonest saprophytic streptococci of the mouth and gut, and the rest are closely related.

Whether it is correct to classify the streptococci in the manner suggested by Andrewes and Horder is very much open to question, but they have clearly shown that the streptococci met with in many of our common diseases may, as regards cultural and certain other properties, be indistinguishable from the streptococci normally present in the human body. Such results are in full accordance with what occurs in many of the acute and chronic infections due to organisms other than the streptococci.

The Pneumococcus.

This organism was first discovered as the result of the examination of the saliva of a normal person. Dr. Eyre[10] states that he has found it in the saliva in 18 per cent. of normal individuals. It is also commonly found in the normal nose and this organism can often be cultivated from the tonsillar crypts. Dr. Eyre states that the pneumococcus isolated from these sources is of low virulence, sometimes avirulent, at other times it shows a high degree of virulence. It would thus appear that in the vast majority of instances this organism enters the tissues of the body through the respiratory tract and that the cells of the upper air passages form the first line of defence, while the pulmonary tissue constitutes the second. Next to the respiratory system he considers that the alimentary tract is probably the most common channel of entrance.

The Gonococcus.

Recent investigations appear to show that this coccus may remain in the tissues for indefinite periods without apparently producing ill-effects. For various reasons its pathogenicity may be re-established. In one instance the passing of a large urethral sound on a man who had no urethral discharge and had not suffered from gonorrhœa for some considerable period gave rise to urethritis due to the gonococcus. Phagocytes in the urethral pus in this case were packed with gonococci.

The Diphtheria Bacillus.

A. *Experiments on the virulence of diphtheria bacilli found in the mouths of healthy "contacts."*—Dr. Graham-Smith,[11] in an extremely interesting article in the standard work on the "Bacteriology of Diphtheria," points out that the majority of observers consider that diphtheria bacilli recently isolated from clinical cases display considerable differences in their virulence towards guinea-pigs. Further, it has been constantly asserted that the diphtheria bacilli which persist in the tissues gradually lose their virulence, and in course of time become completely non-virulent to laboratory animals. He mentions that in the great majority of cases the bacilli found in the throats of persons who have come in contact with diphtheria patients, but show no signs of the disease, are fully virulent, though some are non-virulent. The virulent bacilli of the patients do not, therefore, seem to suffer a diminution in virulence by transference to healthy individuals.

Aaser, quoted by Dr. Graham-Smith, in an outbreak of diphtheria in a cavalry regiment examined 89 healthy persons. In 17 instances diphtheria bacilli were isolated and all were fully virulent. Bolton in 1896 examined 214 persons who had been more or less exposed to diphtheria and found virulent bacilli in the throats in 41·5 per cent. Dr. Graham-Smith, during an outbreak at Cambridge, isolated and tested the diphtheria bacilli found in the throats of 56 healthy persons who had come into more or less close contact with cases of diphtheria. Out of this number 38 had virulent diphtheria bacilli in their throats and 18 bacilli which failed to show any evidence of pathogenicity.

As Dr. Graham-Smith mentions, these records clearly show that in the majority of healthy persons who have diphtheria bacilli in their throats (which have been derived by contact from clinical cases) the organisms are fully virulent, and do not tend to lose their virulence when persisting in the tissues of a healthy individual without giving rise to any pathogenicity.

[11] G. H. F. Nuttall and G. S. Graham-Smith: The Bacteriology of Diphtheria, Cambridge University Press, 1908.

Dr. BUTTLER and other American veterinary surgeons protested that the outdoor treatment was not effective; that, as a matter of fact, cattle were out of doors for nine months in the year and were tuberculous all the same. Then, again, the use of tuberculin helped to spread the disease, for the cattle thus shown to be tuberculous were sold as soon as possible and thus went to other farms where they contaminated other herds.

Dr. MAYER (Louisiana) said that his State was waiting for the section to decide so as to legislate on the matter, but the section did not decide, so the legislature of Louisiana has been left without guidance.

Dr. A. A. WLADIMIROFF, representing the Superior Medical Council of the Russian Empire, urged that it was necessary to have tuberculin as well as hygiene. The former was the only means of diagnosis. Near St. Petersburg there were milk farms; sometimes as many as 60 per cent. of the cows had been found to be tuberculous. Even when all diseased animals had been eliminated it was necessary to test every year. This gave the veterinary surgeon the right of entry and brought about an annual review of all the cattle.

Professor ARLOING (Lyons) thought that milch cows should be tested twice a year and all doubtful milk pasteurised. Veterinary surgeons should control dairies for other reasons besides the prevention of tuberculosis, and he described epidemics of enteric fever which had been traced to dairies.

Dr. MAYER protested that too much reliance was placed on tuberculin. It was wrong to lose sight of clinical diagnosis and he did not believe that a syringe would prove a full substitute for this hardly acquired knowledge. A clinical report might justify the seizure of cattle but not a tuberculin test.

In replying to the very long discussion that had been held Dr. RUTHERFORD explained that meat inspection in Canada was only a year old. Deaths had been traced to unwholesome food and insanitary dairies. What, however, was the use of tracing tuberculosis to a farm if there was no legal means of action?

Altogether, it will be seen that the whole question is still in need of crystallisation. Some more clearly defined proposals likely to be supported by a majority of experts have yet to be brought forward. Nevertheless, much work has been done.

Dr. A. D. MELVIN, chief of the United States Bureau of Animal Industry, was able to report that in 15 years, 1893 to 1908, Federal and State officials had had tested with tuberculin 400,000 cattle, mostly dairy cattle, and 37,000 reactions had been obtained. This meant 9·25 per cent. They found that on an average 10 per cent. of the milch cows, only 1 per cent. of other cattle, and 2 per cent. of the hogs were infected with tuberculosis. This was equal to 3·5 of all cattle. Of 23,860 reacting cattle that were slaughtered, lesions of tuberculosis were found in 23,585, a percentage of 98·81, showing the very great accuracy of the tuberculin test.

Dr. JOHN R. MOHLER, chief of the Pathological Division at Washington, pointed out that much valuable information was gained by tracing tuberculous animals at the abattoirs back to the farms whence they came.

This is a good idea and might be adopted in England; thus whenever an animal at a slaughter-house is found to be tuberculous the medical officer of health of the district whence the animal came should be informed so that he might institute an inquiry at the farm in question. It is obvious that all these very practical and urgent questions should be more fully discussed and the chief result of the meeting at Washington is to show the necessity of further and closer investigation.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Health Visitors in the Rhondda Valleys.

THE members of the Rhondda urban district council are to be commended for their action in carrying out the advice of their medical officer of health (Dr. J. D. Jenkins) with regard to the appointment of lady health visitors. Two of these officials are to be appointed forthwith at a commencing salary in each case of £80 per annum, rising to £120. The inspecting staff in the Rhondda has long been undermanned. When there was a population of 80,000 persons there were five inspectors and now that the population has increased to over 120,000 there are only six, so that there is quite room for the services of the two health visitors whom it is proposed to appoint. The salaries to be offered are those which are paid to the sanitary officers.

Improvement of Milk-supplies.

At a meeting of the West of England and South Wales Branch of the Society of Medical Officers of Health held at Bristol on Nov. 19th it was decided to arrange a conference with those interested in the production of milk, in order to discuss the best means to be adopted for the improvement of milk-supplies, more especially with respect to improvements at the sources of supply. Mr. L. M. Bowen-Jones, the President of the branch, urged that although dirt in milk was responsible for much infantile mortality, it was probable that even more children died from the want of milk, so that the milk trade was one which it was in the public interest to foster and to protect. He proposed that local associations of dairy farmers should be asked to formulate suggestions and advice to the trade as to the best available means of improving existing conditions at many dairy farms. It would thus be demonstrated to hostile critics that the farmers themselves realised their responsibilities, while those whose business it is to administer existing laws would be assisted very considerably in their work. He further urged that the dairymen should be made to realise that the trade in which they were engaged was unique, for it dealt with a necessary article of food which formed the almost exclusive diet of a large proportion of the most susceptible units of the population—infants and invalids—and that milk was unique among articles of food in its powers of collecting and fostering micro-organisms which were injurious to health and which might even be fatal to the infant consumer. He expressed the opinion that it was most discreditable to our sanitary administration that the legal powers which it was competent for rural sanitary authorities to exercise had either been entirely ignored or so badly administered that in many rural districts there existed practically no supervision of dairy farms at all.

The Provision of Nurses in Monmouthshire.

An association was recently formed in Monmouthshire for the purpose of training or otherwise providing suitable nurses throughout the county. It is proposed to encourage two grades of nurses—one to include highly-trained fully-certificated district nurses in towns with a population of 5000 persons or more, and another to include midwives fully trained and certificated in accordance with the requirements of the Central Midwives Board. The new association as well as coöperating with existing nursing organisations will itself train suitable women as nurses and midwives. It is proposed to establish a training home at Pontypool for the eastern valleys and another for the western valleys at Tredegar. These are to be utilised as homes of rest for occasional nurses and as residences for emergency nurses. There can be no doubt as to the need for such an association among the industrial sections of the population and if the details of the organisation are properly safeguarded against abuse it will render valuable service.

A County Medical Officer of Health for Pembrokeshire.

The Pembrokeshire county council has referred to the sanitary committee the question of appointing a county medical officer of health. The medical inspection of the school children in the county is at present being carried out by local practitioners, but there has not been appointed any official to direct these inspections or to report upon the results. When the question was under discussion at a recent meeting of the county council more than one member expressed the opinion that it was impossible to carry out the detailed examination of the children which was required by the Board of Education in three or four minutes, and that a fee of 1*s.* or 1*s.* 6*d.* was far too little to pay for a thorough examination.

Cardiff Mental Hospital.

There is accommodation in the new Mental Hospital at Cardiff for 750 patients, including 336 men and 414 women, and in the middle of October there were occupying the wards 351 men and 329 women. The weekly cost per patient is 13*s.* 5*d.* At the last visit of the Commissioners in Lunacy they expressed their regret at the decision of the visiting committee to postpone the erection of an isolation hospital. It species of bacteria, any one of which is capable of originating typhoidal disease—that, in fact, the etiology of this condition is as complex as its symptomatology." "Further, we now also know that this group of bacteria, while at one time originating a disease with all the clinical symptoms of typhoid fever, may at another cause pathological conditions utterly unlike it. Typhoid is, in fact, a group disease produced by a group of organisms." Major Statham refers to a table at the end of his paper, giving a list of five sub-groups of bacteria capable of originating disease in man indistinguishable from typhoid fever. First group, bacillus fæcalis alcaligenes; second group, bacillus typhosus; third group, bacillus paratyphosus A; fourth group, bacillus paratyphosus B; and fifth group, bacillus coli.

It is necessary to refer somewhat fully to these data which have been specially emphasised by Major Statham before speaking of the persistence of these various organisms in the tissues in man, the direct infection they may produce in their host, and the way in which they may set up endemic or epidemic areas of infection. Considerable interest has been given to the question of the so-called "typhoid carriers." I shall not limit in this communication the term "typhoid carrier" to the carrier of the typhoid bacillus, but to the group of organisms already referred to by Major Statham. The entire subject of typhoid infection is outside the scope of the present work, but infection due to the persistence of these organisms in the tissues of man for more or less lengthy periods is probably of greater importance than a similar condition occurring with other bacteria. We now know that the fæces of patients who have recovered from typhoid fever may be infective for months or even years, and it is usually regarded that this is due to infection of the gall-bladder.

While referring to the subject of cholelithiasis and its relation to typhoid bacilli, reference may be made to a paper published by Hartmann, quoted by Moynihan,[14] he examined the bile in 46 cases of cholelithiasis treated by operation. In 36 instances bacilli were present, of which by far the most common was the bacillus coli, but in no instance was the typhoid bacillus cultivated from the bile. Petersen, quoted in the same paper, gives the records of 50 operations for gall-stones. Bacteria were cultivated from the bile in 44 instances, but the typhoid bacillus was never found to be present. The bacillus coli was isolated on every occasion. I have examined the bile at the time of operation for cholelithiasis in some 20 instances, but the bacillus typhosus has only been obtained on one occasion, and the bacillus paratyphosus B once.

It has been estimated that typhoid bacilli may be isolated from the fæces of patients suffering from typhoid fever in from 25 to 30 per cent. of the cases in the first three weeks, from 10 to 15 per cent. in the next two months, 4 per cent. or 5 per cent. for the third month, and finally, according to the investigations of Kayser and Brion and others, that some 1·5 per cent. of the cases become regular typhoid carriers, while Lentz obtained such a high percentage as 4. Kayser collected a large number of individuals who had been two years convalescent from an attack of typhoid fever. Out of 101 cases three still showed the presence of the bacillus and were therefore chronic carriers. In fact, it appears justifiable to assert that about from 3 to 4 per cent. of typhoid convalescents become chronic carriers and of those who have been associated with typhoid cases a small proportion may excrete the bacillus temporarily. Still further it has been shown that those who never had any illness which has been regarded as typhoid fever may have bacilli of the typhoid-paratyphoid group in their fæces. Dr. J. C. G. Ledingham[15] in a most valuable paper read at the British Medical Association at Sheffield this year refers to some investigations which have been made by the Strassburg School on healthy persons living in the vicinity of, or in close contact with, typhoid cases. It has been shown that there are a certain number of temporary or acute carriers who excrete the typhoid bacillus in small numbers for a short time only. These temporary carriers do not appear to be really instances of chronic carriers who intermittently discharge the bacilli, nor do they appear to be cases of ambulatory typhoid, because experience seems somewhat opposed to either view. Scheller refers to a case of a female engaged in the milk trade who was excreting typhoid bacilli and appeared to constitute a focus of infection in the epidemic about to be referred to. All persons in any way associated with this milk trade were examined with the result that 17 other carriers were revealed. Some of these were passing the bacilli in the fæces only, others in the urine only, while in a certain proportion both the fæces and the urine were infected. The female originally discovered was removed from her work in the dairy. Instructions were given to the milkers to wash their hands in lysol, and those who were excreting the bacilli in the urine were treated with urotropin. One month from the time these methods were adopted all the carriers were re-examined bacteriologically with negative results, except in the case of the original female who still continued to pass the bacilli in large numbers. It has been stated that typhoid bacilli are present in the urine in some 30 to 40 per cent. of severe cases and in about 15 per cent. of all cases diagnosed as typhoid fever, and it has been shown that the bacilluria may last for some considerable period and be a serious source of infection.

One of the most interesting cases of a typhoid carrier has been recently recorded by Dr. G. Dean,[16] professor of pathology at Aberdeen. It occurred in the case of a medical man who 29 years before he was seen by Dr. Dean had had a severe attack of typhoid fever. This patient had had attacks of biliary colic for some considerable period sometimes associated with jaundice. The fæces were subjected to a bacteriological examination by Dr. Dean who investigated three samples, and in all of them the typhoid bacillus was demonstrated. The patient's serum gave an agglutination reaction in a concentration of 1:25 on a stock laboratory culture of the bacillus typhosus but would not react with greater dilutions. The patient's own bacillus, however, did not react with his serum, although it was agglutinated by immune horse serum. It may be mentioned that as far as it is known there was no case of infection originating from the patient whose case has just been referred to. The chief interest concerns the persistence of the typhoid bacillus in the tissues for so long a period—assuming that this bacillus entered at the time of the original infection—and did not produce any serious effect on the patient's health nor, as far as is known, cause dissemination of the disease. Attention, however, must be directed to an important observation on typhoid immunity recently made by Dr. Ledingham.[17] He has found that the serum of typhoid carriers shows a high opsonic content for the homologous strains of the bacillus typhosus.

Dr. Alexander Ledingham and Dr. J. C. G. Ledingham[18] have also referred to some interesting cases which occurred in a lunatic asylum in Scotland. The fæces of these patients were subjected to a bacteriological examination in 1907. From the main asylum the fæces of 57 female patients were examined. One of these patients was found to be passing typhoid bacilli in enormous numbers in the fæces. This patient had been in the asylum for 12 years and there was no record of her ever having had typhoid fever. Her serum agglutinated the typhoid bacilli up to a dilution of 1:200. As a case of typhoid fever had occurred in the small asylum the fæces of all the female patients, 34 in number, were systematically examined, and as a result a patient of 60 years of age was found to have typhoid bacilli in the fæces in considerable numbers. This patient had had an attack of typhoid fever in 1895. A third case was also discovered in a patient who had had typhoid fever in 1904. In this communication three patients are mentioned who were passing typhoid bacilli in their fæces, two of whom had had typhoid fever some years previously and one without ever having had any clinical evidence of this disease. These observers also draw attention to a point to which most writers on the subject have referred—namely, the much greater frequency of typhoid carriers among women and also that in women biliary calculi are of such common occurrence.

Levy and Kayser[19] have published a case of a typhoid carrier who had been isolated on Oct. 17th, 1905, and who died on Oct. 18th, 1906, after a short febrile attack. At the post-mortem examination the spleen was slightly enlarged with its results, the teachers imported by Alfred the Great to educate his kingdom, and by Charlemagne to re-civilise and re-Christianise the chaotic débris of the Western Empire were all mentioned, necessarily in very few words. The hereditary physician of the Middle Ages as well as the hereditary harper received a passing word of recognition; the cleavage of the *ars medendi* into two sections which necessarily followed the forbidding of the shedding of blood by members of the clerical orders (by the Council of Tours) was duly referred to—with the engrossment of the practice of surgery by "the barbers and periwig makers," and the establishing of the barbers of Dublin as a guild in 1446, the oldest of the medical guilds of the British Islands, and the original precursor of our Royal College of Surgeons. The work of the latter was appreciatively referred to and the premier position of the Dublin School of Medicine in the past century was indicated. If there was anything in Dr. Moorhead's interesting summary which required some verbal revision I would suggest that it was the apologetic tone in which he referred to the fact that the Irish school had not been distinguished by great *original* contributions to medical knowledge. As a mere matter of fact, Ireland has always furnished the germs of ideas which supplied *originality* and fame to others. Sir Astley Cooper, the "greatest of England's surgeons," owed his cosmopolitan reputation in his specialties to dissections made for him by our own Abraham Collis in the days of his junior professional *wanderjahre!* And this case is but one of 2000.

Royal Hospital for Incurables, Dublin.

The annual sale of work produced by patients in this hospital was formally opened on Nov. 19th by Lady Aberdeen. The exhibition consisted of over 1000 articles, chiefly of clothing and varieties of fancy work. The hospital funds derive nothing from the sale, as the entire proceeds are distributed among the patients in the institution without any discount whatever. The sale has always been a popular one, as the institution stands high in the public estimation. Patients are admitted (on election) from all parts of Ireland, without distinction of creed or politics, the only essential qualifications being poverty and incurable disease.

Richmond Lunatic Asylum: Electricity v. Gas.

The monthly meeting of the Richmond Asylum joint committee, which was held on Nov. 19th, was largely occupied with a discussion of the relative merits and demerits of gas and electricity as illuminating agents from the general view-point of the physicist and engineer and the particular one of the financial and medical representatives and officials of their own institution. After the original suggestions of the desirability of lighting the asylum buildings with electricity the lighting committee of the corporation had approached the joint committee (and also the North Dublin union guardians) on this subject. A subcommittee was appointed by each board. These bodies met and discussed the bearings of the subject very thoroughly. One of the special results of this movement was an offer from the gas company to light both institutions on a revised scale. They practically offered, indeed, to reduce the total amount of their bill by (approximately) 45 per cent., to assume the responsibility of the upkeep of the installation, and to relieve the institution of responsibility in connexion with variations of price. The chairman of the joint committee meeting, however, expressed the opinion that electricity should be adopted. Large extensions of their buildings were about to be made. Electricity was, he considered, cheaper than gas and in course of time it would become cheaper still. It was decided to send the report back to the subcommittee with the view of obtaining further explanation on certain points.

The University of Belfast.

The first meeting of the Belfast Commissioners took place on Nov. 18th at Queen's College, Belfast, Judge Shaw, K.C., being in the chair. The Commissioners appointed Mr. A. Jaffé, M.A. Camb., to be their secretary. They framed a number of questions, in answer to which they invite reports from the corporate body of Queen's College, Belfast. They will meet again on Dec. 29th. The new University is to be called the Queen's University of Belfast.

Compliment to Alderman Dr. J. King Kerr, J.P.

On Nov. 18th Alderman Dr. J. King Kerr, chairman of the public health committee, was, at a public meeting in the City Hall, Belfast, presented with an address and with his portrait by his colleagues in the corporation and a number of friends. His portrait is to be hung in the City Hall. His wife was also presented with a replica and with two silver candelabra. The Lord Mayor presided, the ex-Lord Mayor (Lord Shaftesbury) made the presentation, and speeches were also delivered by Dr. King Kerr, the High Sheriff (Councillor McCaughey), Sir Otto Jaffé, and Dr. Peter O'Connell, a former member of the public health committee, now no longer in the city corporation.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Education Grants.

AMONG the numerous clauses of the budget of public education, which was discussed by the Chamber on Oct. 30th, was one asking for the reinsertion of the clause recommending a grant of 15,000 francs. This clause had been inserted by the Government but was refused by the Financial Committee. The object of the grant was the creation of a chair of special and general hygiene at the Collège de France. The President of the League of Education, M. Dessoye, argued in favour of the grant. The chairman of the Financial Committee, however, said that for a certain number of years past a large number of new chairs had been created at the College of France perhaps not always on entirely scientific considerations. Without asking the Minister of Public Instruction to abandon the right of creating chairs at the College of France the chairman went on to say that he proposed, in all cases except those in which a man of exceptional scientific attainments cannot be overlooked, that the Minister should take the opinion of men competent to pronounce upon the proper sequence of the creation of chairs. He demanded, further, that the chairs at the College of France should be reserved for eminent men who, in addition to the possession of all the necessary diplomas, have a paramount claim by reason of their scientific attainments and by having carried out original research. M. Dessoye stuck to his guns and deplored the fact that France did not possess institutes of hygiene similar to those which exist in Germany and the United States, which should formulate the laws of hygiene after experience founded upon experimental research. The proposal was once more vetoed by 401 votes to 116.

Troubles at the Faculty of Medicine.

The disturbances at the Faculty of Medicine of which I spoke in my letter published in THE LANCET of Nov. 21st, p. 1565, continued. At last on Nov. 16th it became known that on Nov. 14th M. Landouzy, the dean of the Faculty, received a delegation of the students who handed in a series of demands in writing. These were: (1) that only five students should dissect on one body; (2) that the school at Clamart should be re-opened; (3) that first and second year men should not be combined in class; and (4) that the arrangements for the teaching of osteology should be restored as they were, with an examination at the end of the course. The committee of the Faculty whose duty it is to look after the teaching of practical anatomy and whose members are M. Nicolas, professor of anatomy, M. Quénu, professor of operative surgery, M. Marie, professor of pathological anatomy, and the Dean as chairman, are of opinion that a certain number of students should be told off to dissect at Clamart, which course would set free a certain number of tables at the École Pratique. The remaining demands should be referred to the professor of anatomy.

On Ionisation.

At a meeting of the Society of Surgery, held on Nov. 11th, M. Tuffier related some researches which he had recently made into the penetration of the body by drugs under the influence of an electric current. His paper mainly dealt with the use of nitrate of silver in ophthalmia. As for salts which had an affinity for the skin (*en rapport avec la peau*), M. Tuffier considers that they penetrate the skin but do not pass very deeply into the tissues. Also he considers that although the use of sodium salicylates by cataphoresis in painful arthritis is accompanied by relief of the pain, this result is due not to the action of the drug but to the action of the electric current.

The Academy of Medicine.

At the meeting of Nov. 17th M. Quénu was elected a by the presence of the bacillus coli; the patients were suffering from bacilluria and pyuria. They had all suffered from so-called "influenza," one two months previously, another one year, and the third case a few years previously, but in no instance were they known to have contracted typhoid fever. In two of the cases definite urinary symptoms had occurred soon after the attack of "influenza," which in each instance had been severe. No precaution had been taken previously to the isolation of the bacilli, and no case of infection had occurred as far as is known. In two instances the patients were treated with a vaccine prepared from their own organisms, with the result that the paratyphoid bacilli soon disappeared from the urine, although the colon bacilli persisted. In the third example the urine, which only gave a growth of the *bacillus paratyphosus A.*, cleared up under the influence of urotropin and other urinary antiseptics. Although there was no absolute proof, it seems to me very probable that the disease which had been diagnosed as "influenza" was due to infection with the paratyphoid bacilli. The fact that urinary symptoms did not immediately follow the acute illness may be disregarded, because, as previously stated in the case of bacillus coli infections of the urinary tract, it is a matter of common knowledge that urinary infection is often present without the patient being aware of it.

The latent persistence of the typhoid-paratyphoid group of organisms in the tissues is of considerable importance from whatever aspect this subject is considered. That organisms which are known to be capable of giving rise to serious epidemics may practically live as saprophytes in our tissues, with or without occasional periods of activity, or be discharged from our bodies and thus be the source of acute infection in a fresh host, must be regarded as a reason for reconsidering our views concerning these infections, and the credit of this is greatly due to the School of Hygiene at Strassburg.

In conclusion, I must apologise for the numerous omissions in this account of the life of certain bacteria in our tissues. The whole subject is surrounded by difficulties which concern almost every detail in pathology and bacteriology. I have endeavoured to point out certain facts relating to bacteria living and multiplying in our tissues in contradistinction to the growth of these organisms outside the body.

FURTHER NOTES ON THE TREATMENT OF SYPHILIS BY ARYLARSONATES.

BY F. J. LAMBKIN, L.R.C.P. & S. IREL.,

COLONEL, R.A.M.C.

IN a paper which I read at the annual meeting of the British Medical Association at Sheffield in August last I recorded 74 cases of syphilis treated by arylarsonates at the Military Hospital, Rochester Row, between August, 1907, and July 1st, 1908, and I have now to chronicle a series of 34 further cases dealt with in a similar manner between July 1st and Oct. 1st, 1908, of which the following are the notes of some of the most interesting.

CASE 1.—Private ——, Irish Guards, was admitted on July 7th with an indurated phagedænic sore on the glans penis, profuse macular eruption on the body, inguinal and cervical glandular enlargements, nocturnal headaches, and anæmia with loss of body weight. Treatment consisted of 10 grains of soamin given intramuscularly on alternate days until he had received a total of 100 grains. He was discharged to duty on the 26th, all active signs of the disease having cleared up and the general health much improved; he had gained 6 pounds in weight whilst in hospital.

CASE 2.—Private ——, Coldstream Guards, was discharged from the Royal Herbert Hospital, Woolwich, on June 1st; he had been then under treatment for a "hard chancre," receiving 36 inunctions of mercury. He was admitted to Rochester Row on July 8th with an indurated sore on the penis, inguinal, cervical, and mastoid deep glandular enlargements, mucous patches on the tongue and mouth, and a roseolar rash on the body. His weight was He had the usual soamin course, grains by intramuscular injection. All active symptoms disappeared by the 28th when he was discharged from hospital. His weight on discharge was 11 stones 1 pound.

CASE 3.—Sergeant ——, R.A.M.C. This was an old case of some months' standing. He had had only an irregular course of treatment, owing to having concealed his disease. He was admitted to Rochester Row on July 8th with severe ulceration of the inside of the cheeks, tongue, and throat, also orchitis of the left testicle. He was put on soamin at once and completed the usual course of 100 grains, at the end of which all ulceration had healed, the size of the testicle was decidedly smaller, and his general health had markedly improved. He had gained 5 pounds in weight whilst in hospital, from which he was discharged on the 25th. This case was remarkable from the fact that although no local applications were made to the ulcerations in the mouth and throat, they healed in a most remarkable manner under the soamin alone.

CASE 4.—Private ——, Scots Guards, was discharged from the Royal Herbert Hospital, Woolwich, on May 21st; he had been there under treatment 52 days for "soft chancre." No mercury was given. He was admitted to Rochester Row on July 7th with an indurated scar on the penis, the deep glands in the groins, back of the neck, and mastoid shotted; and a maculo-papular eruption scattered over the body and extremities; he suffered from nocturnal headaches, anæmia, and debility, and was much run down. He had albuminuria. He went through the usual course of soamin, under which all symptoms cleared up, the albumin disappeared, and his general health improved in a remarkable way. He was discharged to duty on July 29th. The albumin in this case, as was thought, was due to syphilis which was proved to be correct by the way it cleared up under treatment.

CASE 5.—Private ——, Coldstream Guards, was admitted on July 4th with a well-marked "Hunterian chancre on glans penis"; the deep glands in the groin and neck were enlarged. He had the full course of soamin. The induration disappeared and he was discharged on July 25th, and up to date has had no further development of the disease.

CASE 6.—Driver ——, A.S.C., was admitted on July 7th with a typical hard chancre at the root of the penis. There were no glandular swellings. He went through the full course of soamin. The induration disappeared and he was discharged to duty on the 23rd. Up to date he is quite free from any further developments.

CASE 7.—Private ——, 2nd Grenadier Guards, was admitted on July 30th with a hard phagedænic-looking chancre on the corona glans, enlarged and shotty deep inguinal and cervical glands, a roseolar rash on the body, nocturnal headaches, anæmia, and general debility. He had the full course of soamin, under which all active signs of the disease gave way, and he was discharged to duty on Sept. 3rd, having much improved in general health. He had gained 7 pounds whilst under treatment.

CASE 8.—Sergeant ——, South Lancashire Regiment, was transferred to Rochester Row from another hospital where he had been under treatment for "lupus." The trouble first showed itself in India in 1905, and consisted of at first a more or less superficial ulceration on, and in the vicinity of, the nose. In hospital this was diagnosed as "lupus," and it appears at first to have healed up under local treatment; however, he had many recurrences of the ulceration which eventually necessitated his being invalided home. In England the same state of affairs went on and he spent most of his time in hospital. He had no specific history and had had no specific treatment; the latter consisted of arsenic internally, local applications, scraping, and x ray exposures. At two different hospitals the tubercle bacillus was detected in smears from the nasal ulceration. On admission at Rochester Row on August 5th he was much run down in general condition, cachectic, and anæmic. The alæ of the nose had been destroyed by ulceration which was still proceeding and spreading to the upper lip. There was a deep serpiginous-looking ulcer at the top of the pharynx, and the soft palate had been almost entirely destroyed by previous ulceration. Smears from the ulceration were negative. The case looked decidedly suspicious of syphilis and it was decided to deal with it as such. Accordingly the patient was put on soamin injections, and on August 12th the following note was entered: "Has had four injections of soamin (40 grs.) and the ulceration both of the throat and nose has practically healed." This patient was discharged to his duty on August 30th, having had the usual full course of soamin, 30 years ago, on the occasion of the meeting of the Sacred College to appoint a successor to Pius IX. In the February of 1878 some 60 and more cardinals proceeded to the Vatican, each bound for his special "cella" (room), to take part in the election of a new pontiff. The business involved in the election often extends over days, nay weeks or even months, before the required majority can be got to agree upon the cardinal to be appointed, and so each member of the Sacred College has to take with him the furniture necessary for such a prolonged seclusion from the outer world. Mr. Shakspere Wood, the correspondent above referred to, made it his business to watch each cardinal as he filed into the Vatican with the special appurtenances of his toilet, and, by no means to his surprise, he found that out of the 60 cardinals (or more) on whom he saw the Vatican gates close for an indefinite period there were only two whose personal equipment included a bath, and these were the two English Cardinals—Cardinal Manning and Cardinal Howard. If the princes of the Church, in such overwhelming majority, could dispense with what their British brethren deem so necessary, is it wonderful if their humbler compatriots should be equally resigned to a similar "self-denying ordinance"? The Roman population looks back with pride on its progenitors whose virtues it would fain congratulate itself on inheriting. But one of these was the use of the bath, which the humblest citizen could enjoy in such magnificent establishments as those of Titus, of Caracalla, and of Diocletian, whose very ruins are still among the "Mirabilia" of the Eternal City. It would do well to resuscitate the practice, if only for personal comfort and individual health, to say nothing of the gain to the public in the matter of hygiene, especially on occasions of the *feste* which attract to its basilicas promiscuous crowds of the faithful from all parts of Christendom.

Nov. 21st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Weather and the Water-supply.

A QUITE unexpected calamity has befallen this city in consequence of the protracted absence of rain and of the frost. Although Vienna has boasted of an excellent supply of pure water since the completion of the famous "Hoch-quell Wasserleitung" some 35 years ago, it has happened now that not only has the reservoir nearly run dry but there is a shortage in the daily influx. Vienna requires a daily supply of 1,000,000 hectolitres (one hectolitre is equal to 22 gallons). In normal times this quantity is easily obtained from the mountain springs whence the water is carried in the aqueducts to Vienna over some 70 or 75 miles. But since Sept. 10th there have only been three rainy days and the total rainfall has been estimated at less than three inches. A snowfall some time ago was also of little assistance and the frosts which have continued since then have made matters still worse. It has therefore been decided to cut off a large number of the water pipes in the houses and to diminish the habitual waste of water in baths, hotels, coffee-houses, and many private buildings. The population suffer under these measures but as long as the abnormal conditions prevail the utmost care is necessary to prevent a veritable "water famine."

Abnormal Development of Teeth in a Baby.

A very rare instance of premature development was demonstrated at the last meeting of the Medical Society, when a baby, aged four weeks, was shown with all 20 teeth in his mouth. The child was born at the normal term and is normal in all respects save that the gums are perforated by 20 small, otherwise apparently quite normal, milk teeth in the proper position. The ossification of the bones, the development of hair, and the state of nutrition are in accordance with the age of the baby, a healthy boy. Such occurrences are not frequent, although several instances have been reported within the last few years. The parents are not near relatives to each other and no etiological factor can be suggested to account for the abnormality.

The Proposed New "Infectious Diseases Act."

The Government has just laid before the House of Parliament the outlines for a new "Infectious Diseases Act," to become law within three months. As there are no general rules adopted uniformly in the different countries which constitute the Empire of Austria, and as science has made enormous progress since the last codification of the public health laws, the new regulations take into consideration all these points of view. The following diseases must be notified, without payment, to the public health officer: bubonic plague, cholera, small-pox, abdominal typhus (enteric fever), dysentery, recurrent fever, blackwater fever, leprosy, anthrax, yellow fever, scarlet fever, diphtheria, epidemic cerebro-spinal meningitis, malleus and rabies, glanders, and all suspicious injuries sustained from animals or through animal tissues. In case any other disease should become epidemic or extremely dangerous to the public, the executive is entitled to deal with it as if it were contained in the above-mentioned list. The notification must be made by the medical man, nurse in charge of the case, or by inn- and hotel-keepers, teachers, and coroners. Persons attacked by any one of these infectious diseases must be isolated if necessary. The lodgings and belonging of the patient and his family must be disinfected, and articles which cannot be dealt with in a satisfactory manner must be destroyed. Compensation must be given, however, in every instance of compulsory destruction. Any place or inhabited house may be put in quarantine. Special physicians may be appointed in times of epidemics to give gratuitous medical assistance, and pensions are to be awarded to them should they be incapacitated in the discharge of their duties, the pension to be paid to the family of any such physician who dies. The expenses of sanitary precautions in times of epidemics are to be borne by the State. The Bill contains no clause dealing with vaccination. It is intended in the future to make vaccination compulsory, but it is deemed advisable to postpone the matter until all negotiations with the local boards have been completed. As violent opposition is expected in this respect the Government wants to make its position quite good before embarking on legislation.

The Prevention of Arterio-sclerosis following the Use of Adrenalin.

In a communication to the Gesellschaft der Aerzte, Dr. Mansfeld explained the details of his experiments to prevent arterio-sclerosis by the use of adrenalin. A series of experiments has brought to light the fact that the injection of adrenalin and oily substances was not detrimental to the intima of the blood-vessels. A series of ten rabbits received daily injections of 2½ grains of adrenalin intravenously and a control series received the same injections with the addition of a subcutaneous injection of cholin (1 grain). The result was that the animals treated with adrenalin showed serious disease of the aorta, whilst those treated with cholin as well showed no lesions whatever. This observation is of the first importance, for some complaints have been made already that the protracted use of adrenalin has been followed by untoward after-effects. Experiments with other substances than cholin did not give such favourable results. Care must be taken to obtain pure cholin as it decomposes readily.

Three Cases of Renal Operations.

Dr. Fabricius recently demonstrated three patients and the very interesting preparations obtained from them. The first patient was a woman, aged 29 years, who had been operated upon several times for stone in the kidney; two stones had been removed successfully, when suddenly after an interval of six weeks of complete health septic fever supervened. In hospital accumulation or retention of pus was diagnosed and catheterisation of the ureter corroborated the diagnosis. But the patient was anxious to be freed from her pain and asked to have the kidney removed. This was done, and the kidney on section proved to be a mass of small abscesses. The incisions into the parenchyma of the organ had completely healed. The second patient complained of turbid urine and radiography proved the presence of an enormous "coral" stone in the kidney. During the operation all the pyramids of the organ became detached from each other, so that after extraction of the stone the kidney consisted of several separate lobes. Nevertheless, the patient made a good recovery, although the stone is one of the biggest that have been removed without extirpation of the organ. A portion of the cortical substance of the kidney had to be removed. The stone had completely filled the

Both inguinal and cervical glands were enlarged and there were condylomata. Weight on admission, 11 stones 10 pounds. Oct. 7th: The patients had had three injections of arsacetin (21 grains). The rash showed undoubted signs of improvement, the papules were smaller and less bright in colour, and there was a very marked general improvement. He looked much better, the headache had gone, and the pustules on the scalp were drying up. Oct. 14th: The patient had had seven injections (49 grains). The improvement was most marked, the rash had almost disappeared, the scalp was quite normal, and all signs of condyloma had gone. Oct. 21st: 70 grains of arsacetin had been injected. All symptoms had subsided and the patient's general health and appearance had improved out of all recognition and he was discharged to duty. One could hardly have looked for such a rapid recovery in a case which on admission threatened to be a very severe one and I have seldom seen a better result.

CASE 19.—Private ——, Irish Guards, was admitted to hospital on August 28th. He then had a large ulcerating sore involving the frænum, the glans, and part of the prepuce. The base of the ulcer was indurated. He also had a bright red roseolar eruption on the chest, the abdomen, and the back, and a few scattered papules. There was a large indurated gland in the left groin. The patient's weight was 12 stones. Oct. 7th: The patient had had four injections of arsacetin (28 grains). The rash showed signs of fading and the patient looked better. The sore had healed. Weight, 12 stones 3 pounds. Oct. 14th: The patient had had seven injections (49 grains). There was a very marked improvement, the rash had quite disappeared in some places, and where it was still present it was much less bright in colour. Weight, 12 stones 4 pounds—a gain of four pounds. Oct. 21st.: The patient completed a course of arsacetin of which he had had 70 grains. All active symptoms had disappeared and his general health and appearance had improved much—in fact, his health was excellent.

CASE 20.—Private ——, Irish Guards, was admitted on Sept. 23rd suffering from phimosis, œdema of the prepuce, and marked induration at the tip of the prepuce. There was a well-marked maculo-papular eruption on the chest, the abdomen, and the back. The lymphatic glands of the groin were somewhat enlarged, as also were those of the neck. The patient's weight was 10 stones 4 pounds. The patient was circumcised on Sept. 30th. The prepuce was found to be very hard and indurated, especially the lower part. Oct. 7th: The patient had had three injections (21 grains). The rash was fading and the patient had gained three pounds in weight, which now was 10 stones 7 pounds. Oct. 14th: The rash had almost completely gone except for a few yellowish spots in the flank. The circumcision was healing up and the lymphatic glands were less indurated. Oct. 21st: 70 grains of arsacetin had been injected and all the above symptoms had gone. The patient's health and appearance were excellent and he was discharged to duty.

CASE 21.—Private ——, 1st Scots Guards, was admitted to hospital on Oct. 9th. There was no history of a primary sore and there was no sign of one but he had been in hospital in September last for balanitis. He now had a well-marked pigmented eruption on the lower part of the abdomen, the thighs, the buttocks, and the legs. The rash had probably been on the body for some time. The tonsils and the throat were congested and there was a tendency to mucous patches. Both the inguinal and cervical glands were indurated. Weight on admission, 11 stones 2 pounds. Oct. 14th: The patient had had three injections (21 grains). The rash was clearing off considerably except for a few pigmented spots on the thighs. Weight, 11 stones 4 pounds, a gain of two pounds. The throat was much better. Oct. 21st: Six injections of arsacetin had been administered (42 grains). The rash had gone, the throat had healed, and the general appearance was good.

The Preparations Used.

Soamin.—Of the preparations used soamin was employed in 26 of the above cases. As already described in the paper quoted above, soamin is a para-amino-phenyl-arsonate having the formula $C_6H_4NH_2ASO(OH)(ONa)5H_2O$—in fact, it approximates very closely to the original preparation atoxyl. It has the advantage over the latter in that its purity can be assured. As will be seen, all these 26 cases had their full course of soamin which consists of a total of 100 grains and in only two were there the slightest bad effects (Cases 15 and 16); both as recorded showed slight toxic symptoms after they had had their eighth injection. The fact that the patients concerned were over 50 years of age might possibly account for the effects.

Arsacetin.—Eight of the series were treated with the arylarsonate known as "arsacetin" recommended by Ehrlich, as also by Professor Neisser; it is a sodium acetyl-phenyl-arsonate. $(C_6H_4NHCH_3CO).AsOOHONa$ = arsacetin. Professor Neisser says of it: "1. The preparation is certainly far less toxic than the old atoxyl, both healthy and diseased animals tolerating very much larger doses of arsacetin than of atoxyl. 2. As far as it is possible to make any comparison as to the remedial action on syphilis he thinks there is no doubt but that everything favours arsacetin. 3. No decomposition of any kind in the solution, even when stored for a long time, could be detected, nor does boiling daily alter the solutions in any respect." At Rochester Row in the above cases I have been giving 40 minims of a 15 per cent. solution every second day, this is equal to seven grains of arsacetin. The preparation can be employed in either a 10 per cent. or a 15 per cent. solution. The latter has the advantage that it does not require the injection of so large a quantity of fluid and consequently the temporary painfulness in the locality of the injection is slighter; there is, however, this disadvantage that the 15 per cent. solution deposits the salt when cold, so that before use it is necessary to heat it to bring it into solution again.

Comparison of the salts.—It is hard to give a definite opinion, at present, as to which of these two arylarsonate preparations is the most efficient owing to one's limited experience as regards arsacetin; at the same time one cannot help being very much struck by the remarkable results one has seen following its use in the cases treated, and it certainly possesses undoubted advantages over soamin, in that its solutions do not decompose; hence it is unnecessary to make them up fresh daily as is the case with soamin.

Conclusion.—The good results obtained from the use of arylarsonates in this further series of cases go to strengthen one's conviction that in them we possess a second specific for syphilis, at least from a preventive and remedial point of view. As regards the former I have at present ten cases under observation which were originally admitted with what were in my judgment undoubted primary lesions of syphilis, and in seven of which the spirochæta pallida was demonstrated; these cases underwent courses of soamin, varying from between 60 and 100 grains, and have now been all closely observed every week during the last ten months without developing any further sign of syphilis. From the remedial point of view the good results of these 34 cases speak for it. But as a curative agent it is beyond us at present to give a positive answer to this all-important question; time and clinical experience alone will enable us to do so; nor can this be done until it is proved without doubt that arylarsonates are capable of permanently expelling the spirochæta pallida from the system, as indicated by the patient being rendered capable of reinfection. Neisser's successful experiments on apes from this point of view justify us in hoping for this end. Until the question as to the capability of arylarsonates bringing about a permanent cure is fully established (which it is hoped Wassermann's serum test will be able to tell us for certain), I consider that after a course of arylarsonates mercury should be given, and for this purpose, after my patients have completed a course of arylarsonates, I put them on intramuscular injections of metallic mercury.

Military Hospital, Rochester-row.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—A meeting of this society was held on Nov. 20th, Dr. F. de Havilland Hall being in the chair. The list of sickness claims examined by the committee was a long one, and as is usual at this time of the year showed signs of rapidly growing. On the whole, however, the sickness business of the autumn has been favourable to the society and has worked off a good proportion of the loss that was sustained in the spring. The list of "chronics," that is, of permanently disabled members, continues to grow and more than £4000 a year are now being disbursed in respect of them. A large special reserve will be made for these at the approaching valuation of the society's business. Prospectuses and all further particulars can be had on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

profession of medicine. That improvement was apparent o anyone who recalls the conditions of professional life—ducational, ethical, and social—that prevailed in an earlier generation. In a word, the Council is by its nature progressive, and it makes for progress in other bodies. It is he concern of the nation as well as of the profession that ts advance should be encouraged, whether by the removal of hindrances or by the bestowal of further powers. On the work it has succeeded in accomplishing, notwithstanding its estrictions, it may well rest its claim to be intrusted with better equipment and a freer field of action. Of its original members, which included leaders in medicine like Brodie, Watson, Green, Acland, Syme, Corrigan, Clark, Hastings, Lawrence, Christison, Stokes, and others, none now survive. Of those who joined the Council towards the end of ts second decade we have lost Sir James Paget, Sir John Simon, Dr. Samuel Haughton, and within the last few weeks Sir Henry Pitman, after he had passed the hundredth year of his life of honourable and honoured service. But happily we are still able to greet their esteemed comrades, Sir William Turner, our only remaining past President; Mr. Pridgin Teale, whom lately his own county of York delighted to honour, as he is honoured wherever he is known; and Lord Lister, *non nobis solum sed toti mundo natus*, the glory of British medicine and the benefactor of the human race. To be colleagues or successors of such men, and of many whom time fails me to enumerate, may well make us, as members of this Council, both proud and earnest—proud that we are privileged to carry on their work; earnest, when we reflect on the responsibility that privilege implies. To the dead and to the living alike we are debtors, for their ideals and for their example. Besides Sir Henry Pitman, there has recently passed from us, in a green old age, Sir John Banks, the most genial of courtly physicians, whose native brilliancy and humour made him an ever-welcome colleague. And we have also to mourn the sudden but assuredly not untimely death of one who, seven years ago, was still our faithful and deeply respected fellow-worker, Dr. James Grey Glover. His intellectual candour, his strong faith in God and man, his courtesy, and his capacity for friendship made him an admirable representative of the practitioners of England. They chose wisely when they chose a man like him to be their spokesman; the Council was the better for his presence, and the richer for the 15 years of his strenuous activity on its behalf.

Of changes in our present membership I have only one to mention. The University of Cambridge has appointed Sir Clifford Allbutt to the seat which I had the honour to occupy from 1889 onwards. His fame and the great place he fills in our profession are known to all of you. But as a colleague who for many years served with him in the medical faculty of Cambridge, and always on the happiest terms of comradeship, I may be allowed to bespeak for him a special welcome. His personal qualities of mind and bearing will speedily procure him your friendship, as his work has already procured your admiration. On another member, hitherto known to us as Mr. Power, His Majesty has been pleased to confer the Knight Commandership of the Order of the Bath, in recognition of his eminent services to the public health. His work as an investigator, an administrator, and a counsellor of the Government and of the people of this country has been unsparingly rendered, often at the cost of his own health, and it has been singularly effective and fruitful. The mark of Royal favour which he has now received was never more worthily bestowed. The Council will join with the profession at large in congratulating Sir William Henry Power on his promotion and in wishing that in greater freedom from official cares his strength may be renewed for further service to the State.

His Majesty has also done special honour to two members of the Council, Dr. James Little and Dr. David White Finlay, by appointing them to be his Honorary Physicians in Ireland and in Scotland respectively. This recognition of the professional position they have gained by their attainments and their personal worth will be heartily approved by the Council. Lastly, it is my duty humbly but gratefully to acknowledge the gracious act of the King with reference to your President, who, happening to occupy this chair on the occasion of the Council's jubilee, has been favoured by the bestowal of a decoration. The Council will, I am sure, appreciate the honours which have been accorded to it and to its members by the Sovereign, esteeming them as an indication of His Majesty's approbation for their efforts to carry out loyally the duties laid upon them by the State, and of His Majesty's desire to encourage all who participate in the Council's work to persevere in their endeavours for the public good. At the present session several questions of national importance, which have been submitted for our consideration by the Lord President of the Privy Council, will be dealt with. The dangers arising from the administration of anæsthetics by untrained or unqualified persons have recently received public attention. A Bill has been proposed for the purpose of obviating some of these dangers; but it contains certain provisions which appear, to me at least, to be questionable, and on these I have ventured on your behalf to make communications to the authorities during the recess. The Executive Committee will have a report to lay before you on the subject.

We have also received for information the Nurses' Registration Bill and the Tuberculosis Prevention (Ireland) Bill, which have lately been under the consideration of Parliament. Each contains clauses referring to this Council on which it behoves us to express our opinion or to give instructions to our officers as to the advice which should be tendered to Government on the questions raised. The Medical Companies Bill has made no progress in the House of Commons during the autumn. Another measure affecting the Council has passed into law during the current session of Parliament. By the Irish Universities Act, which received the Royal Assent on August 1st, provision is made for substituting two new universities in the place of the Royal University of Ireland. Under Section 11 each of the two new Universities is empowered to hold qualifying examinations in medicine, surgery, and midwifery, as if it had been in existence at the passing of the Medical Act, 1886. Moreover, the governing body of each University is entitled to choose one representative to be a member of the General Council, in the place of the single representative of the Royal University. The graduates of the latter University, medical and other, are distributed, according to rules laid down in the Act, between the new universities. These are to have their seats in Dublin and Belfast respectively, and each will from the outset possess a numerous constituency of medical graduates already registered. I may add that your President's name is included in the Act as a commissioner for the University at Belfast, as is also the name of President Windle, lately the chairman of our Education Committee, as a commissioner for that at Dublin. The duty of the commissioners is to frame statutes for the general government of the new universities, and includes the duty of regulating the conditions of admission to medical and other degrees. By the friendly assistance of the Colonial Office and of the Foreign Office a large mass of authoritative information has been obtained respecting the laws regulating the practice of medicine, and the restrictions imposed on unqualified practitioners, throughout the empire and in foreign countries. This information, which reached the Council's office in various forms and in numerous languages, has been carefully analysed and digested by the Registrar and his staff for the use of the Committee on the Prevention of Unqualified Practice. As it is entirely derived from official sources the digest will be of value to the public, and when it has served the immediate purpose of the committee it will be well to issue it as one of the Council's publications. To the best of my knowledge no digest at present accessible surveys so fully and so authentically the existing laws of the civilised world in relation to medical practice. His Excellency the Governor of Bombay has invited me to attend, as his guest, a medical congress convened by him to meet at Bombay in February next and to deliver an address at a general assembly of the congress. In view of the movement which is on foot towards the better regulation of medical qualification and practice in India I should have been glad if it had been possible to accept the invitation. But the exigencies of work here and in Glasgow forbid so long an absence from home as would be necessary and I have had regretfully to decline.

An important declaration of the law, this time by judicial not by legislative authority, has been pronounced with reference to the Dentists Act. The Lord Chief Justice, with Mr. Justice Bigham and Mr. Justice Walton, have, in an appeal against the conviction of an unregistered practitioner of dentistry, decided that certain words (e.g., "painless extraction") employed by him in an advertisement were sufficient to bring him within the terms of Section 3. The words were held in effect to be a statement that the advertiser was were withdrawn and introduced into equal volumes of melted agar and plates poured; after 24 hours' incubation at 37° C. the colonies which had developed were counted and thus the numbers of organisms present in equal volumes of Tubes *a* and *b* and in equal volumes in Tubes *c* and *d* ascertained. The several tubes were then incubated at 37° C. and by means of the loop equal volumes were withdrawn at the same intervals, plates made, and colonies counted as before. The results are set out in Table VIII.

It is very evident that not only do the organisms die off more slowly in the first few hours in the nasal mucus than they do in the salt solution but also that after multiplication has begun they also increase more rapidly in the mucus than in the salt solution, conclusive evidence that not only is nasal mucus neither bactericidal nor inhibitory but also that it is actively nutrient. The obvious inference therefore is that the rôle of nasal mucus is purely a mechanical one to wash away the rapidly growing organisms—its action therefore is exactly that which Eyre has demonstrated that of the lacrymal secretion to be.

Site of formation of opsonins.—Wright, Bulloch, and others are agreed that opsonins are not elaborated in the blood and probably not in the blood-forming organs. That they are elaborated in the muscles and subcutaneous tissues is rendered probable by the following experiments which show that the opsonic index of muscle plasma to various organisms is considerably higher than that of the blood plasma. A human leg was obtained immediately after amputation and perfused through the popliteal artery with normal saline solution until this returned quite clear through the veins. The muscles were then dissected out, dried with filter paper, minced, cooled in an ice chest, and the muscle plasma extracted in a press. The very earliest portion was rejected as being obviously diluted with the saline solution used in the perfusion. The latter portions were collected and the index towards bacillus tuberculosis, bacillus of Friedländer, and staphylococcus albus was compared with that of the patient's blood serum. The results obtained are set forth in the following table:—

TABLE IX.

Experiment 1.

Bacillus tuberculosis.

Muscle plasma.	Human blood serum.
115 in 100 polymorphonuclear cells.	84 in 100 polymorphonuclear cells.

Index = 1·4.

Experiment 2.

Bacillus of Friedlander.

Muscle plasma.	Human blood serum.
112 in 100 polymorphonuclear cells.	90 in 100 polymorphonuclear cells.

Index = 1·24.

Experiment 3.

Staphylococcus albus.

Muscle plasma.	Human blood serum.
427 in 50 polymorphonuclear cells.	324 in 50 polymorphonuclear cells.

Index = 1·3.

Some slight allowance must also be made for the inevitable admixture of the muscle plasma with the saline solution. This only accentuates the difference, marked as it already is. It would thus appear that the muscle tissues contain a fluid with higher opsonic power than the blood plasma and may therefore be a site of opsonic formation. These results were confirmed by comparison of the opsonic powers of the muscle plasma and blood serum of animals towards various organisms.

These experiments render the view probable that when a vaccine is injected subcutaneously the opsonin is elaborated in the immediate neighbourhood of the site of injection and thence finds its way into the general circulation. Assuming, then, the accuracy of these observations upon the local formation of opsonins and the action of nasal mucus the processes of infection and the reactions thereto may be explained as follows.

Tissue metabolism and so opsonin formation go hand-in-hand with blood-supply. The nose is infected by organisms in a state of dormant activity. A draught striking, say, the back of the neck affects the vaso-motor nerves, causing constriction of the vessels of the nasal mucosa, and a resultant diminution in tissue metabolism and opsonin-formation. The organisms are thereby lighted up into activity and a cold begins. The protective mechanism of the body is now called into play, vaso-constriction is followed by vaso-dilatation, with consequent hyperæmia and increase in tissue metabolism. The result of this is rise in the local formation of opsonin and increased activity of the mucous glands, with consequent destruction and washing away of the infecting organisms. This process may be complete, in which case the cold rapidly gets well, or it may prove insufficient, in which case the cold progresses to a subacute or chronic state only to get well when the organisms have lost their virulence or been gradually destroyed.

VII.—TREATMENT.

(*a*) *Of acute colds.*—The best form of treatment is, as always, prevention—and much can be done in this direction both by the sufferer and by others; by the former by clearly realising that a cold carelessly communicated to others may prove a death-blow. It therefore behoves him to regard himself as an infectious case and take above all every possible care not to come into contact unnecessarily with anyone to whom a cold may be a serious matter, such as an old infirm person or anyone infected by chronic bronchitis or advanced heart disease. Infected handkerchiefs should be sterilised as soon as possible; this can easily be done by occasionally sprinkling them with a drop or two of formalin carried in a small bottle; and on no account should a sneeze be allowed to disperse organisms throughout a room but should be received into a handkerchief. It is his duty to avoid crowded rooms and public meetings, for his own sake as well as that of others, whenever possible; he should remain in his own room during the acute coryzal stage and adopt efficient means of cure.

The non-sufferer can do much to ward off attacks; in fact, I would go so far as to say that no one has any business to catch a cold except through sheer mischance. Due attention is paid daily to the toilet of the surface of the body, and even to that of the teeth; surely the nose should receive equal attention, especially in the atmosphere of crowded cities? To this end the nose should be douched each night at bed-time and if agreeable each morning on rising with a weak warm alkaline antiseptic solution; nothing is better for this purpose than glycothymoline or thymoglycin one part to three or four parts of warm water. This procedure is very efficient: numerous cases which formerly were perpetually catching colds have become almost immune to their attacks by the adoption of this simple precaution. At the first symptom of an approaching cold the nose should be douched and the throat gargled. Should these precautions have been omitted or have proved inefficacious and a cold have matured other means of combat must be employed.

In practice, my first procedure is to take cultivations from the nose upon blood serum and blood agar for next day's identification. It is through the vaso-motor system that the disease can in the early stages be best attacked. Accordingly the feet should be placed in hot mustard and water and the patient put to bed in a warm but thoroughly well ventilated room.

If nasal douches be employed in the acute coryzal stage—and I do not think they should—they must be used with great care to prevent increasing the chances of extension to the Eustachian tube and accessory sinuses; the simple device of placing the palm of the hand firmly over the external auditory meatus when expelling the mucus from the nostril will often suffice to prevent the dilatation of the corresponding Eustachian tube, and the consequent admission of infected material. In many subjects the tube of one side appears to be much more liable to infection than that of the other.

The diet, and especially the proteid, should be restricted, and particular attention paid to the bowels and kidneys; all cases of cold are constipated, and this must be carefully avoided. The excessive nasal discharge can be controlled by promoting free action of the kidneys and skin and can be much diminished by restricting the fluids taken. Whether this is strictly advisable, however, is rather doubtful in view of the mechanical action of the mucus upon the infecting organisms.

As regards drug treatment, this is largely symptomatic, but much reliance has been placed on solutions of quinine sulphate as a means of prevention or of shortening an attack; consideration of its actions will show that this is based probably upon analogy of its specific action in malaria.

to the comfort, happiness, and beauty of humanity. Dental surgery, he thought, warded off senility, because with a good set of teeth the better digestion of food was assured. He was not quite certain, however, whether after all Parr did not reach his great age owing to the fact that he had no teeth and was thus compelled to live on milk, of which possibly a good deal was sour, and Metchnikoff had pointed out the usefulness of the lactic acid bacillus in prolonging life by combating auto-intoxication. The proceedings, which were enjoyable throughout, closed with the toast of "The Chairman," proposed by Mr. John J. Andrew, President of the British Dental Association, a speech the kindly sentiments of which the chairman gracefully acknowledged. During the evening an excellent programme, comprising madrigals, glees, and catches, most of which were of the eighteenth century, was sung by the Frau Musika Vocal Quartette.

THE NATIONAL DENTAL HOSPITAL.—The students' annual dinner of this hospital was held at the Trocadéro Restaurant, London, on Nov. 20th, under the chairmanship of Sir William Henry Allchin, who, in proposing the toast of "The Hospital and School," said that though the qualification of L.D.S. was excellent in all respects, still, if it were possible for dentists to hold a general medical qualification it would be to their advantage because then there could be no question as to the propriety or otherwise of dental surgeons administering an anæsthetic. Further, it seemed to him that if every dentist qualified in general medicine and surgery it would add much to the collective dignity of the profession. Mr. P. S. Spokes, the dean of the school, in the course of his reply to the toast, said that in regard to additional medical qualifications, if everyone had the time and money at his disposal then he thought that everyone should, before applying himself to the dental profession, finish his medical training. He claimed, however, that men who passed the L.D.S. were able dental surgeons and well fitted for their work. Other speakers included Mr. A. Pearce Gould, Mr. K. W. Goadby, and Mr. C. W. Glassington.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The annual meeting of the British Medical Temperance Association was held in the rooms of the Medical Society of London on Nov. 20th, the attendance being good. The President, Professor G. Sims Woodhead, occupied the chair, and among others there were present Dr. V. H. Rutherford, M.P., Surgeon-General George J. H. Evatt, C.B., Dr. Heywood Smith, Dr. T. N. Kelynack, Dr. G. B. Basil Price, Dr. E. Claude Taylor, Dr. R. Leslie Ridge, and Dr. C. F. Harford. The President paid a warm tribute to the services of the late Dr. J. J. Ridge who had acted as honorary secretary of the association for 32 years. A discussion followed on the future work and aims of the association in which many spoke. The policy outlined was that the association should be strictly medical and non-political, working for the advancement of knowledge of the medical and scientific side of the alcohol problem. It was announced that the *Medical Temperance Review* would be continued and published quarterly. The association has 671 members and 237 student associates.

THE Prussian Academy of Sciences has granted to Dr. Gustav Fritsch £100 to enable him to publish a work on the area centralis of the human retina.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

THE Parliamentary session seems likely to be more prolonged than was anticipated when the autumn sitting began in October. The most sanguine estimates are that Parliament will be prorogued a few days before Christmas. However, if this confident anticipation is to be realised there must be a considerable acceleration of the rate of progress of the Ministerial programme of legislation. The House of Commons has still to deal with such important subjects as education, the miners' eight hours' day, and housing and town planning, and unless the Government abandons some of its Bills the statement that the session will extend into January seems well founded.

HOUSE OF COMMONS.

THURSDAY, NOV. 19TH.

The International Commission on Opium.

Mr. THEODORE C. TAYLOR asked the Secretary of State for Foreign Affairs what were the terms of reference of the International Commission on Opium which was to meet in Shanghai in January next, and whether the inquiry would cover the use of morphine and cocaine.—Mr. MCKINNON WOOD (on behalf of Sir EDWARD GREY): The terms of reference are still under consideration and they will be communicated to the honourable Member as soon as they have been definitely settled.

The Grants to County Infirmaries in Ireland.

Mr. O'DOWD asked the Chief Secretary to the Lord Lieutenant of Ireland whether any portion of the grant given by a county council to a county infirmary could be applied towards the maintenance of a separate institution for tuberculous patients.—Mr. CHERRY (the Attorney-General for Ireland) replied on behalf of Mr. BIRRELL: The reply to this question is in the negative.

Hop Substitutes in the Manufacture of Beer.

Answering Mr. SUMMERBELL Mr. ASQUITH said: I understand that my right honourable friend the Chancellor of the Exchequer will shortly introduce a Bill to prohibit the use of hop substitutes in the manufacture of beer.

Tuberculous Milk in London.

Mr. ELLIS DAVIES asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, whether his attention had been drawn to the fact that out of 92 samples of milk sampled by the officials of the London County Council last week 23·9 per cent. were found to be tuberculous; and what steps, if any, the Government proposed to take to deal with the disease.—Sir EDWARD STRACHEY replied: The Board has seen a copy of the report of the Public Health Committee of the London County Council to which my honourable friend is perhaps referring. It would appear that the samples examined were taken at various times during the last quarter. The Board is carefully considering whether it can take any action to deal with the matter.

MONDAY, NOV. 23RD.

Petrol Accidents.

Mr. PERCY BARLOW asked the Secretary of State for the Home Department whether his attention had been called to the frequency of accidents involving loss of life and personal injuries arising from the ignition or explosion of petrol and other vapours; and whether he was prepared to take any, and if so what, steps to ascertain whether any means existed of preventing such accidents.—Mr. GLADSTONE answered: I have had this matter under my consideration, and I hope shortly to be able to appoint a small committee to consider the question of the use of mechanical devices to diminish the dangers attendant on the storage of petrol spirit.

The Sale of Food and Drugs Act in Scotland.

Mr. VINCENT KENNEDY asked the Secretary for Scotland to state the numbers of samples taken under the Sale of Food and Drugs Act, or the corresponding Scotch Act, for the years 1905–06–07; how many prosecutions were instituted and with what result; and what was the average annual cost of working this department.—Mr. SINCLAIR replied: The number of formal samples examined by analysts on behalf of local authorities in Scotland for the years ended Sept. 30th, 1905, 1906, and 1907, and the number of prosecutions and the result of such prosecutions were as follows:—

	1905.	1906.	1907.
Number of samples	7221	7514	6842
Number of prosecutions ...	373	419	369
Number of convictions	300	328	282

No information is collected by the Local Government Board for Scotland regarding the annual cost of working the Sale of Food and Drugs Act.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ALLEN, R. W., M.B., B.S. Lond., has been appointed Clinical Pathologist to the Mount Vernon Hospital.

BAGGS, J. C., L.S.A., has been appointed Medical Officer to the Siamese Government at Tuket.

BOND, FRANCIS THOMAS, M.D. Lond., M.R.C.S., F.R.S. Edin., has been re-appointed Medical Officer of Health for the Gloucestershire Combined Sanitary District.

CLARKE, WALTER TRAVERS, M.R.C.S., L.R.C.P. Lond., has been appointed School Medical Officer for Morley, Yorks.

COOK, E. N., M.B., B.S., M.R.C.S., L.R.C.P., has been appointed House Surgeon at University College Hospital.

CORFIELD, CHARLES, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Dental Anæsthetist at the Bristol General Hospital.

ETTLES, WILLIAM, M.D., C.M. Aberd., F.R.C.S. Edin., has been appointed Pathologist to the Royal Eye Hospital.

GILL, JOHN WALLIS, L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer by the Liskeard (Cornwall) Board of Guardians.

GOUGH, WILLIAM, M.B., B.S., B.Sc. Lond., F.R.C.S. Eng., has been appointed Honorary Medical Officer to the Leeds Maternity Hospital.

at 60° C. This result was confirmed by repetition with two other specimens of serum as follows:—

Serum I.		Serum II.	
Unheated.	Heated.	Unheated.	Heated.
220 in 100	67 in 100	280 in 100	61 in 100

Just as in the former experiment we see that about a quarter of the opsonin for bacillus septus is not destroyed by heating for one hour at 60° C.

(c) Organism employed. bacillus of Friedlander.

Serum I.		Serum II.	
Unheated.	Heated.	Unheated.	Heated.
777 in 100	92 in 100	636 in 100	97 in 180

From this it would appear that about one-seventh of the opsonin for bacillus of Friedlander is not destroyed by heating at 60° C. for one hour.

One striking feature in the experiments (b) and (c) with heated serum is that only 1 cell in 10 or 20 exhibits phagocytic power and that it exhibits it usually to a very marked degree. A frequent experience in doing opsonic determinations even with emulsions of considerable dilution is to find a cell here or there crowded far above its fellows with organisms. The recurrence of this phenomenon in cases where heated sera are employed would suggest peculiar activity in certain few leucocytes, an activity which may be exerted upon organisms almost independently of the opsonising action of the serum.

B. *Experiment. Determination of length of negative phase.*—It is well known that the first result of the injection of a vaccine of any organism is the production of a so-called negative phase, or temporary reduction in the opsonic index to that organism; this period during which the negative phase lasts may be regarded as one of increased susceptibility or diminished powers of resistance, and varies not only for different organisms but also for different individuals. It therefore becomes a matter of great importance to gain some idea of its length in the case of these "cold" organisms, lest premature exposure of the patient to changes of temperature and cold should result in an increase in the severity of the attack and a possible pneumonia in the case of a Friedländer or paratetragenus infection.

(a) An injection of 250,000,000 of killed bacillus septus was given and samples of blood were taken on injection and after intervals of 3, 6, 12, 18, 24, 36, 48, 72, and 96 hours. The comparative opsonising powers of the various sera towards bacillus septus were then determined in the usual way with the following results:—

TABLE X.

1. On injection	......	882 bacilli in 200 cells	Index = 1
2. After 3 hours	......	544 „ „	„ = 0·62
3. „ 6 „	......	885 „ „	„ = 1·0
4. „ 12 „	......	804 „ „	„ = 0·91
5. „ 18 „	......	949 „ „	„ = 1·08
6. „ 24 „	......	1096 „ „	„ = 1·25
7. „ 36 „	......	1000 „ „	„ = 1·15
8. „ 48 „	......	1044 „ „	„ = 1·20
9. „ 72 „	......	1220 „ „	„ = 1·38
10. „ 96 „	......	1248 „ „	„ = 1·39

From this we see that at the end of three hours the negative phase is fully established, that the index has recovered to unity at the end of six hours, again to fall slightly at 12 hours, then to recover and gradually attain a maximum at about the end of the third day.

(b) *For micrococcus catarrhalis.*—

TABLE XI.

Injection = 350,000,000 organisms.

1. On injection	......	942 bacilli in 200 cells	Index = 1
2. After 3 hours	......	722 „ „	„ = 0·77
3. „ 6 „	......	580 „ „	„ = 0·62
4. „ 9 „	......	825 „ „	„ = 0·88
5. „ 15 „	......	1125 „ „	„ = 1·20
6. „ 22 „	......	1080 „ „	„ = 1·15
7. „ 28 „	......	1131 „ „	„ = 1·20

Here we see that the negative phase lasted somewhere between nine and 15 hours, say about 12 hours. This experiment, as in the case of the one with bacillus septus, was done upon myself when quite free from cold. The following observation was made upon a patient who had been troubled with a bad tracheal cough for a fortnight, from whose tracheal mucus the micrococcus catarrhalis had been recovered in practically pure culture.

TABLE XII.

Injection=350,000,000 organisms.

Normal serum*	... ...	250 bacilli in 100 cells ...	Index 1
Patient's serum	before injection ...	140 „ „ ...	„ = 0·56
„ „	after 4 hours ...	90 „ „ ...	„ = 0·36
„ „	„ 8 „ ...	220 „ „ ...	„ = 0·88
„ „	„ 12 „ ...	280 „ „ ...	„ = 1·12
„ „	„ 15 „ ...	312 „ „ ...	„ = 1·25
„ „	„ 18 „ ...	325 „ „ ...	„ = 1·30

TABLE XIII.

The Opsonic Index during an Acute Attack due to Bacillus of Friedländer.

Third day of cold. Cold began on 16th inst. Index before attack 1·25.

2 P.M.	18th	... ...	Index = 1·17
11 „	18th	... ...	„ = 1·05
10 A.M.	19th	... ...	„ = 1·26
10 P.M.	19th	... ...	„ = 1·07
10 A.M.	20th	... ...	„ = 1·07

The subacute stage began on the 20th.

4 P.M.	24th	... ...	Index = 0·96
Noon	26th	... ...	„ = 0·89
„	27th	... ...	„ = 0·93

Injected with 300,000,000 at 2 A.M. on the 28th inst., as the subacute stage had become distinctly annoying to the patient.

2 A.M., 28th, before injection	... ...	Index = 0·87
After 8 hours ...	... ...	„ = 1·9
„ 18 „	... ...	„ = 2·14
„ 32 „	... ...	„ = 2·4

Nose quite sterile and cold perfectly well.

In another case the negative phase lasted over 24 hours.

From these experiments we learn that the duration of the negative phase does not usually last over 12 hours. If, therefore, a patient be injected in the evening, remain in the house, and go to bed early, risk of a fresh acute attack being lit up should be over by the time of rising in the morning; for even if the positive phase be not fully established the index is then on the rise, and a period of rising index is probably one of slight danger of infection.

(c) *Preparation of the vaccine.*—It is well recognised that to obtain the best results it is advisable to prepare the vaccine from the organisms isolated from the person's own body. In the case of tubercle this is hardly possible, while in gonorrhœal affections it is not always easy, nor does it seem so imperative for two reasons: firstly, the gonococcus seems to be a bacteriological entity and not to be a member of a family; and, secondly, in chronic affections it may be of so much diminished virulence that a vaccine prepared from a fully virulent strain may be the more advantageous to employ. The bacillus septus and micrococcus catarrhalis also appear to be bacteriological entities, but so easy is their isolation, and consequently the preparation of a vaccine, that unless the case is one urgently calling for injection, when a stock vaccine may be employed, I consider the preparation of one from the patient's own organisms the better procedure. The case of the bacillus of Friedländer stands on quite a different footing. This appears to be not a single organism but to be a generic term for a number of very closely related bacteria, exhibiting, it is true, the same morphological appearances and general cultural reactions but varying slightly in behaviour towards the various sugars. In Table XIV. this is set forth for the nine strains isolated from nine of my cases. It will be remembered that these were proved highly pathogenic to rabbits, guinea-pigs, and rats. My best thanks are due to Dr. J. W. H. Eyre for confirming these reactions.

No. 3 is of special interest inasmuch as it was isolated from a chronic cold of which the acute attack was almost certainly communicated by No. 1. Shortly after the culture was taken the patient was well and the question is whether the changed reactions are due simply to diminished activity or to changes of environment.

Comparison of sugar reactions.—It will be seen that the only absolutely constant results as regards the formation both of acid and gas for all nine strains were obtained in the cases of glucose, levulose, and galactose. In the instances of all the other sugars slight variations are seen. Strains 1,

Notes, Short Comments, and Answers to Correspondents.

QUEEN ANNE'S PHYSICIANS.

IN "Queen Anne and Her Court," by Mr. P. F. W. Ryan, recently published by Messrs. Hutchinson and Co., there is much to interest medical readers. The work consists of a series of splendid portraits of the men and women—the *dramatis personæ* of one of the greatest dramas of English history. Here is the author's description of Dr. John Arbuthnot and his quarters in St. James's Palace:—

> "Passing through the darkening galleries and cloisters one comes to a remote wing of the palace, where in dingy quarters a gentleman of forty, pleasant of face, with a humorous twinkle in his eye, kept his Court amongst his books. This evening he is less serene than is his wont. His apartment has somewhat the air of discomfort one associates with unusual preparations. Everything here is too trim, too mathematical to please John Arbuthnot. His books have been dusted and disarranged. His easy chair is in rebellion; they have made it look formal; it is at the angle of irritation with regard to the light, and he can neither rest his feet on the mantelpiece nor on the table. One must make sacrifices for one's friends or lose them; and John Arbuthnot, physician extraordinary to Queen Anne, was not a curmudgeon to grumble because his rooms were uncomfortably neat to receive Her Majesty and a wedding party. Yes, a wedding party, no less; and for a secret wedding, too. Death and damnation! If people would marry why not by daylight; or if by candlelight, why not in their own rooms!
>
> Arbuthnot was not only a physician, he was a man of wit and learning and as cheerful as he was gifted. Swift said of him that he was the first wit in London and Pope celebrated his medical skill in the lines:—
>
> 'Friend to my life, which did not you prolong
> The world had wanted many an idle song?'
>
> His rooms in St. James's were the resort of every pleasant fellow employed at Court, and of all the wits of the town. Thither they made their way of an evening from the theatres and coffee-houses to play at cards and punish a bottle while discussing the latest book, or pamphlet, or comedy. They did justice to the scandal of the hour and when fresher topics flagged it was always easy to poke fun at the Queen above the Queen—Her Majesty, Sarah."

Then follows a most amusing description of the secret wedding of Abigail Hill and Captain Masham, the Queen stealing on tip-toe to the ceremony in mortal terror of being caught by her arch enemy and tyrant Sarah, Duchess of Marlborough.

Speaking of Dr. Radcliffe the author says: "He was the first of his profession and a high Tory, with little love for princes or princesses who owed their dignities to the Revolution. Radcliffe offended Anne by declining to hasten to St. James's Palace when she imagined she needed his presence. 'Tell Her Highness,' said Radcliffe, 'nothing ails her but the vapours.'" He was summoned to the death bed of Anne's son, the young Duke of Gloucester. On being told that the patient had been bled he replied that they had destroyed the Prince. "You may finish him," he said, "I will not prescribe." It was Radcliffe who, when summoned to the bedside of William III., looking at the King's swollen legs said, "I would not take your two legs for your three kingdoms." The well known story of the encounter between Radcliffe and the great painter Sir Godfrey Kneller bears re telling. They were good friends and to facilitate their friendly intercourse a door was put into the wall that separated their two gardens in Kensington. But the doctor's maids stole the painter's flowers. The painter then sent a note saying that he would take the door away and brick up the aperture. To this the doctor replied that he might do anything he liked to the door, except paint it. Kneller responded that he was willing to take anything from Dr. Radcliffe, except his physic.

"THE HUMAN WOMAN."

WE cannot publish much of the correspondence which we have received arising out of our editorial remarks of last week upon Lady Groves's recent work with this title. Lady Groves's work puts forward the arguments on her side. We have expressed our views on them frankly, but we do not claim to have settled the whole of a difficult question. Most of the points at issue are before our readers and they must make up their own minds.

THE NEED OF MEDICAL MEN IN CHINA.

IN his annual report, just received at the Foreign Office, Sir Alexander Hosie, acting commercial attaché to the British Legation at Peking, observes that "at a time when the Chinese Government has made up its mind to eradicate the opium habit, China requires the services of thousands of medical men to help the people who are smokers to rid themselves of the craving for the drug, and she does not possess them. She also requires their services to diminish the tremendous infant mortality of the country and to remedy those insanitary conditions to which much of that mortality is due. It is true that there are medical colleges in Hong-Kong and in several cities of China, but their graduates are merely a drop in the ocean of the Empire's requirements." In another section of his report, dealing with imported medicines, Sir Alexander Hosie states that Japanese goods take the lead, British coming second. The Japanese importers aim at reaching the poor in China by making up their medicines in small doses, with labels in Chinese setting forth the methods of use and the diseases which they are intended to cure.

GARBAGE-MONGERS AT WIGAN.

AT the Wigan borough police court on Nov. 19th two hawkers were summoned for being in possession of 27 pieces of diseased meat for the purpose of sale and intended for the food of man. Evidence was given that the meat was "unsound, diseased, and as soft as rags, and not fit for human food." The defendants did not appear and a warrant was issued for their arrest. Another case was heard by the Wigan justices on the following day in which Joseph Harrison was summoned for exposing for sale a forequarter of beef which had tubercles on the pleura; the beef was condemned and destroyed. Although clear evidence was given by the medical officer of health as to the diseased condition of the meat and the danger to the community caused by the sale of tuberculous meat, evidence which compelled the bench to acknowledge the case as proved, the defendant was let off on payment of the costs only. It would be interesting to know if this leniency was the result of the arguments of the defending solicitor who adduced Professor Koch's views on bovine tuberculosis and also suggested that "the highest authorities contend that although there is a slight tuberculosis in meat it is all the better for the consumer."

METRIC SYSTEM.

To the Editor of THE LANCET.

SIR,—I observe that you notice in THE LANCET of Nov. 14th a new invention entitled the "Versimetric" Chart which is likely to be useful. This encourages me to write you these few lines to explain two little rules for converting the linear metric measures into approximate English equivalents, as follows. Take the denominators of the fractions of the metre which are tenths and call them ninths of a yard; thus, one decimetre equals one ninth of a yard, one centimetre equals one-ninetieth of a yard, one millimetre equals one-nine-hundredth of a yard approximately. As the yard is 36 inches and 36 is divisible by both 9 and 18, and 90 or 900 are both divisible by the same divisors and the latter by 36 also, it is easy to discover that a centimetre, or $\frac{1}{90}$th yard or $\frac{36}{90}$ equals $\frac{2}{5}$ inch and that a millimetre or $\frac{36}{900}$ equals $\frac{1}{25}$ inch. The metre itself approximately equals ten ninths of a yard (40 inches). The second rule is to multiply the number of centimetres by 4 and divide by 10, which simply means placing the decimal point to the left of the last figure of the product—e.g., 5 centimetres (multiplied by 4 and divided by 10) equal 2·0 inches; 12 centimetres (multiplied by 4 and divided by 10) equal 4·8 inches, and so on. To turn inches into centimetres multiply the number of inches by 10 and divide by 4—e.g., 6 inches (60 ÷ 4) equal 15 c.m. These rules will only apply to small measures.

I am, Sir, yours faithfully,

Nov. 16th, 1908.

F.

A HYGIENIC PRACTITIONER.

A PAMPHLET has been placed in our hands entitled "Are Medicines and Operations Necessary?" The author is one I. Brozel and the book, which is marked "No. 1 of Brozel's Hygienic Library. Tenth Thousand," is an impudent attack upon the medical profession as well as an invitation to the public to go to the writer "for advice and treatment, paying 10*s.* 6*d.* and 21*s.* per month."

STERILISATION IN HYPODERMIC INJECTIONS.

To the Editor of THE LANCET.

SIR,—In these days of hypodermic injections, can any of your readers suggest any way of quickly sterilising both the syringe and the liquid to be injected? Lysol and other irritant antiseptics added to the liquid and used to lubricate the piston of the syringe simply irritate the subcutaneous tissues so much as to make the patient sometimes refuse further treatment, while boiling the syringe for each patient causes much loss of time.—I am, Sir, yours faithfully,

Nov. 19th, 1908.

SYDNEY WHITAKER.

AN AFRICAN ANTIDOTE TO SNAKE POISON.

MR. J. P. Herbst, assistant resident magistrate at Rietfontein, Cape Colony, in a report on the large tract of land known as the Kalahari Desert, describing the natives of that region and their habits, observes that the personal possessions of a Bushman consist of a few lean and hungry dogs, a short but heavy knobkerrie, a long bone tsamma knife, a bow and arrows, the dried body of the "gnubo" snake as an antidote against snake-bite, a skin bag as a receptacle for these articles, and a tin for use as a kettle. The "gnubo" snake is very rarely found, spending most of its time underground. It is small, of a brown colour, and said to be very poisonous. There are two kinds—one with two small, short, fore-feet. The dried body is carried by all natives in the Kalahari district and in German South West Africa and the dried flesh, ground to a powder and rubbed into the incised wound, is said by all to be an absolutely safe antidote to the most virulent snake poison. It is said to draw the poison "out in a stream." Some "gnubo" was analysed in Cape Town some years ago but no properties were found that could account for this action.

at 60° C. This result was confirmed by repetition with two other specimens of serum as follows:—

Serum I.		Serum II.	
Unheated.	Heated.	Unheated.	Heated.
220 in 100 ……	67 in 100	280 in 100 ……	61 in 100

Just as in the former experiment we see that about a quarter of the opsonin for bacillus septus is not destroyed by heating for one hour at 60° C.

(*c*) Organism employed: bacillus of Friedlander.

Serum I.		Serum II.	
Unheated.	Heated.	Unheated.	Heated.
777 in 100 ……	92 in 100	636 in 100 ……	97 in 180

From this it would appear that about one-seventh of the opsonin for bacillus of Friedländer is not destroyed by heating at 60° C. for one hour.

One striking feature in the experiments (*b*) and (*c*) with heated serum is that only 1 cell in 10 or 20 exhibits phagocytic power and that it exhibits it usually to a very marked degree. A frequent experience in doing opsonic determinations even with emulsions of considerable dilution is to find a cell here or there crowded far above its fellows with organisms. The recurrence of this phenomenon in cases where heated sera are employed would suggest peculiar activity in certain few leucocytes, an activity which may be exerted upon organisms almost independently of the opsonising action of the serum.

B. Experiment. Determination of length of negative phase.—It is well known that the first result of the injection of a vaccine of any organism is the production of a so-called negative phase, or temporary reduction in the opsonic index to that organism; this period during which the negative phase lasts may be regarded as one of increased susceptibility or diminished powers of resistance, and varies not only for different organisms but also for different individuals. It therefore becomes a matter of great importance to gain some idea of its length in the case of these "cold" organisms, lest premature exposure of the patient to changes of temperature and cold should result in an increase in the severity of the attack and a possible pneumonia in the case of a Friedländer or paratetragenus infection.

(*a*) An injection of 250,000,000 of killed bacillus septus was given and samples of blood were taken on injection and after intervals of 3, 6, 12, 18, 24, 36, 48, 72, and 96 hours. The comparative opsonising powers of the various sera towards bacillus septus were then determined in the usual way with the following results:—

TABLE X.

1. On injection	……	882 bacilli in 200 cells	……	Index = 1
2. After 3 hours	……	544 ,, ,,	……	,, = 0·62
3. ,, 6 ,,	……	885 ,, ,,	……	,, = 1·0
4. ,, 12 ,,	……	804 ,, ,,	……	,, = 0·91
5. ,, 18 ,,	……	949 ,, ,,	……	,, = 1·08
6. ,, 24 ,,	……	1096 ,, ,,	……	,, = 1·25
7. ,, 36 ,,	……	1000 ,, ,,	……	,, = 1·15
8. ,, 48 ,,	……	1044 ,, ,,	……	,, = 1·20
9. ,, 72 ,,	……	1220 ,, ,,	……	,, = 1·38
10. ,, 96 ,,	……	1248 ,, ,,	……	,, = 1·39

From this we see that at the end of three hours the negative phase is fully established, that the index has recovered to unity at the end of six hours, again to fall slightly at 12 hours, then to recover and gradually attain a maximum at about the end of the third day.

(*b*) *For micrococcus catarrhalis.*—

TABLE XI.

Injection = 350,000,000 organisms.

1. On injection	……	942 bacilli in 200 cells	……	Index = 1
2. After 3 hours	……	722 ,, ,,	……	,, = 0·77
3. ,, 6 ,,	……	580 ,, ,,	……	,, = 0·62
4. ,, 9 ,,	……	825 ,, ,,	……	,, = 0·88
5. ,, 15 ,,	……	1125 ,, ,,	……	,, = 1·20
6. ,, 22 ,,	……	1080 ,, ,,	……	,, = 1·15
7. ,, 28 ,,	……	1131 ,, ,,	……	,, = 1·20

Here we see that the negative phase lasted somewhere between nine and 15 hours, say about 12 hours. This experiment, as in the case of the one with bacillus septus, was done upon myself when quite free from cold. The following observation was made upon a patient who had been troubled with a bad tracheal cough for a fortnight, from whose tracheal mucus the micrococcus catarrhalis had been recovered in practically pure culture.

TABLE XII.

Injection = 350,000,000 organisms.

Normal serum*	… … … … …	250 bacilli in 100 cells …	Index 1
Patient's serum	before injection …	140 ,, ,, …	,, = 0·56
,, ,,	after 4 hours …	90 ,, ,, …	,, = 0·36
,, ,,	,, 8 ,, …	220 ,, ,, …	,, = 0·88
,, ,,	,, 12 ,, …	280 ,, ,, …	,, = 1·12
,, ,,	,, 15 ,, …	312 ,, ,, …	,, = 1·25
,, ,,	,, 18 ,, …	325 ,, ,, …	,, = 1·30

TABLE XIII.

The Opsonic Index during an Acute Attack due to Bacillus of Friedlander.

Third day of cold. Cold began on 16th inst. Index before attack 1·25.

2 P.M.	18th	… … … … … …	Index = 1·17
11 ,,	18th	… … … … … …	,, = 1·05
10 A.M.	19th	… … … … … …	,, = 1·26
10 P.M.	19th	… … … … … …	,, = 1·07
10 A.M.	20th	… … … … … …	,, = 1·07

The subacute stage began on the 20th.

4 P.M.	24th	… … … … … …	Index = 0·96
Noon	26th	… … … … … …	,, = 0·89
,,	27th	… … … … … …	,, = 0·93

Injected with 300,000,000 at 2 A.M. on the 28th inst., as the subacute stage had become distinctly annoying to the patient.

2 A.M., 28th, before injection	… … … …	Index = 0·87
After 8 hours …	… … … … …	,, = 1·9
,, 18 ,,	… … … … …	,, = 2·14
,, 32 ,,	… … … … …	,, = 2·4

Nose quite sterile and cold perfectly well.

In another case the negative phase lasted over 24 hours.

From these experiments we learn that the duration of the negative phase does not usually last over 12 hours. If, therefore, a patient be injected in the evening, remain in the house, and go to bed early, risk of a fresh acute attack being lit up should be over by the time of rising in the morning; for even if the positive phase be not fully established the index is then on the rise, and a period of rising index is probably one of slight danger of infection.

(*c*) *Preparation of the vaccine.*—It is well recognised that to obtain the best results it is advisable to prepare the vaccine from the organisms isolated from the person's own body. In the case of tubercle this is hardly possible, while in gonorrhœal affections it is not always easy, nor does it seem so imperative for two reasons: firstly, the gonococcus seems to be a bacteriological entity and not to be a member of a family; and, secondly, in chronic affections it may be of so much diminished virulence that a vaccine prepared from a fully virulent strain may be the more advantageous to employ. The bacillus septus and micrococcus catarrhalis also appear to be bacteriological entities, but so easy is their isolation, and consequently the preparation of a vaccine, that unless the case is one urgently calling for injection, when a stock vaccine may be employed, I consider the preparation of one from the patient's own organisms the better procedure. The case of the bacillus of Friedländer stands on quite a different footing. This appears to be not a single organism but to be a generic term for a number of very closely related bacteria, exhibiting, it is true, the same morphological appearances and general cultural reactions but varying slightly in behaviour towards the various sugars. In Table XIV. this is set forth for the nine strains isolated from nine of my cases. It will be remembered that these were proved highly pathogenic to rabbits, guinea-pigs, and rats. My best thanks are due to Dr. J. W. H. Eyre for confirming these reactions.

No. 3 is of special interest inasmuch as it was isolated from a chronic cold of which the acute attack was almost certainly communicated by No. 1. Shortly after the culture was taken the patient was well and the question is whether the changed reactions are due simply to diminished activity or to changes of environment.

Comparison of sugar reactions.—It will be seen that the only absolutely constant results as regards the formation both of acid and gas for all nine strains were obtained in the cases of glucose, levulose, and galactose. In the instances of all the other sugars slight variations are seen. Strains 1,

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations (Mr. Carson). Clinics:—Surgical (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 4.30 P.M., Dr. S. J. Gilfillan: Demonstration of Cases of Mental Disease at the Colney Hatch Asylum.

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X Rays. 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Operations (Mr. W. Edmunds). Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Coccus Diseases: (1) Impetigo Contagiosa; (2) Furuncle; (3) Carbuncle; (4) Coccogenic Sycosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Dr. Buzzard: Myelitis.
FRIDAY.—3.30 P.M., Dr. Buzzard: Myelitis.

HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, Welbeck-street, W.

THURSDAY.—5 P.M., Dr. F. S. Palmer: Anterior Poliomyelitis.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Mr. Addison: A Demonstration on Selected Surgical Cases.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

TUESDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.).

THURSDAY (3rd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (5th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

years, involvement of one Eustachian tube; frequent exacerbations, at least six every winter.

Duration of treatment.—14 months.

Number of injections.—Three of Friedländer vaccine and two of tracheal organism.

Result.—Greatly diminished secretion of mucus from naso-pharynx and trachea. One acute attack during 12 months.

CASE 31 (still under treatment).—

Description.—Chronic nasal catarrh for 20 years with involvement of frontal and ethmoidal sinuses and of the left middle ear; repeated surgical operations; many exacerbations and acute attacks.

Duration of treatment.—Intermittent during nine months.

Number of injections.—Five.

Result.—Little improvement in the chronic condition, Friedländer's bacillus being still present. Increased bodily comfort and marked diminution of acute attacks, only one in the nine months.

CASE 34.—

Description.—Chronic tracheitis for years with exacerbation and rather frequent attacks of naso-pharyngeal catarrh.

Duration of treatment.—12 months.

Number of injections.—Three of tracheal organisms and two of bacillus septus and micrococcus catarrhalis.

Result.—Practical disappearance of excessive secretion of mucus with one slight exacerbation and one acute attack of cold due to the micrococcus catarrhalis in the 12 months.

CASE 42.—Chronic nasal catarrh for from 10 to 12 years with involvement of right Eustachian tube and middle ear; between exacerbations symptoms almost disappear.

Treatment.—Still progressing: one of bacillus of Friedlander, bacillus septus, and micrococcus catarrhalis; one of bacillus septus (own *organisms*); *one of* bacillus septus and micrococcus catarrhalis (own *organisms*).

Result.—Considerable improvement. No acute attacks during past six months.

2. *Acute Colds.*

(*a*) Those due to the bacillus septus.

CASE 8.—

Description.—Very subject to acute colds, especially upon undertaking a train journey, which always began with a sore throat and would appear to have been due to the bacillus septus.

Duration of treatment.—15 months.

Number of injections.—Two of bacillus septus alone and three of mixed organisms.

Result.—Only one attack during 15 months, but that a very severe one indeed and due to the micrococcus catarrhalis.

CASE 9.—

Description.—Sore throat, profuse nasal discharge, no cough. Bacillus septus isolated.

Treatment.—One injection of 250,000,000 organisms upon the fourth day.

Result.—Complete recovery within 48 hours and subsequent immunity during the whole winter.

CASE 17.—

Description.—Acute nasal catarrh beginning with sore throat; cough absent. Bacillus septus isolated. Patient very liable to such attacks which usually lasted for a month or more.

Treatment.—Injection of 275,000,000 organisms upon the third day.

Result.—Complete recovery within 48 hours without the presence of any subacute stage. Subsequent immunity for at least six months. The patient was not seen subsequently to that period; I heard that he then caught a severe cold but have no details.

CASE 30.—

Description.—An acute attack of nasal catarrh beginning with sore throat; *cough altogether absent.* This attack differed in clinical character to the usual ones in which sore throat was, as a rule, absent and persistent tracheal cough habitual. The bacillus septus was alone present.

Injections.—One of 200,000,000 each of bacillus septus and micrococcus catarrhalis.

Result.—*Almost complete recovery in two days without any subacute stage.*

Subsequent history.—Immunity for over six months, several attacks which seemed to be coming on *aborting completely within an hour or two.* An injection of 150,000,000 each of bacillus septus and micrococcus catarrhalis was then given to secure immunity for a further period, but in about a month a very severe attack due to *micrococcus catarrhalis* came on and further vaccine treatment was emphatically declined.

CASE 32.—

Description.—The patient was very subject to colds with sore throat and cough. In this attack cough was quite absent and the bacillus septus was isolated.

Treatment.—Upon the third day an injection of 250,000,000 of bacillus septus to meet the present attack and 150,000,000 of a stock vaccine of micrococcus catarrhalis to immunise against future attacks from that organism were given.

Result.—Considerable constitutional disturbance for 24 hours, then very rapid convalescence and immunity for six months, when a fresh attack due to the micrococcus catarrhalis supervened. This was met by immediate injection of a small dose of mixed septus, catarrhalis, and Friedlander vaccine which appeared very markedly to shorten the attack. It would thus appear that during nine months only one cold was caught instead of several and this yielded readily to vaccine therapy.

CASE 38.—

Description.—The patient had been very prone to colds which began with cough and sore throat. In *the present* attack sore throat was a prominent symptom but cough was absent. The bacillus septus was isolated.

Treatment.—An injection of 250,000,000 each of bacillus septus and micrococcus catarrhalis and bacillus of Friedlander.

Result.—Complete immunity for four months, then an incipient cold came on and the patient at once *returned for* an injection of 125,000,000 each of bacillus septus, micrococcus catarrhalis, and bacillus of Friedländer. For 24 hours there was some little constitutional disturbance but the cold was completely aborted. Thus during seven months practically complete immunity has been secured and the patient assures me that but for the injections he would certainly have had several attacks in this time.

(*b*) *Colds due to the bacillus of Friedländer.*

CASE 19.—

Description.—The patient was very subject to attacks like the present, *sore throat* and cough being absent. The nasal discharge was very profuse indeed, the subacute stage very pronounced. The bacillus of Friedlander was isolated.

Treatment.—Injection upon the twelfth day of 300,000,000 of bacillus of Friedlander.

Result.—Disappearance of organisms after 32 hours; convalescence complete after five days. Complete immunity for a year.

3. *Case due to Mixed Infection by Bacillus of Friedländer and Micrococcus Catarrhalis.*

CASE 29.—

Description.—The present attack was the fourth within six months. There was very profuse discharge, no sore throat, but bad cough. The bacillus of Friedländer and micrococcus catarrhalis were both isolated.

Treatment.—Upon the fourth day 250,000,000 of the bacillus of Friedlander were given but no micrococcus catarrhalis, none being available.

Result.—Severe constitutional disturbance for 24 hours, then very rapid improvement. The cough, however, persisted for two months; six months later an injection of 250,000,000 of each of the three organisms was given with the result that *complete immunity from* colds has been secured for a whole year.

4. *Case due to the Micrococcus Catarrhalis.*

CASE 41.—

Description.—Attack characterised by bad cough and absence of sore throat. Rhonchi to be heard all over the chest. Micrococcus catarrhalis isolated.

Treatment.—Injection of 250.000,000 micrococci upon the third day.

Result.—Next day the cold itself was much better, *but the cough* persisted to a slight extent for a fortnight. Up to date (four months) there has been no fresh attack.

CASE 37.—Has just commenced treatment, convalescence from an acute attack having already begun; no definite conclusion could be drawn from the one injection, but an attempt is to be made to secure immunity from future attacks.

Conclusions Drawn from the Results of Vaccine Therapy in the above Cases, and Rules for its Employment.

A. Acute colds.—It would appear that by the injection of an appropriate dose of the corresponding bacterial vaccine convalescence in acute attacks of cold can be markedly hastened and complications obviated. My procedure during the last few months, especially in several cases not recorded in this paper, has been slightly altered. The attempt used to be made, not only to deal with the present attack but also to secure immunity at the same time against the other organisms as well. The result of this was, *as mixed stock* vaccines were *usually* employed containing equal numbers of the several organisms, that a dose which was appropriate in an acute attack due to one given organism would contain insufficient numbers of the other organisms to secure future immunity against them. For instance, in a "catarrhalis" cold, a dose of 125,000,000 of micrococcus catarrhalis would be given; this sufficed for that infection, but the dose of 125,000,000 of bacillus septus simultaneously given would not suffice to secure immunity, say, for more than three months *against* this latter organism. Accordingly now the present infection is alone *dealt* with *at first*, and *an attempt* made three weeks later to secure complete immunity by the administration of a dose of 250,000,000 of each of the "cold" organisms.

The best times for dealing with an acute attack are either immediately at the onset or upon the third day. At the former period the cold may be completely aborted; at the latter the onset of the subacute stage may be obviated and convalescence be complete within from *24 to 36 hours.* Inoculation during the interval between the first and third day is not free from risk of *causing considerable* constitutional disturbance. The appropriate doses to employ are 250,000,000 *of* bacillus septus and 125,000,000 of either the micrococcus catarrhalis or bacillus of Friedländer. Should the accurate diagnosis of the infecting organism or organisms not be possible a dose of 75–125,000,000 of the combined vaccine of the several "cold" organisms may be given with safety. I have not, as a rule, found repetition *of the dose* necessary, but should this be so then 500,000,000 of the bacillus septus or *micrococcus catarrhalis* may be given at the end of a week and 250,000,000 of the bacillus of *Friedländer* at the end of a fortnight.

To secure immunity against future attacks the administration of a dose of 250,000,000 of each of the several organisms every four to six months will probably suffice, the first *being* given three weeks after recovery from the acute attack. Should this dosage produce *any marked constitutional* disturbance then a diminished one must be employed upon subsequent occasions.

The Horace Dobell Lecture

ON THE

LATENT PERSISTENCE AND THE REACTIVATION OF PATHOGENIC BACTERIA IN THE BODY.

Delivered before the Royal College of Physicians of London on Nov. 12th, 1908,

BY LEONARD S. DUDGEON, F.R.C.P. LOND.,

BACTERIOLOGIST TO, AND JOINT LECTURER ON GENERAL PATHOLOGY AND LECTURER ON SPECIAL PATHOLOGY IN THE MEDICAL SCHOOL OF, ST. THOMAS'S HOSPITAL.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—My first duty is to thank you for the great honour which you have conferred upon me in asking me to deliver the third Horace Dobell lecture. This honour is still further increased by the fact that the two previous lecturers, Dr. E. Klein and Dr. F. W. Andrewes, have added by numerous investigations so considerably to the advancement of the science of bacteriology.

This lectureship was founded by Dr. Horace Dobell for the purpose of encouraging research in "the ultimate origin, evolution, and the life-history of bacilli and other pathogenic micro-organisms." I have endeavoured as far as possible to discuss certain details concerning the life-history of many of the more important pathogenic bacteria, more especially in reference to their existence in normal tissues and their persistence in the body subsequently to some infective lesion.

It is now being recognised that pathogenic bacteria may persist in the tissues for varying periods without causing any ill-health in the patient in whose tissues they occur, but at any period they may leave their host to infect others or may for some unknown reason excite inflammatory changes in the tissues in which they have been living in an inactive state.

ON THE BACTERIOLOGY OF NORMAL ORGANS.

Ford,[1] in 1901, published the results of researches in the *Journal of Hygiene* on the bacteriological investigations of the normal organs of rabbits, guinea-pigs, dogs, and cats. He found that each species of animals showed its peculiar bacteriology regardless of the condition under which the animals were killed, or the method by which cultures of the organs were made. Thus the staphylococcus albus, staphylococcus aureus, bacillus mesentericus, bacillus proteus, and certain pathogenic spore-bearing bacilli were found in the organs of rabbits and guinea-pigs. Positive cultures of bacteria were grown in a large proportion of cases usually on the sixth, seventh, or eighth day, but in some instances as late as the seventeenth. In summarising the results of these investigations he says: "In whatever manner these latter questions be answered, I must maintain as a result of the experiments here cited that at least 70 per cent. of the internal organs of our ordinary domesticated animals contain bacteria which are capable of development, provided a sufficient time be allowed to elapse between the removal of the organs and the final examination."

Various observers had investigated this subject previously to Ford and had obtained most conflicting results. Some had found the internal viscera invariably sterile; others, such as Zweifel, concluded that anaerobic organisms were habitually present. In a paper published in THE LANCET in 1904, Morgan,[2] from a series of careful bacteriological investigations on the viscera of healthy animals, came to the conclusion that normal organs did not contain pathogenic bacteria and that the presence of non-pathogenic organisms in the cultures is probably due to accidental contamination.

The tissues of the fœtus and of the newly born infant are usually considered to be free from micro-organisms. In children and adults bacteria are found in various parts of the human body. From these facts it is evident that organisms must enter the various tissues soon after birth and persist throughout life. It is these organisms which are the cause of so many of the acute and chronic infections to which we are liable; in fact, auto-infection is universally regarded to be a common source of infection in man.

Professor Welch many years ago drew attention to the presence of the staphylococcus epidermidis albus as a normal inhabitant of the human skin. This staphylococcus we now know to be closely allied to other staphylococci met with in infective processes in man, although Andrewes and Gordon[3] consider it to be a species perfectly distinct from the staphylococcus pyogenes group (albus, aureus, and citreus) and readily distinguishable by its biological characters. We know that these staphylococci are found in the skin after it has been rendered as clean as modern surgical methods permit, that they are of frequent occurrence in the healing of wounds, while, on the other hand, these organisms owing to their persistence in the tissues, are liable to give rise to infections of more or less severity.

Schenk and Lichtenstern,[4] in a paper published in 1901, refer to the bacteriological examination of 43 abdominal wounds. These observers included in the wounds threads of sterilised silk which they withdrew at various intervals and tested bacteriologically. They also examined pieces of skin removed at the commencement of the operation and pieces of fat removed at its termination. Their surgical technique included the use of alcohol and corrosive sublimate in the preparation both of the patient's skin and of the surgeon's hands. Of their 43 cases, 39 healed by first intention, and four suppurated slightly, but only seven cases, or 16 per cent., were found to be sterile, the staphylococcus albus being the predominant organism.

Mr. Sargent and I[5] carried out similar observations on the skin, tissues, and ligatures in connexion with aseptic wounds in the wards of St. Thomas's Hospital. Here antiseptics are not included in the surgical technique, and thus bacteriological investigation can be completed under the most favourable conditions. In these observations of 45 cases treated without chemicals the wound surface was sterile on only 26 occasions and in 15 instances the staphylococcus albus was cultivated. The skin cut from the edge of the wound at the conclusion of the operation was found to be sterile six times in the first 45 cases, while on 30 occasions the staphylococcus albus was found to be present. The suture, removed at intervals varying from 24 hours to six days after operation, was found to give a growth of the staphylococcus albus on 30 occasions out of a series of 45. The exudate at the time of the removal of the suture gave a growth of the staphylococcus albus on 18 occasions. There was only one case of suppuration in the whole of this series. We thus see that organisms belonging to the staphylococcic group are of frequent occurrence in wounds which heal without suppuration; their presence, however, but for bacteriological investigations would be unknown. It is more than probable that the existence of these organisms in normal tissues is an important source of suppurative inflammation in the healing of wounds.

It has also been shown that the staphylococcus albus is one of the most important organisms in peritoneal infections. It has been found to be frequently present in the blood clot in intraperitoneal hæmorrhage and also in the peritoneal cavity in various acute infections. It can be cultivated from the great omentum of normal animals and from the human omentum in cases in which the peritoneal cavity is apparently healthy.

A staphylococcus has been shown to be of frequent occurrence in malignant growths. This organism has been described as the micrococcus neoformans, and this name would suggest that it is an organism possessed of special specific properties. But Andrewes and Gordon[6] consider this micrococcus—at least, the culture which they investigated—to be the staphylococcus epidermidis albus, and Dunkley and I[7] about the same period referred to its identity with the staphylococcus albus. These observations are important

44 per cent. of the patients passing albumin after operation passed acetone. 25 per cent. of these had secondary vomiting. Acetone was present without any secondary vomiting in 16 cases, or 21 per cent. Secondary vomiting without acetone occurred in 3 cases. There were 13 septic cases; of these 9 passed acetone after operation and 5 passed acetone both before and after operation. Of the 7 malignant cases, 3 passed acetone after operation and none passed acetone before operation. The primary vomiting in this series was so marked, consisting chiefly of retching, commencing immediately after the cessation of the anæsthetic, that the series was stopped earlier than was anticipated. The urines in this series were all alkaline before operation and with two exceptions were acid after operation—the two exceptions, we think, were due to decomposition of the urines.

Third series.—These patients were treated with half an ounce of glucose every four hours before operation for six doses, the last dose being given four hours before operation.

	No. of cases.	Per cent.
Total number of cases	100	—
Cases showing acetone in urine—		
Before operation	3	—
After operation	22	—
Cases of primary vomiting	53	—
Cases of secondary vomiting	21	—
Acetone was present in	6	28·0
Marked vomiting	2	—
Acetone was present in	2	100·0

(These cases lasted 28 hours and 24 hours respectively.)

19 per cent. of the patients with albumin in their urine passed acetone. Secondary vomiting occurred in 2 cases, or 40 per cent. These two cases were the only cases of marked vomiting in the series. Cases passing acetone without vomiting numbered 8. There were 12 septic cases; of these, 6 passed acetone after operation and 1 before and after operation. There were 14 malignant cases; of these, 2 passed acetone after operation and 1 before and after operation. The large proportion of primary vomitings in this series led us to suppose the amount of glucose given to be at fault; the dose has been decreased to one teaspoonful. The results appear so far to be more satisfactory. We hope to confirm this by a later series. The glucose is taken much better by the patients than the sodium bicarbonate; it must be given pure or freshly mixed, as otherwise it tastes musty owing to rapid bacterial invasion. In no case was glucose present in the urine either before or after operation. During the whole of the three series increased acidity of the urine after operation was noticed.

Comparative Analysis.

—	Series 1.	Series 2.	Series 3.
Acetone in urine before operation	25·2%	25·4%	3%
,, ,, after operation	60·4%	53·4%	22%
Cases of primary vomiting	54·3%	67%	53%
,, ,, secondary vomiting	30%	34·2%	21%
Acetone in cases of secondary vomiting	89%	88%	28%
Marked vomiting	13·4%	12%	2%
Acetone in cases of marked vomiting	89%	88%	100%
Percentage of patients with albuminous urine passing acetone	42	44	19
Cases of secondary vomiting in (8)	15·8%	25%	40%
Cases of secondary vomiting without acetone	10 cases.	3 cases.	14%
Cases where acetone was present without symptoms	30%	21%.	8%

The anæsthetics given during these three series were with few exceptions either chloroform or C.E. mixture given on a Skinner's mask, or $CHCl_3$ by Junker's inhaler; 32 per cent. were induced by ethyl chloride. The percentage of acetone after the various anæsthetics showed very little change. We could not determine that the time in hospital previous to operation had any bearing on the subject. The average duration of stay was four days previous to operation.

The following previous observations were noted and confirmed: (1) the greater liability of children to symptoms; (2) the frequency in which septic cases, especially abdominal, showed symptoms of acidosis; and (3) the length of anæsthesia was not a great factor in the production of acetone.

The following three cases show the value of sodium bicarbonate in the after-treatment. (For permission to publish Case 1 we are indebted to Dr. H. M. Evans of Lowestoft.)

CASE 1.—The patient, a male, aged 12 years, was admitted for appendix abscess on April 25th last. Vomiting had been present for three days prior to operation. Operation was performed on the 26th at 12 noon. The anæsthetic was A.C.E. and ether by open method. The abscess was evacuated and the appendix was removed. The duration of the operation was 60 minutes. At 2.30 P.M. the patient was extremely restless; the mucous membranes were cyanosed, respiration was irregular, and the pulse was almost imperceptible. There was vomiting of mucus streaked with dark grumous matter. A specimen of the urine passed at this stage showed the presence of albumin and an intense acetone reaction. 10 ounces of sodium bicarbonate solution (grs. v. to ℥ i.) were injected into the subcutaneous tissues of the left axilla. At 4.30 P.M. restlessness and vomiting were still marked; the stomach was washed out with sodium bicarbonate solution (ʒi—O i) and 10 ounces of sodium bicarbonate solution were injected into the right axilla. At 9.30 P.M. the patient was much quieter, the vomiting ceased, and the respirations were regular. On April 26th he was again restless and was vomiting, but not dark matter. The stomach was again washed out with sodium bicarbonate solution. The urine was alkaline; albumin was present and acetone was absent. The further progress of the case was uneventful.

CASE 2.—The patient, a male, aged seven years, was admitted for talipes equino-varus on March 29th last. The operation consisted of excision of the astragalus. The anæsthetic was ethyl chloride and chloroform. The duration of the operation was 60 minutes. The patient became collapsed, and vomiting started in the first 12 hours and continued into the next 24. The grumous matter was again present. The urine showed acetone after the operation. The treatment was confined to the administration of sodium bicarbonate by the mouth—ʒi every four hours. The drug was given 12 hours after operation and the vomiting was quickly controlled. The acetone did not disappear until two days after operation.

CASE 3.—The patient, a female, aged five years, was admitted for congenital ptosis on April 21st last. A plastic operation was performed, the anæsthetic being ethyl chloride and chloroform. Vomiting started in the first 12 hours but became much more marked in the next 24. The child was collapsed. Acetone was present in the urine before and after operation. Sodium bicarbonate had been given before operation and was again given for two days afterwards. The vomiting soon ceased. Acetone was present in the urine until two days after operation.

Prophylaxis.—In the emergency cases, in which we find acetone present before operation, the evidence tends to show that vomiting is more marked after operation; this is especially so in children. Therefore in such cases either of the following methods should be adopted:—1. If possible delay for a few hours to admit of treatment by the mouth or the rectum. The drug may be given in large doses. 2. Surgical procedure, such as transfusion with a sterile 5 per cent. isotonic glucose solution. We would here point out the danger of using such a solution for flushing out the abdomen, owing to the excellent pabulum afforded to bacteria.

Routine treatment.—For children, tablets of glucose grs. 10 four-hourly for 12 doses; for adults ʒi. of glucose four-hourly for 12 doses. This method enables the liver to store up glycogen and so deal with the acid products arising from the toxic action of the anæsthetic. In the after-treatment sodium bicarbonate is still the best drug to use.

During our third series we never had a case which needed any treatment afterwards, so we were unable to judge of the value of glucose given later. After the condition of acidosis has been established, the theoretical combination of the acid with the basic radicle seems obviously correct, but the bases might well be made to include magnesium and calcium as well as sodium. The treatment afterwards therefore resolves itself into giving saline solution either by the tissues or veins to make up for fluid lost by vomiting; to wash the stomach out with a solution of sodium bicarbonate and to leave in

B. Observations on the virulence of diphtheria bacilli persisting for long periods in the throats of infected persons.—There are certain experimental records which show that a general decrease in virulence of the diphtheria bacillus does occur by prolonged stay in the throats of infected persons, but on the other hand there is conclusive evidence forthcoming to prove that these bacilli may persist in the throat and nose for very long periods without showing any decrease in virulence. Dr. Graham-Smith refers to several authors to illustrate these points. Dowson, for example, observed fully virulent diphtheria bacilli in the noses of two children for a period of five months. Schäfer discovered virulent bacilli in the throat of a boy seven and a half months after an attack of tonsillitis. Sevestre and Méry observed two cases in which virulent organisms were present 49 and 38 days after separation of the diphtheritic membrane. Williams reported a case in which virulent bacilli persisted for 157 days. Professor R. T. Hewlett isolated from a boy's throat 22 weeks after an attack of diphtheria bacilli which in small doses killed guinea-pigs in 36 hours. Müller in 1897 observed fully virulent diphtheria bacilli in the mouth of a "contact" for two and a half months. Cobbett in 1901 isolated and examined for virulence the bacilli from the throat of a number of persons on several occasions until the disappearance of the organisms. Bacilli were isolated and found virulent in one case up to the thirtieth day, in another on the sixty-sixth day, and in two "contacts" the bacilli were found to be virulent in one up to the fifty-eighth day and in the other the eighty-second day. In 1901 Prip examined, cultivated, and tested the pathogenicity of the diphtheria bacilli from the time of the disappearance of the membrane in eight cases up to the period when the organisms could no longer be isolated. In one instance fully virulent bacilli were found 335 days from the commencement

These observations which have been referred to conclusively prove that diphtheria bacilli are capable of retaining their virulence for prolonged periods in the throats of infected persons. In a few instances they appear to have lost their virulence to some extent, but in the great majority of cases full virulence was noted up to the time of their final disappearance.

These records given by Dr. Graham-Smith are of great importance because they prove that diphtheria bacilli may persist in the tissues of apparently healthy people without giving rise to any abnormal condition of the throat, but yet in most instances retain their virulence.

Bacillus Proteus.

This group of bacteria is found most commonly in the urine and intestinal tract. In the former it may be the cause of bacilluria and may have been present for varying periods unknown to the patient. It may at any time and for some unknown reason give rise to acute infection of the urinary tract, but this is not, however, of very common occurrence. It is this group of organisms which persists in the urine for indefinite periods and gives rise to attacks of so-called alkaline cystitis. In one instance the organism was present in the urine without producing any symptoms—in fact, the abnormal condition of the urine was disregarded—but after removal of the uterus for fibromyomata the abdominal wound became infected with this organism and gave rise to a chronic gangrenous condition of the surrounding tissues which it is especially liable to do. It is known that in some cases of cerebral abscess the only organism which is cultivated from the pus may be one of the proteus group. This fact is of great interest because in some cases of chronic middle-ear disease the discharge will be found to show the presence of this bacillus in pure culture. The proteus group serves as an excellent illustration of the all-important fact referred to elsewhere in this lecture—namely, the persistence of an organism in the tissues for indefinite periods without giving rise to any symptoms, but occasionally acting as the cause of some acute illness.

Bacillus Coli.

This organism, as we know, is a normal inhabitant of the intestinal tract in man and animals. It may persist here without giving rise to any acute or chronic infection of which the patient is conscious. On the other hand, it is the most constant organism met with in the bacteriology of peritonitis,[12] especially in the commonest variety, that due to appendicitis. It persists in the appendix after the acute stage has subsided, and may after removal at the quiescent period give rise to acute diffuse peritonitis. It is owing to the active part this bacillus is known to play in peritonitis which has led to the practice by some surgeons of having cases of the kind vaccinated with this organism a few days previous to operation.

Perhaps the most interesting condition with which we are acquainted is infection of the urinary tract caused by this organism. We know that it is frequently met with without giving rise to any inflammatory condition and without any symptoms, but for some unknown reason it may produce various acute infections not sufficiently recognised even at the present day. I have notes of a case in which the bacillus coli was present in the urine although the patient and her medical adviser were unaware of any abnormal condition of the urine. At the sixth month of pregnancy she was taken ill with an acute disease associated with high temperature and rigors proved to be due to the bacillus coli which previously had been multiplying in the urine without exhibiting any evidence of pathogenicity. In other instances, although it may be present in such enormous numbers in the urine as to give rise to the term bacilluria, it may not occasion even a slight degree of pyrexia. In other cases the first indication of any acute illness may be an acute febrile disease clinically indistinguishable from typhoid fever and which can only be diagnosed by bacteriological methods. In those cases which I have met with of this character the presence of the bacillus coli was proved previously to the acute illness—that is, at a period when the patient was in apparently good health. Further, this organism which normally exists in our tissues appears to play a part sometimes of great importance in typhoid fever. It is known that in this disease it is frequently met with in the urine, giving rise to bacilluria and certain other conditions.

It is important to recognise that these organisms as a rule retain their pathogenicity for the lower animals quite apart from the source from which they have been isolated in man.

Bacillus Typhosus.

Most people are agreed at the present day that by the term "typhoid fever" we understand certain clinical phenomena which are due to infection with various micro-organisms belonging to the typhoid-coli group and not necessarily to the specific micro-organism, the typhoid bacillus. This fact serves to explain why acute diseases regarded as typhoid fever on their clinical manifestations have failed to give a positive typhoid agglutination reaction at any period of the disease, quite apart from those rare instances of true infection by means of the bacillus typhosus which also fail to give this reaction. Such an instance occurred in the case of a well-known medical man who directly infected himself with the typhoid bacillus and whose blood up to the time of his death failed to give a positive reaction. Still further, it is now recognised that we may have infection with the typhoid bacillus without any of the clinical manifestations of typhoid fever.

These facts have been specially emphasised in a most valuable paper recently contributed to the *Journal of the Royal Army Medical Corps* by Major J. C. B. Statham.[13] He says: "Before we can profitably discuss the question of typhoid or enteric etiology, it is necessary to clearly realise what these words mean both in their clinical and bacteriological senses. Typhoid means typhus-like and was used to represent the clinical picture of prolonged fever—abdominal symptoms, exhaustion, and mental apathy—often present in this disease. The word 'enteric' was introduced owing to the prevailing idea that intestinal lesions and certain symptoms were always present in typhoid Now these terms 'typhoid' and 'enteric' have the sanction of long usage and will stay in consequence, but unless we are careful this nomenclature is liable to lead us into diagnostic error and has possibly even helped to keep alive and spread endemic and epidemic typhoid." "15, even 10 years ago, it might have been confidently stated that in the bacillus typhosus of Eberth had been found the unique causal agent of the dangerous and widespread disease 'typhoid fever.' The knowledge of recent years has forced us to realise that there are quite a number of allied but distinct of tearing through the pia mater the blood was extravasated between that membrane and the brain substance; it tracked round the optic chiasma and pons to the side of the medulla and thence poured by way of the iter into the ventricles.

[13] Major J. C. B. Statham: The Complex Nature of Typhoid Etiology and the Rôle Played by Animals and Man in the Spread of the Typhoid Group of Diseases. Journal of the Royal Army Medical Corps, October, 1908, No. 4, vol. ii.

The diagnosis of ruptured cerebral aneurysm was based on the sudden onset with vomiting and occipital headache, together with the remission of the symptoms. The blindness of the right eye appeared to be a disturbing factor in the diagnosis; it was, presumably, explained post mortem by the pressure of the aneurysm on the right optic nerve. A specimen is preserved in the University College Museum in which the same condition is present. The alternative diagnosis was that of syphilitic meningitis and the improvement in the patient's general state, concurrent with antispecific treatment, lent for a time support to that belief. It is probable that the symptoms at the onset were due to a small rupture of the aneurysm; this furnishes an explanation for the brown staining observed in the neighbourhood of the optic nerves. The aperture was plugged by blood clot and the effused blood was gradually absorbed with temporary relief to the patient's condition; then, on the sixteenth day, the second rupture took place (perhaps due to straining at stool) and death resulted. Although a history was not obtained the etiology of the aneurysm was presumably syphilitic. This is the most plausible explanation for the atheromatous and degenerative state of the arterial vessels in so comparatively young a subject and many of the recorded cases of cerebral aneurysm have a syphilitic origin.

The case is of interest owing to the rare condition and the period of 16 days that elapsed between the primary rupture of the aneurysm and the fatal issue. With regard to the first point, the anterior cerebral artery holds the fourth place in the order of frequency of aneurysms of the cerebral vessels, the middle cerebral, the basilar and the internal carotid being more commonly affected. Beadles,[1] after an exhaustive review of 555 cases of cerebral aneurysm, states that "in aneurysms of the anterior cerebral and anterior communicating arteries the number in which definite cerebral symptoms occurred is so trifling and so vague that most certainly such an aneurysm is impossible of diagnosis." In this case, however, definite signs, the expression of a grave cerebral lesion, were present. The first symptom of the aneurysm was its partial rupture. This, of course, obtains in many of the cases recorded in the literature, the other types being (*a*) those in which no symptoms existed during life and the patient succumbed to some intercurrent disease; and (*b*) those cases where the apoplectiform seizure was preceded by pressure symptoms and signs simulating those given by a cerebral tumour.

As a rule, rupture of the aneurysm is followed by speedy death, and if the terminal event is delayed the interval between the primary and secondary rupture of the aneurysm is not of the duration noted here. In van der Byl's[2] case of rupture of the posterior cerebral the patient was taken to Middlesex Hospital, having fallen down in the street in a fit and having died while in the waiting room. Dr. J. Rose Bradford[3] records a case of aneurysm of the basilar artery in which the patient lived for 40 hours from the onset of his symptoms, and he draws attention to the long survival between the first and second rupture. Optic neuritis and absent knee-jerks are no new features in the physical signs that a cerebral aneurysm may present.

In conclusion, I must express my thanks to Dr. Rose Bradford for his kindness in permitting me to publish the case.

Brompton, S.W.

THE RESEARCH DEFENCE SOCIETY.—A public meeting in connexion with the Research Defence Society will be held in St. William's College, York, on Friday, Dec. 11th, at 3.30 P.M., when a lecture will be given by Mr. Stephen Paget on the work which has been done. The following amongst others have signified their intention of being present:—Lord Deramore, the Dean of York, Canon Watson, Canon Robinson, Rev. C. C. Bell, Mr. W. H. Jalland, Dr. F. Shann, Dr. R. Turner, Dr. Macdonald, Mr. E. R. Dodsworth, and Mr. H. V. Scott. The honorary secretary of the York branch is Mr. Gerald S. Hughes.

A NOTE ON THE BACTERIAL CONTAMINATION OF MILK AS ILLUSTRATING THE CONNEXION BETWEEN FLIES AND EPIDEMIC DIARRHŒA.

BY J. T. C. NASH, M.D. EDIN., D.P.H. CANTAB.,
COUNTY MEDICAL OFFICER OF HEALTH OF NORFOLK.

MY views on this subject are well known and on some future occasion I shall revert to the whole matter. The object of the present communication is to record briefly the results of two simple experiments which I made in the summer of 1907.

I. The first was undertaken on a warm day in August, 1907, as follows. Two well-cleansed saucers were three-fourths filled with milk from the ordinary household supply. [This supply is subject to rather stringent conditions under guarantee.] One saucer was then covered over with a clean plate, the other was left exposed, both being placed on the same table in the kitchen. Some flies were observed in the room. Apart from the circumstance that one saucer was covered and the other uncovered, both were under identical conditions as to temperature, &c. Five hours later the uncovered milk was found to contain the bodies of two flies, and I proceeded to subject both milks to bacteriological tests, the results of which may be summarised as follows (both samples being kept covered, after the removal of the two flies which were in the sample which had been exposed for five hours):—

Sample.	Number of bacteria per c.c. (as estimated from gelatin [illegible] at 22° C. Dilution = 0·0001 c.c. original milk).	Taurocholate broth [illegible] c.c. after 18 hours.	Glucose bile salt litmus broth 0·001 c.c. original milk.		Anaerobic milk culture for spores.
			Acid.	Gas.	
A (uncovered) containing two flies.	7,425,000 (after five hours' exposure).	Uniform turbidity.	+	+ ¾	–
B (covered over).	3,100,000 (after five hours covered over).	,,	+	+ ¼	–

These results indicate that in five hours on a warm day milk exposed to flies contained millions more of gas-forming bacteria than the same milk kept covered over.

The following observations are significant of the *physical* deterioration of the exposed fly-containing milk as compared with the protected milk (both samples being kept covered, after the removal of the two flies which were in the sample which had been exposed for five hours):—

Sample.	August 15th, after 24 hours.	August 16th, after 48 hours.	August 17th, after 72 hours.
A	Slight putrefactive odour.	Stinking odour more marked; milk clotted.	Odour still more marked; milk acid.
B	*No odour.*	Milk clotted; ordinary smell of sour milk.	No putrefactive odour; only that of lactic acid fermentation.

II. The second experiment was made in September, 1907. The temperature was 72° F. in the laboratory. Two portions of the same sample of milk hereafter referred to as C and D were placed in the same room in a cottage in which flies were present. Sample C stood exposed from 4 P.M. on the 11th until 8 A.M. on the 12th. Sample D was covered over but otherwise subject to exactly *similar* conditions. Both samples were subjected to bacteriological tests at 4 P.M. on the 12th. [With regard to the physical condition, the exposed milk– Sample C—contained two flies floating in it. It was observed that the *ovipositors* of these flies were completely extruded in each fly. The milk had a slight putrefactive odour and already there was a tendency to clot.

and a gall-stone was present in the gall-bladder. Typhoid bacilli were isolated from the liver, spleen, bile, and interior of the gall-stone. Levy and Kayser consider that this case is an example of auto-infection—the bacillus persisting in the patient's gall-bladder, similarly to the numerous examples concerning other bacteria quoted throughout this lecture. It was practically living as a saprophyte until finally it gave rise to the fatal infection. There seems to be considerable evidence in favour of auto-infective attacks caused by the bacillus typhosus.

Cases of exceptional interest have recently been investigated by Huggenburger,[20] assistant at the Bacteriological Institute in Zürich. 13 cases of enteric fever had occurred in one family. In 1877 the mother had typhoid fever, in 1886 the father, in 1892 the son, in 1902 the daughter-in-law, and nine servants from 1899 to 1908. A bacteriological examination was made of the excreta of all members of the household. Virulent typhoid bacilli were isolated from the fæces of the mother who had had no symptoms since her illness in 1877. These cases, therefore, stretch over a period of 30 years. Although this organism had been present in her tissues for this considerable length of time, it had never given rise to any symptoms, but is regarded as the source of infection in the other members of the household.

In the Army Medical Report for 1907 some interesting investigations were made of 11 cases of typhoid fever occurring at Kasauli. It was found that the soldiers' cook had the bacillus typhosus in his fæces although he was in perfect health and had not been in hospital for eight years previously.

At the Central Research Laboratories at Kasauli the excreta from typhoid convalescents were repeatedly subjected to bacteriological examination and also those from a large number of healthy men. In three of the latter group typhoid bacilli were isolated, and in each instance these men had been nursing cases of enteric fever. In these laboratories it was pointed out that the excretion of typhoid bacilli in the fæces was markedly intermittent, intervals as long as 80 days occurring.[21]

In July, 1906, Gray and I published a case concerning a man who had the typhoid bacillus persisting in his tissues for four years and which probably gave rise to typhoid fever in a member of his family by direct infection. In July, 1902, he was in the wards of St. Thomas's Hospital for typhoid fever under the care of Dr. Hector W. G. Mackenzie. He was discharged on Sept. 10th, re-admitted on Sept. 18th for pain in the right femur, and left the hospital three weeks later quite well. On Oct. 18th, 1904, more than two years after the attack of typhoid fever, he was readmitted for tenderness over the right femur. On Nov. 6th an abscess was opened and a pure culture of the bacillus typhosus was obtained from the pus. He left the hospital on Dec. 21st, 1904, with the wound healed, but a few weeks later the scar gave way and pus was discharged through a sinus. In June, 1905, the patient came to the hospital for further treatment. In the same month his wife was admitted to St. Thomas's Hospital suffering from a severe attack of typhoid fever which proved fatal. The patient stated that his wife collected the soiled dressings after he dressed the wound and then burnt them. No one else had had typhoid fever in his house so far as he knew. In July, 1905, the pus was re-examined and the bacillus typhosus was isolated. The patient's serum failed to cause homologous agglutination, but a standard human typhoid serum and immune horse serum produced a high degree of agglutination with the patient's bacillus. The fact that the patient's serum fails to agglutinate the homologous bacillus in cases of this class has been noted by Dr. Dean and other observers. On Dec 9th of the same year the bacillus typhosus was still present. In February, 1906, dead bone was removed by Mr. W. H. Battle and the bacillus typhosus was isolated from the depth of the wound. This was then washed out daily with a 1 per cent. solution of urotropin with the result that in a few days the bacillus typhosus could not be cultivated, and at the end of March a similar result was noted. In this case, therefore, we have the persistence of the typhoid bacillus in the tissues for four years without producing any greater effect than local necrosis of bone. If, as is probable, the patient's wife was infected by it, it shows that the organism was still highly virulent when transplanted in the tissues of a fresh host.

In 1908 a man was admitted to St. Thomas's Hospital suffering from cholelithiasis. He had served in the army and in India, but he was never known to have had typhoid fever. In 1900 the patient had a severe attack of colic but no further attack until six months before he came to St. Thomas's Hospital. In January, 1908, he gradually became jaundiced and was admitted to the hospital. The urine contained bile pigment, Cammidge's test was positive, and the fæces were dark in colour. His leucocytes numbered 2280 per cubic millimetre, but the differential count was normal. The serum gave a positive reaction on a standard laboratory culture of the bacillus typhosus with a dilution as high as 1 in 500 within 30 minutes at room temperature. A gall-stone was removed at the operation by Mr. H. H. Clutton from his gall-bladder, but the interior of the stone was found to be sterile. From his bile the bacillus typhosus was isolated in pure culture. The urine was sterile and the fæces on two examinations only failed to show the presence of the typhoid bacillus. Three weeks later the bile was re-examined and the bacillus typhosus was still found to be present. Several re-examinations were made at subsequent intervals but the bacillus typhosus was never isolated again, only the bacillus coli. This patient was treated with a typhoid vaccine which I made from the organism isolated from his bile. He received seven doses in all, commencing about a fortnight from the time of the operation.

In April, 1908, a man was admitted to St. Thomas's Hospital under the care of Mr. G. H. Makins suffering from jaundice. He had had jaundice for six weeks 30 years before, and "influenza" 20 years ago. The jaundice had lasted for one week. There were high pyrexia and rigors. At the operation a suppurative condition of a large thick-walled gall-bladder was found from which the bacillus paratyphosus B. was obtained in pure culture. The patient eventually died and at the post-mortem examination a suppurative cholangitis was found and carcinomatous disease of the gall-bladder. In this case it is impossible to say when the paratyphoid bacillus entered the body. He was never known to have had typhoid fever and the only illness which might have been mistaken for paratyphoid fever was "influenza," which occurred 20 years previously. The importance of finding one of the paratyphoid bacilli in this case is considerable. In the first instance, as already stated, the patient was never known to have had "typhoid fever," but he was admitted to a surgical ward for suppuration in the biliary passages caused by an organism which is usually associated with a febrile illness similar to clinical typhoid fever. The greatest danger likely to arise in a case of this kind is the occurrence of typhoid fever among the patients or nurses, although nothing of this nature developed from this bacillus. The point which is of greatest interest is whether the bacillus persisted in the patient's biliary passages as a saprophyte, became re-activated, and gave rise to suppuration in a carcinomatous growth, or had it only quite recently entered from the intestinal tract?

On March 27th 1908, a man was admitted under the care of Mr. Clutton in the wards of St. Thomas's Hospital who had been jaundiced for five weeks. There was no history of typhoid fever nor of any disease resembling it. At the operation gall-stones were present in the gall-bladder and a condition of suppurative cholecystitis. The interior of the gall-stones was found to be sterile, but from the pus in the gall-bladder a bacillus presenting all the morphological and cultural tests of the typhoid bacillus in every detail was isolated. The patient's serum agglutinated it, but positive typhoid serum produced no effect either when the organism was recently isolated or after it had been cultivated on artificial media for one week at room temperature. The patient's serum also failed to have any agglutinative action on a culture of the bacillus typhosus. In this case an organism was isolated from the tissues which, when subjected to a detailed cultural examination, was found to be indistinguishable from a typhoid bacillus, but yet cannot be classed as such owing to the completely negative results obtained with the serum tests.

During the last two years bacilli of the paratyphoid group have been isolated from three private patients whose urine I have examined. In two cases the organism was accompanied

Figs. A and B will make our meaning clear. In Fig. A the contents of the thoracic cavity are exposed from behind. The left pleural cavity is distended by a pleural effusion, the left lung being compressed towards its root, and the posterior mediastinal mesentery, formed by the approximated leaflets of the right and left pleuræ between the œsophagus and aorta, bulges towards the right so as to compress the base of the right lung. The extension of the posterior mediastinal mesentery is best seen in the transverse section shown in Fig. B, *b*. The heart also is forced towards the right, pressing against the root of the right lung, while the left lobe of the thymus is pushed upwards into the root of the neck. It will be observed that the extension of the left pleural cavity across the line of the spinal column is triangular in shape; its base is below, behind the diaphragm, its apex above at the level of the roots of the lungs. Above the roots of the lungs the line of separation between right and left pleural cavities is normal in position. Were such a chest to be percussed out an area of dulness to the right of the mid-line of the spine and corresponding to Grocco's triangle should be found.

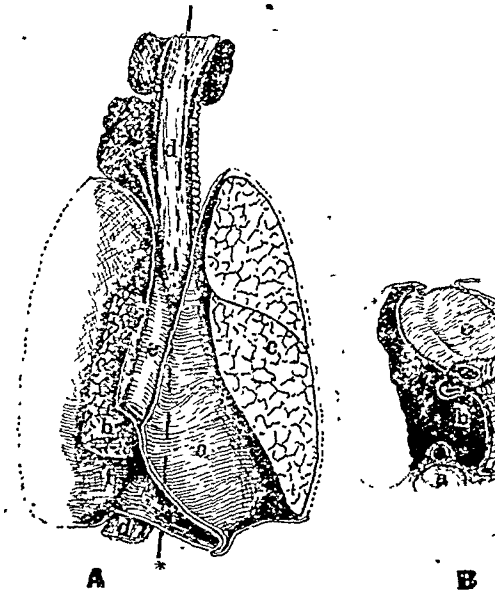

Fig. A. The contents of the thoracic cavity exposed *from* behind. The line of the spinal column is indicated *.... .*. *a*, the posterior mediastinal mesentery bulging into the right pleural cavity; *b*, compressed left lung; *c*, right lung compressed at its base; *d*, œsophagus; *e*, aorta; *ff*, left pleural cavity; *g*, left half of the thymus pushed into neck.
Fig. B. Section of thoracic contents. *a*, on body of vertebra; *b*, left pleural cavity extending to right; *c*, œsophagus and inferior vena cava; *d*, right lung; *e*, right ventricle.

The condition of parts corresponds exactly to the description given by Professor G. Elliot Smith,[1] only that the case examined by him was an adult and the pleural effusion on the right side. He explains the triangular shape of the pleural extension as due to a pendulum-like movement of the contents of the thorax, the collection of fluid in the basal part of the right pleural cavity causing the thoracic contents to swing to the left. All other observers, so far as we know, have dealt with the causation of Grocco's triangle from a clinical and physical point of view. Dr. W. Ewart, who was the first in this country to explain the clinical signs of Grocco's triangle, ascribed it to the pleural effusion acting as a mute and preventing the vertebral column from conducting the pulmonary resonance. Dr. F. W. Forbes-Ross[2] regards Grocco's triangle as a "physical necessity of the anatomical conformation of the posterior chest wall"; Roch and Dufour[3] reach practically the same conclusion. Like Dr. Forbes-Ross they ascribe the triangle of dulness chiefly to the musculature of the back. Dr. Ewart in a later paper[4] notes the fact that a similar triangle is present in case of subphrenic abscess. He believes that the fluid content of such an abscess acts, like a pleural effusion, as a mute on the spinal column. On theoretical grounds we should expect a subphrenic abscess to produce Grocco's triangle, but in a manner different from that supposed by Dr. Ewart. Recently Dr. W. Pasteur[5] has dealt with "massive collapse" of the base of the lung as a sequence of subphrenic abscess and other abdominal inflammatory states; he ascribes, and we think rightly, the pulmonary collapse to a cessation of action and relaxation of the diaphragm on the diseased side, a reflex inhibition following on the subphrenic inflammation. The dome of the diaphragm on the diseased side is found to be raised upwards; there is a considerable diminution of the pleural space on the diseased side, with a corresponding loss of the elastic traction of the basal part of the lung. On the basal part of the sound side there is the usual negative pressure, with the result that the collapsed basal part of the lung on the diseased side is drawn towards the sound side, giving rise to a triangular area of dulness.

Another reason for placing this case on record is again to draw attention to the clinical and physiological importance of the structure named here, the posterior mediastinal mesentery, described and figured by one of us in these pages some five years ago.[6] It corresponds to the translucent triangle seen in the corresponding part of the thorax when the patient is examined in a suitable position by the aid of x rays. This mesentery has been overlooked by anatomists owing to the body being hardened and always examined in the supine position, when the heart and mediastinal contents are pressed backwards against the spine. It can be well demonstrated during the course of a post-mortem examination when the sternum and costal cartilages are removed. If the pericardium with its contents be then lifted forwards the posterior mediastinal mesentery will be seen to stretch from the pericardium to the spine and to have a front to back extent of from one to two inches. In our opinion Professor Elliot Smith is justified in applying the term pendulum-swing to the contents of the thorax; when a full breath is taken the heart and roots of the lungs can be seen to move forwards and downwards following the direction taken by the descending diaphragm. To permit that movement the posterior mediastinal mesentery must be slack and long; it is its slackness and extensibility that permit so free and easy an extension of the contents of one pleural cavity towards the side which has the higher negative pressure; the mesentery being triangular in shape, apex above and base below, retains that outline when pressed into the sound side by a collection of fluid on the diseased side, thus giving rise to a triangle of dulness such as is described by Grocco. We believe that those who have described this condition in sound normal individuals have used a light method of percussion and elicited the triangular dulness yielded by the erector spinæ.

MEDICAL SECTION.

Resistance of Arteries to External Pressure.—An Excitant for Leucocytes of Healthy Persons in the Blood Plasma of Patients Suffering from Carcinoma.

A meeting of this section was held on Nov. 24th, Dr. S. J. Gee, the President, being in the chair.

Dr. W. P. Herringham and Mr. F. Womack, from the Physics Laboratory of St. Bartholomew's Hospital, communicated a paper on the Resistance of Arteries to External Pressure, detailing experiments on the value of the sphygmomanometer as a test of the blood pressure. Small glass tubes were tied into arteries removed from dead bodies and connected with a water-pressure system on which was interpolated a mercury manometer. The artery was placed inside a large glass tube closed at each end by perforated rubber corks through which the small tubes ran. The large outer tube was connected with a reservoir of water, and through this with a column of mercury, by which pressure inside the large tube and outside the artery could be measured. The pressure inside the artery when the system was open was his condition on discharge being that all ulcers had healed and the state of his general health had improved in a marvellous way (he had gained 8 pounds).

[5] The Lancet, Nov. 7th, 1908, p. 1351.
[6] The Lancet, March 7th, 1903, p. 633.

The rapid progress which was made in this case was extraordinary, more especially the way in which the ulcers healed without any local treatment. My reasons for considering this to be probably a specific case was the character of the throat ulceration, age of patient, &c.

CASE 9.—Private ——, Irish Guards, was admitted on August 8th with indurated sore on penis, enlarged inguinal and cervical glands, and maculo-papular eruption scattered over the trunk. He went through the usual course of soamin and was discharged to duty on the 31st, all active signs having disappeared. His general health had much improved (he had gained 5 pounds in weight).

CASE 10.—Private ——, Grenadier Guards, was discharged from the Royal Herbert Hospital, Woolwich, on June 26th, where he had been then under treatment for 30 days for syphilis and had received 25 inunctions of mercury. He was admitted to Rochester Row on August 10th with indurated scar on the penis, mucous patches on the inside of the cheeks and tongue, and ulceration of the throat, and he was covered with a bright roseolar rash. He went through the course of soamin (100 grains) and was discharged from hospital on Sept. 6th. After having had four injections all ulcers in the mouth had healed and on completing the full course his general health had much improved (he had gained 5 pounds in weight). This case was notable from the rapid manner in which the patches and ulcers healed without any local assistance.

CASE 11.—Lance-Corporal ——, A.S.C., was placed on the syphilis register at Woolwich on Feb. 17th, and was stated to have been suffering from a scar on the penis, shotty glands in the groin and neck, and roseolar rash on the body. He had received 19 mercurial inunctions and 12 mercurial injections of one of the soluble salts. He was admitted to Rochester Row on August 11th with condylomata and mucous patches on the penis, scrotum, and tongue. He was put on the course of soamin, which he completed and was discharged on Oct. 1st, all symptoms having disappeared. His health had much improved (he had gained 6 pounds in weight).

CASE 12.—Private ——, Cameron Highlanders, was admitted on August 17th with typical Hunterian chancre on the penis, inguinal and cervical glands, shotty ulceration of the throat, and roseolar rash on the body and the limbs. He completed a course of soamin and was discharged on Sept. 14th. The sore had quite healed, the induration had disappeared, as had also the rash and the other symptoms, and the general health was much improved.

CASE 13.—Private ——, Irish Guards, was admitted on August 27th. This was a neglected case. There was a sore under the prepuce and phimosis was present, necessitating circumcision, as well as a well-marked papular eruption over the trunk, the legs, and the arms. The deep inguinal and cervical glands were enlarged, and there was ulceration of the throat. A full course of soamin was completed, and when the patient was discharged from hospital all active symptoms had disappeared and his general health was excellent.

CASE 14.—Private ——, Scots Guards, was transferred to Rochester Row from another hospital where he was reported to have been doing badly. His condition on admission was generally bad; he was much debilitated and run down. The deep inguinal and cervical glands were enlarged and shotty; the inside of the cheeks, the tongue, and the throat were badly ulcerated; and there was a papulo-pustular eruption on the back and the flanks. The patient has completed a full course of soamin and has done remarkably well. All the ulcers healed rapidly and the rash has practically disappeared.

CASE 15.—The patient, aged 55 years, contracted disease 25 years ago when he had all the classical signs of the disease in its primary and secondary stages. He went through various spasmodic courses of specific treatment at various periods but never had a thorough course. For many years he was quite free from any symptoms until five years ago, when his tongue became sore and leucoplakia formed on it; at the same time an ulcer appeared in the middle of the lower lip; both these lesions have resisted all treatment, including mercury and iodide of potassium internally over long periods. The patient came under my notice on August 31st. The tongue was furrowed from old ulceration and was marked with leucoplakia, which was well raised in places; there was an ulcer on the lower lip scabbed over; this had been present for the past five years and had been diagnosed as epithelioma on more than one occasion. There was no enlargement of the lymphatics in the neighbourhood. The patient was put on soamin injections, of which he had a full course. After the sixth injection (60 grains) I noted: "Ulcer on lip looking decidedly healthier, general health much improved." After the tenth injection: "Ulcer almost entirely healed, tongue improved, mucous membrane of mouth in much better condition." Further treatment for the present was stopped. The rapid improvement was certainly a surprise and the way in which this old-standing case responded to the arylarsonates was remarkable. After the eighth injection the patient showed signs of toxic effects—i.e., noises in the head and a slight attack of colic; these passed off and he completed his course—in fact, he had a total of 110 grains.

CASE 16.—The patient, aged 54 years, contracted syphilis 30 years ago, when he went through three courses of treatment at Aix-la-Chapelle in two years. There was no further return of the disease until two years ago, when after a severe attack of influenza his tongue became very sore and eventually it ulcerated, leucoplakia also appearing on it. At first the condition was diagnosed as cancer, but eventually syphilis was substituted for the latter and he was treated accordingly. I saw him first on August 25th. The tongue was much thickened and ulcerated both on the dorsum and at the sides, and it was covered with leucoplakia; the inside of the cheeks also was thickened and ulcerated. The gums were in a dreadful state of ulceration the result of excess of mercury. The patient had actually been taking a mixture containing solution of perchloride of mercury and iodide of potassium three times a day for eight months continuously before coming to me. He complained of cramps, especially at night time, in the calves of both legs, and also "pins and needles" in the feet and the toes. Ankle clonus was normal. The patellar reflex was diminished in the right leg and normal in the left. The pupils were normal, the general health much below par, and there was loss of sleep and of appetite. The patient went through a full course of soamin (100 grains), at the end of which the tongue and the mucous membrane of the mouth had much improved, whilst the general health had remarkably done so. Appetite and sleep returned. After the eighth injection the patient complained of noises in the head and a peculiar feeling in both legs.

Notes on Cases Treated with Arsacetin.

CASE 17.—Private —— was admitted to hospital on Sept. 25th. On admission he had two small, hard, roundish lumps under the skin of the prepuce; there was no ulceration, and he said that the skin had never been broken, but that was doubtful. He stated that he had had the lumps for the last six months and that he noticed a rash upon him three days before admission. The rash was roseolar in type and was most marked on the chest and the abdomen. The inguinal glands were not enlarged, but those in the neck were hard and shotty. The throat was a little congested. The patient's weight on admission was 12 stones 7 pounds. Oct. 7th: The patient had had four injections of arsacetin (28 grains). The rash was fading and in some places had quite disappeared. The throat was much better and the two small indurated lumps in the prepuce were softer. The patient's weight was 12 stones 12 pounds—a gain of 5 pounds. Oct. 14th: The rash had quite disappeared, the throat was better. Weight 12 stones 13 pounds. Oct. 21st: The patient had had 70 grains of arsacetin. All active symptoms had disappeared and he was apparently in excellent health and was accordingly discharged to duty.

CASE 18.—Private ——, Irish Guards. Admitted to hospital on Sept. 30th with a well-marked papular eruption all over the body, the chest, the abdomen, the arms, and the legs. The papules were large and some were lenticular and well raised and a few were scaly. The scalp was more or less covered with a papular, and in some places a pustular, eruption and there were some pustules at the junction of the nose and forehead and some on the lower lip. The patient was in hospital on August 22nd with a small hard suspicious sore on the frænum and he left the hospital on Sept. 1st. The hair was falling out and the patient complained of severe frontal headache at night time.

another microscope were shown on a warm stage some eggs from fresh urine developing embryos, the urine having been kindly supplied by Fleet-Surgeon P. W. Bassett-Smith, R.N., from Haslar Hospital. Dr. Sandwith also showed a series of photographs of the natural history and pathological results of the worm and exhibited a model of Mr. Owen Richards's vesical calculus weighing nearly 32 ounces.[1] As it has so often been stated that stones in the Egyptian bladder are directly caused by a nucleus of bilharzia eggs, for which idea there seems to be little or no foundation, Dr. Sandwith pointed out that in the Egyptian peasant, from whom this stone was removed by piecemeal extraction with osteotome and mallet above the pubes, with free perineal drainage, no bilharzia eggs were found in the urine either before or after the operation. By the side of this stone was shown a model of Mr. H. M. N. Milton's calculus, which alone surpassed it as the largest ever successfully removed from a living patient. Mr. Milton's stone weighed 34½ ounces, and was extracted whole by abdominal section.[2] The original stones both lie in the Museum of the Royal College of Surgeons of England.

Mr. J. **CANTLIE** read a paper on Lesions of the Rectum and Sigmoid Flexure met with in Post-dysenteric and other cases of Intestinal Flux. He said that before describing the pathological states of the rectum and sigmoid flexure it was necessary to draw attention to certain anatomical details which were essential to the better understanding of the lesions of this part of the alimentary canal. From clinical observations gathered during examinations of the rectum by the sigmoidoscope he was induced to examine the rectum and sigmoid flexure anatomically more closely in order to ascertain if an explanation could thereby be afforded of certain frequently occurring conditions, more especially in post-dysenteric diarrhœa. Shortly the results of his anatomical observations were these:—1. That at the junction of the sigmoid flexure and rectum in the normal bowel of the adult a well-marked narrowing took place which had for its basis a ring of thickened circular muscular fibres of the intestine and a blending of the longitudinal muscular bands at the same spot. These conferred upon the narrowing referred to an action similar to the pylorus of the stomach and he had named this the "sigmo-rectal pylorus." The functions of this opening were retentive to the contents of the colon and prevented the fæces accumulating and pressing upon the anus, thereby doing away with the constant feeling of the desire to defæcate which fæces in the rectum always induced. 2. The junction of the colon and sigmoid flexure presented another narrowing with similar anatomical features which he had named the "colo-sigmoid pylorus." This upper opening, less narrow than the lower or sigmo-rectal pylorus, assisted in the retention of the fæces in the colon and served to mould the fæces to the rounded shape which they assumed in normal stools. 3. At the insertion of the levator ani into the rectum about half way up there was a functional narrowing of the rectum caused by the action of the muscle. When this muscle was relaxed they had the ballooning of the rectum but the causes of this relaxation and consequent ballooning in certain conditions of the rectum were not yet known. So that proceeding from below upwards they had: (*a*) the anal sphincters for one and a half inches; (*b*) a tubular portion of the tube with a longitudinally arranged mucous membrane for some two and a half inches; (*c*) the insertion of the levator ani; (*d*) a puckered portion of the rectum with a sacculated mucous membrane for four inches; (*e*) the sigmo-rectal pylorus; (*f*) a dilatation behind this pylorus with a mucous membrane in irregular folds; (*g*) the upper or colo-sigmoid pylorus; and (*h*) the descending colon. The lesions of the lower part of the bowel might be arranged under three headings: 1. Lesions acting on the rectum and sigmoid flexure from without. Short of causing actual obstruction, these caused what might be called passive shedding of mucus seen especially in intestinal casts. A pregnant uterus, a retroverted or retroflexed uterus attended by increased size of the organ, fibroids of the uterus, ovarian tumours, inflammatory adhesions around the left ovary, tumours of the pelvic walls, tumours of the omentum, appendicitis, aneurysm of the left iliac arteries, enlargement of the left kidney whether from cystic disease or hydronephrosis, in fact, any pressure from without might not only be associated with mucus in the fæces but might induce retention and a diarrhœa of retention. It was necessary, therefore, in all cases of persistent mucus in the stools not associated with a previous history of dysentery and with absence of blood in the mucus combined with a fair state of health to examine for abdominal lesions extraneous to the bowel. 2. Lesions might arise in the wall of the bowel. The most common of these were malignant disease or fibrous stricture but it was possible that both of these were secondary to troubles arising within the gut itself. 3. In regard to lesions arising within the bowel it was difficult in the present state of our knowledge to separate 2 from 3 in this enumeration, for although they knew that thread-worms, bilharzia, and factors of this nature induced changes in the intestinal walls it was difficult to state whether the several lesions which determined intestinal flux were due to ingested contents or whether the attendant causes primarily attacked the mucous membrane. Of the lesions met with in the rectum which could be actually made out by inspection with the proctoscope by reflected light or through the sigmoidoscope by direct light neglecting the anal affections were: 1. An ulcer situated in the posterior aspect of the rectum about one and three-quarter inches up or just above the internal sphincter, just opposite the tip of the coccyx, which might be styled the tropical ulcer, seeing its frequency in persons who had resided in the tropics and had been the subjects of intestinal flux. It was single, rounded, punched-out looking, very painful when touched, and gave rise to the neuralgia so often complained of. It was an aggravating complication in the last stages of sprue and in many post-dysenteric conditions. It was easily cured by incisions and in many cases of troublesome intestinal flux the condition would disappear, and what seemed an incurable diarrhœa by drugs was thus readily got rid of. 2. Multiple ulcers, two to three inches from the anus, presenting a greyish dull brown appearance, sometimes with hæmorrhagic margins inclining to an oval shape with their long axes parallel to the length of intestine, were associated with irregular evacuations of a pultaceous consistence sometimes accompanied by blood in the stools, and were due to tertiary syphilis and must be treated accordingly. 3. At the sigmo-rectal pylorus was the situation at which post-dysenteric lesions were chiefly met with. Here they might find one or another of the following conditions: (*a*) an œdema of the mucous membrane. (*b*) The wall of the bowel might be studded with multiple purulent looking collections in the mucous membrane varying from the size of a pin-head to that of a split pea or larger. Associated with these might be one or several ragged ulcers covered with a whitish surface. This condition was met with in relapses of dysentery of a more or less acute nature. (*c*) Multiple ulcers of varying size with angry margins were extremely painful on the attempt being made to pass the sigmoidoscope and accompanied by spasm of the bowel rendering it impossible to push the instrument beyond them. (*d*) Infiltration of the submucous tissue with scars of old ulcers amounting to stricture of the bowel which might become even (*e*) of a fibrous character. 4. The sigmoid flexure itself when any of the lesions in the sigmo-rectal pylorus above enumerated were present was usually in a state of œdema and catarrh. For treatment when the causes of mucus in stools were situated without the bowel wall steps must be taken to deal with them on general surgical principles. When the bowel wall itself was seen to be at fault the treatment depended upon the state of the lesions met with. For general œdema of the mucous surface enemata of warm sea water (not diluted) would be found highly efficacious—that applied also to all states of the rectum associated with excess of mucus; in so-called mucous colitis sea water was serviceable. When the bowel was ulcerated in the neighbourhood of the sigmo-rectal pylorus pure carbolic acid was the most satisfactory application. When there was infiltration of the submucous tissues amounting to a strictured state of the bowel at the sigmo-rectal pylorus, accompanied by intermittent attacks of loose evacuations with a quantity of mucus, it was necessary to treat the stricture. One of the commonest conditions which they had to treat in long-standing intestinal flux succeeding dysentery was one in which after a few days or even a few weeks of apparently healthy evacuation there was a remission consisting of bulky, frequent, and very loose motions, often frothy in character, accompanied by a large quantity of mucus. This condition might last from a few days to a week or two, to be succeeded by apparently normal motions,

THE COMMON COLD: ITS PATHOLOGY AND TREATMENT,

WITH ESPECIAL REFERENCE TO VACCINE THERAPY.[1]

BY R. W. ALLEN, M.D., B.S. LOND.,
CLINICAL PATHOLOGIST, MOUNT VERNON HOSPITAL FOR CONSUMPTION; LATE PATHOLOGIST TO THE ROYAL EYE HOSPITAL AND LATE GULL RESEARCH STUDENT IN PATHOLOGY, GUY'S HOSPITAL.

(Concluded from p. 1594.)

VI.—NATURAL CURE OF COLDS.

THE most striking clinical feature of an acute attack of nasal catarrh is perhaps the excessive mucous secretion, and the question arises as to the causation and function of this.

Causation of increased mucous secretion.—The effect of the application to the nasal mucosa of such chemical irritants as strong ammonia and acrolein is so marked as to favour the view that the increased flow is merely a reflex response to the toxins formed by the infecting organism. It would appear, however, from the following experiments that this is not so. Of the several organisms capable of producing a cold Friedlander's bacillus is the one which incites the most copious secretion. Accordingly a tube of broth was inseminated with a virulent culture of Friedländer's bacillus and incubated at 37° C. for nine days, when the formation of any toxin is, as a rule, at a maximum. The culture was then filtered rapidly through a sterilised porous candle. Some of the clear sterile filtrate was then swabbed over my nasal mucosa, but, so far from an increase, a marked diminution in the amount of mucous secretion was produced for the next few hours.

The next experiment seems equally convincing, as despite the observation of a French observer it seems to show that the bacillus of Friedlander does not produce extracellular toxin, or at all events only in very minute quantity.

Experiment.—20 cubic centimetres of broth were inseminated with a virulent culture and incubated at 37° C. for nine days; rapid filtration through porous candles was carried out and the sterility of the filtrate was ascertained; 10 cubic centimetres of this filtrate were then injected intraperitoneally into a guinea-pig and 5 cubic centimetres into a rat. No rise of temperature or malaise could be detected and repetition of the experiment gave a like result.

Again, if staphylococci and Friedländer's bacillus be planted into the same broth and incubated, the latter will soon kill off the former even if any acid be neutralised with powdered marble as quickly as it is formed by the bacilli. The following table shows this.

TABLE VII.

Period of incubation.	$\frac{\text{Bacilli}}{\text{Staphylococci.}}$	$\frac{\text{Bacilli}}{\text{Staphylococci.}}$
(1) Prior to incubation.	$\frac{1}{1}$	—
8 hours at 37° C.	$\frac{43}{1}$	—
24 hours at 37° C.	$\frac{250}{6}$	—
(2) Prior to incubation.	$\frac{1}{15}$	$\frac{1}{15}$
5 hours at 37° C.	$\frac{7}{1}$	$\frac{7}{1}$
12 hours at 37° C.	$\frac{190}{3}$	$\frac{190}{3}$

Column 2 = acid not neutralised with marble. Column 3 = acid neutralised with marble.

If this lethal action of the bacillus pneumoniæ upon staphylococci be due to extracellular toxin formation, then a similar result should have been obtained in the following experiments, but it was not.

Two tubes of broth were inseminated with equal numbers of bacilli, powdered marble being added to one of them to neutralise any acid formed. After four days' incubation at body heat rapid filtration was performed through sterilised porous candles. Six cubic centimetres of each filtrate were obtained, of which half in each case was heated to 95° C. for 30 minutes to destroy any toxin present. To each of these four tubes three cubic centimetres of broth were added and equal numbers of staphylococci were introduced. After incubation at 37° C. for four and for eight hours the organisms in equal volumes of the several cultures were counted, with the following result:—

Period of incubation.	+A. +T.	+A. −T.	−A +T.	−A. −T.
4 hours	290	330	260	380
8 "	490	510	520	560

A. = acid. T. = toxin.

The differences are so slight as to be within the errors of experiment, and strong confirmation is afforded of the view that the bacillus of Friedlander does not form any extracellular toxin. It would thus appear that the increased mucous secretion is not due to the effects of extracellular toxin formed by the infecting bacilli, but to the mechanical irritation set up by the presence of these foreign bodies in the respiratory tract.

Action of nasal mucus.—Wurtz, Lermoyez, and others have expressed the view that the secretions of the various mucous and serous glands, such as those of the eye, the nose, the uterus, and the vagina, possess bactericidal properties. StClair Thomson and Hewlett[2] studied the action of mucus upon anthrax spores and found no proof of bactericidal action. Klemperer and Park and Wright[3] agreed that the nasal secretion has no bactericidal action. In view of this difference of opinion and the fact that an admirable opportunity presented itself of collecting a large quantity of nasal secretion the following experiment was decided on. From a case of acute nasal catarrh due to the bacillus of Friedländer nasal secretion was being poured out at the rate of from 15 to 20 cubic centimetres per hour. 10 cubic centimetres were collected without difficulty and were at once filtered through a sterile porous candle; 6·7 cubic centimetres of clear slightly alkaline fluid were thus obtained; four sterile test-tubes were taken. Into Tube *a* were placed 3·5 cubic centimetres of filtered nasal mucus; into Tube *b* 3·5 cubic centimetres of a 0·1 per cent. salt solution; into Tube *c* 3·2 cubic centimetres of filtered nasal mucus; and into Tube *d* 3·2 cubic centimetres of a 0·1 per cent. salt solution. Emulsions of 18-hour-old cultures of the bacillus of Friedländer and of staphylococcus aureus were then prepared. Tubes *a* and *b* were then inseminated with equal volumes of the emulsion of Friedländer's bacillus and Tubes *c* and *d* with equal volumes of the staphylococcal emulsions. By means of a sterile platinum loop equal amounts of the several mixtures

TABLE VIII.

A.—For Bacillus of Friedlander, Tubes a and b.

Volumes withdrawn—	Tube *a*, nasal mucus. Number of colonies.	Tube *b*, salt solution. Number of colonies.
After ½ hour.	902	944
" 1 "	520	136

ligament from the front he had no difficulty in enucleating it. There was considerable hæmorrhage, but he was fortunate in that the first suture included the uterine artery, and he had little trouble afterwards. He did not ligate the ovarian artery separately. He sutured up the rest of the cavity with silk sutures.

The PRESIDENT showed the following card specimens: (a) Epithelioma of the Uterus, 9; (b) Adeno-carcinoma of the Uterus, 3; (c) Sarcoma of the Uterus; (d) Fibroid of the Uterus, 14; (e) Adeno-myoma of the Uterus; (f) Carcinoma of the Ovaries; (g) Cyst of the Ovary, 6; (h) Dermoid, 2; (i) Pyosalpinx; (j) Tuberculous Tubes; (k) Tubal Pregnancy; and (l) Hypernephroma.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Sheffield on Nov. 20th, Dr. A. J. Wallace (Liverpool), the President, being in the chair.—Dr. J. W. Martin (Sheffield) exhibited a specimen of Extra-uterine Pregnancy occurring in the left Fallopian tube of a uterus bicornis unicellis. At the abdominal section the left Fallopian tube containing the gestation sac was seen to be attached to the left cornu of a double uterus. The cornu in size and shape resembled the normal corpus uteri. The right horn was represented by a solid structure four inches long and as thick as the little finger; it occupied the sac of a right-sided inguinal hernia. The round ligament and the right appendage could be recognised, but the attachment of the right Fallopian tube to the rudimentary cornu was indistinct.—Dr. J. E. Gemmell (Liverpool) showed a specimen of Primary Epithelioma of the Vagina occurring in a woman aged 40 years. The growth occupied the upper three-fourths of the posterior wall and was freely excised after a preliminary Schuchardt's incision had been made. Microscopically the structure was that of a squamous-celled growth with pronounced mitotic nuclear figures. This feature, together with the absence of cell-nests, pointed to its rapid growth.—Mr. Percival E. Barber (Sheffield) reported a case of Pelvic Hæmatocele due to Carcinoma, simulating Ectopic Gestation. The patient was a single woman, aged 37 years, who complained of severe abdominal pain following a period of three months' amenorrhœa. Under anæsthesia the pouch of Douglas bulged downwards and the examining finger passed readily through very friable tissue into a cavity from which escaped blood clot and broken-down débris. Microscopical examination showed it to be a columnar-celled carcinoma, probably secondary to adeno-carcinoma of the ovary.—Dr. W. E. Fothergill (Manchester) recorded two cases of Gynatresia. The first was that of a girl, aged 14 years, the subject of advanced phthisis, who came under observation on account of pain in the right side and two months' amenorrhœa. Menstruation began at the age of 13 years and was regular for a year, when it ceased. Examination revealed an abdominal tumour reaching to the umbilicus; its lower pole could be felt per vaginam, and to the extreme right of this a crescentic slit represented the os externum of the right half of a double uterus, through which menstruation had occurred for a year. The left half was atresic and distended by retained menstrual fluid which was evacuated. The symptoms were entirely due to the general malady, the hæmatometra being an accidental complication. In the second case, hæmatometra and hæmatocolpus were present in a girl aged 15 years who had never menstruated and had had no menstrual molimina. On evacuating the over-distended bladder an abdominal tumour extending above the umbilicus was defined. There was no vaginal orifice, and the perineum was bulged as by a fœtal head at the end of labour. An incision behind the meatus urinarius through one-third of an inch of very firm tissue evacuated about a gallon of the usual chocolate-coloured fluid. The edges of the vaginal mucosa were secured to the edges of the skin incision. Free drainage was insured by maintaining the sitting posture from the time the patient left the operating table.—Professor R. Favell (Sheffield) narrated a case of Obstructed Labour in a Bicornuate Uterus. The patient, a woman, aged 23 years, had had two children, the last 14 months ago. She gave a history of seven and a half months' amenorrhœa, with more or less constant abdominal pain, and latterly severe hæmorrhage. The physical signs resembled those of an ovarian tumour complicating pregnancy. Abdominal section showed the condition to be due to pregnancy in a uterus bicornis unicellis, the right horn of which was occupied by the fœtus; the left horn, the smaller, contained the placenta. Cæsarean section was performed through a transverse incision and recovery was uneventful.—Dr. Miles H. Phillips (Sheffield) related a case of Apparent Recurrence of a Cervical Fibroid in a patient, x-para, aged 48 years, from whom he had enucleated a cervical fibroid a year previously. The patient returned complaining of pelvic pain and bladder irritability. There was no vaginal discharge or loss of flesh. Examination revealed a bossy tumour in the anterior lip of the cervix in the site of the original growth. Abdominal total hysterectomy was carried out in the event of the tumour proving to be malignant. Microscopically it was to be regarded, however, as a fibro-myoma undergoing myxomatous degeneration.—Mr. Archibald W. Cuff (Sheffield) communicated a short note on the Spontaneous Closure of Ureteral Fistulæ.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on Nov. 24th, Dr. F. J. Smith, Vice-President, being in the chair.—Dr. A. G. Bateman, secretary of the Medical Defence Union, read a paper entitled "Unqualified Practice and the Medical Act of 1858." He reviewed cases taken in the courts under the Act and urged that the medical and legal professions should strive to get proper recognition of the medical practitioners in this country and the abolition of the quack. Dentists and veterinary surgeons were protected against unqualified practice but apparently human beings were not of so much account as animals. Education of the public for their own safety and well-being was necessary.—Sir William H. Allchin (visitor), Dr. F. W. Hewitt, Mr. F. W. Sherwood (recorder of Worcester), Mr. A. D. Cowburn, Dr. S. B. Atkinson, Mr. H. Sweeney, Mr. M. Wimpfheimer, and Mr. R. Burrows, LL.D., joined in the discussion that followed.—Dr. Bateman having briefly replied, the meeting adjourned.

Reviews and Notices of Books.

Quain's Elements of Anatomy. Edited by EDWARD ALBERT SCHÄFER, LL.D., Sc.D., F.R.S., Professor of Physiology and Histology in the University of Edinburgh; JOHNSON SYMINGTON, M.D. Edin., F.R.S., Professor of Anatomy in Queen's College, Belfast; and THOMAS HASTIE BRYCE, M.A., M.D. Edin., Lecturer in Anatomy, University of Glasgow. Eleventh edition. In Four Volumes. Part 1, Vol. III., Neurology. By E. A. SCHÄFER and J. SYMINGTON. With 361 illustrations, many of which are coloured. London: Longmans, Green, and Co. 1908. Pp. 421. Price 15*s.* net.

IN our issue of July 18th, p. 162, we mentioned the subjects which would be contained in the four volumes of "Quain's Elements of Anatomy" and we published a review of Vol. I. (Embryology, by Dr. T. H. Bryce). The next portion of the work in order of publication is the one at present under notice (Part 1 of Vol. III.), embracing the general structure and mode of development of the elements of the nervous system and the special structure of the spinal cord and brain. It will be followed by a second part containing the descriptive anatomy of the nerves and of the sense organs, the two parts together constituting a complete text-book of neurology.

The present volume has been edited and almost entirely rewritten by Professor Schäfer and Professor Symington who have undoubtedly taken the greatest care that the book should be worthy of their names. Needless to say, their labours have been eminently successful, for the book, besides embodying the most recent knowledge on the subject of which it treats, contains an extensive bibliography and is lavishly supplied with illustrations which would be difficult to surpass. The first section, containing an excellent account of the general structure and mode of development of the nervous system, is followed by a detailed account of the structural elements of the nervous system, in which the histological anatomy of nerve cells and nerve fibres, of neuroglia cells and fibres, of nerve endings, and of

That it is a powerful antiseptic is admitted, but a solution of at least 1 in 500 is required before an infecting organism can be destroyed. A few grains daily by the mouth are not likely to reach the nasal mucosa; local application in the form of insufflations proves much more efficacious and will control the excessive discharge. Upon the stomach in such doses as are usually taken in colds it exerts a disturbing influence, while the tinnitus of the ears and headache which it may produce even when combined with hydrobromic acid, are distinctly undesirable results. In the blood it circulates as the chloride, diminishing metabolism by increasing the stability of the oxyhæmoglobin and prejudicially affecting the white blood corpuscles, the phagocytes of the body. Its only utility is as an antipyretic, and fever in these cases is usually conspicuous by its absence. In brief, a more useless drug theoretically could hardly be employed. In practice, these prejudicial effects are masked and even overcome by judicious combination with ammonia, one of the most powerful of stimulators of the heart and respiration. By the influence of this drug upon the vasomotor system a slight balance is perhaps left upon the credit side. It must, however, be admitted that many eminent physicians hold a very different view of the utility of quinine.

The most useful drugs in shortening an attack are perhaps oil of cinnamon and oil of eucalyptus, but these must be used and not dallied with, the doses in the pharmacopœia are much too small. Both these drugs are antiseptic in action and are excreted by all the mucous membranes; they stimulate the heart both reflexly and directly and dilate the blood vessels, thus exerting valuable action upon the vasomotor system; in their action upon the bronchial tubes they are antispasmodic. The first of these drugs should be given in 20-minim doses in milk for each of the first three hours, then every other hour in 15-minim doses for two doses, then three or four hourly in 10-minim doses; if the patient can at once take to bed cure is usually complete in from 36 to 48 hours; in fact, I have seen some remarkable cures of very severe colds in even less time than this and have never seen any ill effects. Oil of eucalyptus requires more care in its use and a pure oil alone should be employed. It is not so pleasant to take as oil of cinnamon and is distinctly less agreeable to those around. To obtain the best results local application should be combined with administration by the mouth. This is done by the addition of five or six drops to boiling water and inhalation of the medicated steam through any suitable inhaler. By the mouth from 10 to 15 minims should be taken every three or four hours upon sugar; oil of the Pinus pumilionis can be also employed in an exactly similar way.

To assist the action of the skin and kidneys the following prescription by Burney Yeo is very useful at bed-time: tct. opii, ♏x.; vin. ipecac., ♏v.; sp. aether. nit., ʒi; liq. ammon. acet., ʒiij; aq. camp. ad ℥iss. Misce et fiat haustus, hora somni sumendus.

These measures may suffice to cut short an attack but should they not the subsequent course taken by the cold will depend upon the organism at work. A correct differential diagnosis will enable one to anticipate subsequent events and provide against them. Should the bacillus septus be at work no complications are as a rule to be anticipated and treatment of the early stages is chiefly symptomatic. Should the sore throat prove troublesome a gargle and spraying by means of an atomiser of the following composition is useful: pot. chlorat, gr. x.; liq. ferri perchlor., ♏ xv.; glycerini, ♏ xxx.; aq. ad ℥ i. Misce et fiat gargarisma; quartis horis utenda. In my experience this mixture ceases to be of benefit after about 24 hours and a change to the following is advisable: pot. chloraf, gr. x.; A. hydrochlor. dil., ♏ x.; syrup, ʒ i.; aq. ad ℥ i. M. et fiat gargarisma; quartis horis utenda. Should the *fourth* stage, that of thick tenacious mucus secretion, prove troublesome, intranasal douches will afford considerable relief. If the micrococcus catarrhalis be responsible for the attack the symptoms and complications may be much more severe. Headache, facial neuralgia, and cough may cause considerable discomfort; for the last of these I used to prescribe glycoheroin, but it did not prove very satisfactory, and I have found a new drug, pyramidon and its salts, much more useful; if there be any pyrexia five-grain doses in cachets every four hours of the pyramidon acid salicylate are perhaps best, but if the cough be bad and rhonchi are heard in the chest then similar doses at the same intervals of the acid camphorate are to be recommended.

Infection of the Eustachian tube and middle ear is by no means infrequent and may cause considerable discomfort. Applications of dry heat to the external ear are of service; the results of vaccine therapy though satisfactory are somewhat slow in appearing.

Should the trachea and bronchi be badly affected a tedious convalescence, with possible disturbance of the circulatory and digestive systems, is almost inevitable. Here a single injection of from 250,000,000 to 500,000,000 of a catarrhalis vaccine often acts in a manner which is almost marvellous; several cases of the most incessant cough have secured perfect freedom in less than 24 hours.

As regards the influenza bacillus I have nothing to say, as it appears to have been conspicuous by its absence during the past four years, and my consequent experience is *nil*. Horder, however, in the number of the *Practitioner* for May, 1908, records the results of treatment of a case of chronic ulcerative endocarditis due to the influenza bacillus by means of the corresponding vaccine. The favourable result therein obtained holds out good hopes that vaccine therapy might prove of service in dealing with acute attacks of catarrh due to this bacillus.

In the case of Friedländer's bacillus chronicity is most to be feared, but infection of the Eustachian tube and middle ear is by no means unlikely. Apart from vaccine therapy I know of no useful measure in dealing with these complications.

(*b*) *Of chronic colds.*—These all seem to be due to the bacillus of Friedländer. In each of two cases several operations had previously been performed on the nose and throat but without effecting relief from the perpetual cold for more than a few weeks; nevertheless, where spurs or deflections or polypi be present in the nose or enlarged tonsils in the throat, surgical interference should first be sought and adequate airway obtained. The most distressing symptom is a continual "stuffiness" of the nose. This condition is due not so much to excess of nasal secretion as to reflex turgidity of the nasal mucosa. That it is reflex in origin is shown by the instantaneous relief afforded various subjects on getting into a cold bath, by going out of a hot room into a cold, or by even leaning the head to one side. This would suggest that permanent relief might be secured by cauterisation of the mucosa over a certain area, as in the instance of one of the forms of asthma. So far as I am aware this has never been tried. Another way is by destroying the organisms which set up the reflex. Intranasal douches are useful but seem hardly sufficient for this purpose. Combination of this with injections of a vaccine prepared from the organisms isolated from the patient has proved very satisfactory.

Details of my work upon the vaccine-therapy of colds will now be given.

VIII.—THE VACCINE THERAPY OF COLDS.

A. Experiment. To determine whether there are opsonins for the organisms in question—viz., bacillus septus, micrococcus catarrhalis, and bacillus Friedländer.—Two specimens of blood serum were taken and each was divided into two portions, one of these being heated for one hour at 60° C. to destroy any opsonin which might be present. The sera, unheated and heated, were then employed as usual in opsonic determinations and films prepared. The counts obtained for 50 polymorphonuclear leucocytes were as follows:—

(*a*) Organism employed: micrococcus catarrhalis.

Serum I.		Serum II.	
Unheated.	Heated.	Unheated.	Heated.
250 in 50	0 in 50.	260 in 50	0 in 50

The presence of an opsonin for this organism, which is all destroyed by heating for one hour at 60° C., is thus demonstrated.

(*b*) Organism employed: bacillus septus.

Serum I.		Serum II.	
Unheated.	Heated.	Unheated.	Heated.
68 in 50	23 in 50	67 in 50	23 in 50

which proves the presence of an opsonin for bacillus septus, which, however, is *not all* destroyed by heating for one hour be designated the "supraliminal" or ordinary consciousness. In illustration of this conception the range of psychical processes is compared to the spectrum of the sun's rays. It is familiar that beyond the visible spectrum there are the heat rays at the red or lower end, the actinic and other rays at the violet end; so it is suggested that in the "conscious spectrum" there are subliminal faculties beyond the lower or organic end and beyond the higher or intellectual end. The object of Mr. Myers's work was to present and to examine the various kinds of evidence on which this general conception was based.

The first subject considered in the light of this view of conscious activities is that of "Disintegrations of Personality." A psychological study is given of certain forms of mental alienation, including those of the "fixed idea," of double personality, and of secondary personality. Next, genius is considered, and the ingenious hypothesis is offered that the inspiration of genius is due to the capacity of utilising a wider range of faculties than in the ordinary person and to "subliminal uprushes" into actual consciousness. Various personal experiences of great men are quoted in support of this idea. Genius is thus supposed to be due to the subliminal mentation coinciding with, and supplementing, the supraliminal without changing the apparent phase of personality. Hypnotism, on the other hand, is regarded as the result of subliminal operations changing the apparent phase of personality from the state of waking in the direction of trance, while the phenomena called sensory or motor automatism result when the subliminal forces itself up through the supraliminal without amalgamation as in crystal vision and automatic writing.

A chapter is devoted to a study of sleep and dreams and an explanation of the genesis of dreams in the light of the above general conception is developed. It is suggested that the sleeping consciousness is capable of telæsthetic and telepathic properties, perhaps to a greater degree than the waking. It is further assumed that human life possesses two aspects, a material phase, to which the organism reacts, and a spiritual or cosmic phase. The subliminal self is conceived as in the main directing the sleeping period in which the organism may draw in energy from the spiritual world or "expatiate in the exercise of supernormal powers—telepathy, telæsthesia, ecstasy."

The subject of hypnotism is next considered at some length, the history from the days of Mesmer to the present time is lucidly outlined and the nature of the phenomena associated with the hypnotic state is discussed. Mr. Myers was in the main in agreement with the Bernheim or Nancy School, and regarded Charcot's work on hypnotism as having retarded rather than helped its progress. He recognised the paramount importance of suggestion in regard to hypnosis and defined suggestion in terms of his own hypothesis as "successful appeal to the subliminal self." He believed that the possibilities of advance opened up by hypnotism were very great, not only as a therapeutic agent but also as a means for educating and evolving human faculties by enlarging the sphere of application of subliminal mental activities.

Sensory automatisms, which are defined as "the products of inner vision or inner audition externalised into quasi-percepts," form the subject of the next chapter. Various phenomena, such as those of linked sensation or synæsthesiæ, memory images, hallucinations, and the appearance of phantasms or visitations, are considered. The importance of telepathy in connexion with some of these phenomena is frequently emphasised and two alternative views are offered to explain the phenomenon of the appearance of phantasms, one that of "telepathic impact," the other that of "psychical invasion," which supposes that the agent in some way causes a modification of some definite portion of space in such a way as to give the impression of an apparition to one or more percipients.

The more complex, though cognate, subject of phantasms of the dead forms the subject of the next chapter. The question is obviously one of paramount importance in connexion with the main thesis of the survival of personality after bodily death. The conditions to which such phenomena must conform in order to be attributable to the influence of a discarnate mind are laid down. Various recorded instances are analysed and it is contended that the general nature of such manifestations is in conformity with those of spontaneous telepathy during life and with those of phantasms of the living and that they fall into three groups: actual apparitions, emotional and motor manifestations, and definite intellectual messages.

Motor automatism, or the conveyance of messages by movements of limbs, hand, or tongue initiated by inner motor impulses beyond the conscious will, forms the subject of the next chapter. In this connexion muscle reading (often wrongly called mind reading), automatic writing, and automatic speech are discussed in detail and the view is expressed that such phenomena may be due to an actual "psychical invasion" of the percipient by some other personality. This idea is further developed in the next chapter which is devoted to a consideration of trance, possession, and ecstasy. Possession is thus regarded as a more developed form of motor automatism in which there is a more or less complete substitution of personality. Some important recorded cases of possession are discussed. In an epilogue the relation of these phenomena to religious beliefs is discussed and hope is expressed of the future advances to be made by careful research on the lines of inquiry outlined in this book.

It is impossible to study the work of the lamented and gifted author without admiration for his enthusiasm and for the careful, scientific, and laborious analysis to which he subjected the complex data at his disposal. The charm of his literary style, the ingenious character of his speculations, and the fascination which the subject of the survival of personality has always possessed for the thoughtful minds of all ages combine to render the volume one of great interest. The result is to leave us in a receptive, though not a convinced, state of mind in regard to many of the interesting phenomena and speculations with which it is concerned.

The Story of a Lifetime. By Lady PRIESTLEY. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1908. Pp. 334. Price 12*s.* 6*d.*

Lady Priestley tells us in the preface to her book that it was originally written some five years ago solely for family reading. A few copies only were printed but the book soon became known and many applications were made both to see the book and to review it. At first Lady Priestley refused to make it public but at length she yielded, and we congratulate her on her resolve; for the result is that the reading public is now in possession of a book of reminiscences which are, unlike some reminiscences, not boring, not twaddly, but full of interest, especially to those who take delight in literary or artistic matters.

Eliza Priestley was a twin daughter of Robert Chambers, the well-known Edinburgh publisher, so she was brought up in the Edinburgh of the "forties" and "fifties" and was a member of the remarkable literary and artistic circle of those days which then made Edinburgh famous. John Brown, Noel Paton, George Combe, Simpson, Aytoun, Theodore Martin, are only a few among the names which appear in Lady Priestley's recollections of her childhood. Bulwer Lytton, immortalised as much by "George de Barnwell" as by "Eugene Aram," was a frequent visitor at the

2, 6, and 9 were identical in all their reactions. Despite this the vaccine employed for Case 1 with complete success was quite inefficient when used upon Case 9. Before injection with 300,000,000 dead organisms the index stood at 1·45, a week later it was only 1·0, yet a week later it was only 1·36. This might, of course, have indicated a very long negative phase, but a repetition of the injection with a like dose of a vaccine prepared from the patient's own organism gave a quite satisfactory result.

(*d*) *The results of vaccine therapy.*—(1) In chronic colds; (2) in *acute colds.* *15 of the cases underwent vaccine* therapy. Chronic colds: Cases 1, 16, 31, 34, and 42. Acute colds: Cases 8, 9, 17, 19, 29, 30, 32, 37, 38, and 41. The results may be tabulated thus.

1. Chronic Colds.

CASE 1.—
nasal catarrh for 12 years with about 20 acute
—21 months.
—Eight.

Result.—There was disappearance of the bacillus of Friedlander after three injections. Complete immunity from acute attacks secured for 15 months by means of injections of the vaccines of the several "cold organisms, then one acute attack due to the micrococcus catarrhalis.

CASE 16.—
Description.—Chronic naso-pharyngeal and tracheal catarrh for 17

# Reports and Analytical Records
FROM
THE LANCET LABORATORY.

(1) SPARTAN BISCUITS; AND (2) APAX BISCUITS.

(HUNTLEY AND PALMER, READING.)

1. THE Spartan biscuit represents a form of food which has been considerably enriched with protein. Our analysis shows that the protein amounts to 21·16 per cent., the other constituents representing ordinary wheaten flour. The mineral matter amounted to 1·30 per cent. and the moisture to 3·40 per cent. The biscuit is satisfactorily dry and crisp and is thoroughly cooked. As a source of food containing a trustworthy proportion of nutrient substance the biscuits are satisfactory, providing reparative materials as well as those elements which support the energy of the body. 2. Apax biscuits also represent a high protein value, the protein amounting, according to our analysis, to 27·34 per cent. This addition obviously diminishes the proportion of carbohydrates, a fact which has suggested their use by persons inclined to corpulency. Under the microscope branny particles were easily observed. The Apax biscuit is undoubtedly nourishing while it is also calculated to help peristaltic action.

COLVO.

(RISICCOL, LIMITED, 31 AND 32, BUDGE-ROW, LONDON, E.C.)

Colvo is the name given to a powder which contains, according to our analysis, 40·50 per cent. of cod-liver oil. This large percentage of oil present in a preparation which is in the form of powder, dry and almost dusty, is remarkable. The absorbent is magnesia. The powder may be administered in many ways without offending the susceptibilities of those who find ordinary cod-liver oil repulsive. We have also examined biscuits which, according to our analysis, contained over 20 per cent. of oil, the oil again being obscured in the same way. The preparations represent a satisfactory attempt at meeting the chief objection to a well-known valuable therapeutic agent.

GINORA (BITTERS).

RAYS, LIMITED, OVAL-STREET, GREAT PORTLAND-STREET, LONDON, W.)

According to our analysis, and chemically speaking, this is a dilute alcoholic solution of well-known bitters. It contains 8·51 per cent. of extractives, consisting chiefly of bitter principles. The alcohol amounted to 17·17 per cent. per volume. Like many well-known bitters it encourages the secretion of digestive juices and stimulates the appetite.

CAPE COLONY WINES AND BRANDIES.

(HENRY C. COLLINSON, LIMITED, 9, CASTLE-STREET, CAPE TOWN; LONDON AGENCY, 38, MINCING-LANE, E.C.)

We have from time to time had occasion to examine the wines produced in Cape Colony, and it is quite evident that the methods of cultivation there are now meeting with a success approaching that obtained in other countries. We have received, for example, a series of samples from Cape Town recently which comprised wines of the type of Rhine wines, Medoc wines, Burgundy wines, Oporto wines, and Jerez wines, and amongst these also we may mention some brandies which are promising in character. We cannot deal with all the samples referred to but will select a few which we regard as good examples. The wine known as Hermitage, for example, is distinctly of the Bordeaux character, light as regards alcohol, non-acid, and pleasant to the taste. On analysis this wine gave the following results: alcohol by volume, 13·43 per cent.; extractives, 2·32 per cent.; mineral matter, 0·22 per cent.; volatile acidity reckoned as acetic acid, 0·12 per cent.; and fixed acidity reckoned as tartaric acid, 0·525 per cent. Pontac again closely resembles a burgundy—that is, a robust, almost purple-coloured, wine with good "flower," as connoisseurs would say. It contained 17·17 per cent. by volume of alcohol, 3·65 per cent. of extractives, a volatile acidity of 0·18 per cent. calculated as acetic acid, and a fixed acidity of 0·55 per cent. calculated as tartaric acid. The Kimberley Club sherry and the Cape port we cannot endorse as having the æsthetic characters of the famous wines of Jerez and Oporto respectively, although we have no doubt that they are pure genuine wines. Drakenstein we regard favourably as an agreeable light wine resembling Rhine wine, though somewhat heavier in respect of alcohol, of which it contained 14·37 per cent. by volume. The extractives amounted to only 1·61 per cent., the volatile acidity to 0·10 per cent., and the fixed acidity to 0·54 per cent. As to Cape brandies, those known as V.S.O.P. and fine old liqueur are excellent. They have the characters of a well-matured wine spirit, and analysis shows a remarkably high proportion of ethers. The amounts as a matter of fact varied from 200 to 212 parts per 100,000 parts of alcohol present. The quantity of furfural was comparatively small. The V.S.O.P. showed greater age than the other samples and was really an excellent brandy. The three star brandy was less classic in character and compared with the others possessed a flavour and odour which indicated youth rather than age. On the whole, the wine products of Cape Colony are developing along satisfactory lines and their quality and characters are improving so obviously that before long they may dare to compete with the similar products of historic countries.

LACTOBACILLINE.

(LA SOCIÉTÉ "LE FERMENT," 77, RUE DENERT-ROCHEREAU, PARIS.)

We have received from the above Société "Le Ferment" samples of their compressed lactobacilline tablets which are said to contain two species of the lactic germ, one of Eastern and the other of European origin. In other words, lactobacilline is a pure culture of lactic organisms which may be employed in various forms—tablets, fluid, and so forth—in the treatment of gastro-intestinal affections. The preparations are the practical outcome of Metchnikoff's view that nascent lactic acid prevents a putrefactive action in the intestine and therefore wards off certain toxic effects which otherwise may arise. In a way, therefore, lactobacilline may be said to have an antiseptic action, inasmuch as the lactic organisms contained in it develop lactic acid which is antagonistic to the putrefactive organisms of the colon. We found the tablet to be active, for on cultivating some of it crushed in milk, the transformation of the milk sugar into lactic acid was abundantly proved.

AMBORA SOAPS.

(THE AMBORA SOAP WORKS, 101, FINSBURY-PAVEMENT, LONDON, E.C.)

The presence of free ammonia in soap is certain to assist very materially its action as a detergent and is especially applicable in cases where coarse dirt is required to be removed. Ambora, according to our examination, is a white soap paste, giving off a strong smell of ammonia. It acts most effectually in removing greasy impurities however gross. We also examined a toilet ambora soap which is particularly applicable for use in hard water. The list also includes an ordinary bar soap conspicuous for its grease-removing qualities, and a disinfectant soap containing an agreeable antiseptic oil. The products are all excellent hygienic agents.

THE HERCULES PATENT MEAT JUICE PRESS.

(AGENTS, 85, QUEEN VICTORIA-STREET, LONDON, E.C.)

This handy little press, while compact, is also, we find, most effective. It consists of a small screw press, the pressure being exerted upon a series of corrugated discs, between which small pieces of raw meat are placed. The

2, 6, and 9 were identical in all their reactions. Despite this the vaccine employed for Case 1 with complete success was quite inefficient when used upon Case 9. Before injection with 300,000,000 dead organisms the index stood at 1·45, a week later it was only 1·0, yet a week later it was only 1·36. This might, of course, have indicated a very long negative phase, but a repetition of the injection with a like dose of a vaccine prepared from the patient's own organism gave a quite satisfactory result.

(d) *The results of vaccine therapy.*—(1) In chronic colds; (2) in acute colds. 15 of the cases underwent vaccine therapy. Chronic colds: Cases 1, 16, 31, 34, and 42. Acute colds: Cases 8, 9, 17, 19, 29, 30, 32, 37, 38, and 41. The results may be tabulated thus.

1. *Chronic Colds.*

CASE 1.—

Description.—Chronic nasal catarrh for 12 years with about 20 acute exacerbations every year.

Duration of treatment.—21 months.

Number of injections.—Eight.

Result.—There was disappearance of the bacillus of Friedländer after three injections. Complete immunity from acute attacks secured for 15 months by means of injections of the vaccines of the several "cold" organisms, then one acute attack due to the micrococcus catarrhalis.

CASE 16.—

Description.—Chronic naso-pharyngeal and tracheal catarrh for 17

minimum, while avoiding any heating effects, as would be unavoidable in the case of a continued operation. The self-induction coil is directly coupled to a resonance coil R, tuned to the former, and from the terminals of which the current is supplied to eight x ray bulbs, which are made to give out a uniform and steady radiation, generating at two metres' distance, in accordance with Dr. Holzknecht's experiences, a homogeneously penetrative field of radiation of very high intensity. As seen from Fig. 2 each of the x ray bulbs constructed by Bauer comprises two cathodes and a double anti-cathode so as to give out two beams of rays and to cause in the case of an eight-fold operation, as represented in the figure, an aggregate of 16 beams to act on the body. The apparatus, as constructed by a well-known German electrical company, comprises a closed under-frame supporting the two coils R and S, and from which part of the induction coil is allowed to project. The point of the resonance coil during operation gives out electrical discharges of extraordinary intensity, being 1·5 metres in length and of the thickness of an arm. The operator obviously is able to increase the evolution of energy by adding further Leyden jars. The results so far obtained seem to be uniformly satisfactory, and though a definite judgment cannot yet be formed the new process seems to justify the most sanguine hopes.

Berlin. ALFRED GRADENWITZ.

MEDICINE AND THE LAW.

The Engagement of Nurses for Confinements.

IN the Bristol county court a few weeks ago a case was decided by his honour Judge Austin which is of considerable importance to nurses. The facts of the case were as follows. In January last the defendant's wife wrote to the plaintiff, a certificated monthly nurse, that she was expecting to have a baby about the beginning of June and asking her if she would be free at that time. Correspondence passed by which the date at which the plaintiff would be wanted was fixed as "about the last week in May, or the beginning of June," and the plaintiff was definitely engaged for a month commencing at that period. In April the defendant's wife suffered from kidney trouble, and on the advice of a specialist labour was induced on April 28th and the baby was born on May 2nd. At that date the plaintiff was engaged on another case and another nurse had to be engaged. On May 4th the defendant wrote to the plaintiff informing her of the premature birth of the child and telling her "that her services would not be required next month." To this the plaintiff replied that she would see what could be arranged and would try to obtain another case. She was, however, unable to do so, and at the end of June wrote to the defendant informing him of the fact and claiming her agreed fees for the month. As the defendant would not pay the plaintiff brought an action against him, claiming as damages for the breach of her contract the amount of her fees. At the hearing it was argued on her behalf that the contract was an absolute contract for the nurse to keep herself free to render certain services for a month from the agreed time and that she had fulfilled her part of the contract by keeping herself free. It was further argued that the happening of the birth of the child at an earlier date was not such an occurrence as would render the performance of the contract impossible, and that the contract being a positive one there could not be imported into it a condition that because of the birth not happening at the exact date expected the defendant was freed from his liability to pay. The case of Heine Bay Company *v.* Hutton was quoted in furtherance of this argument. This was a case arising out of the postponement of the naval review at Spithead in 1902 owing to the illness of the King. In this case the plaintiffs agreed to let the defendant a pleasure steamer "for the purpose of viewing the naval review and for a day's cruise round the fleet," and it was held that the plaintiffs were able to recover, as the risk was the defendant's alone, and, secondly, the happening of the naval review was not the sole basis of the contract, so that there had not been a total failure of consideration or a total destruction of the subject matter of the contract. Another argument was that if nurses are going to be placed in the position of being liable to lose the whole of their fees through the happening of events over which they have no control it will work a very great and serious hardship and make it almost impossible for them to earn a living at all. The judge, however, held that the basis of such contracts must be taken to be the birth of the child about the calculated time, and that as in this case this had taken place beforehand, owing to no fault of either party, the contract was off at the date of the birth, and he gave judgment for the defendant with costs. It is submitted that his honour was correct in this view for the following reasons. First, as regards the happening of the birth being the basis of the contract, this must be so, since but for the mutual expectation of the birth of the child at the calculated time there would have been no contract whatever made. Once this is admitted the rest follows, for the law relating to contracts of an executory nature has been settled by a well-known case, Taylor *v.* Caldwell, the principle of which is that where the performance of a contract becomes impossible from some cause for which neither party is responsible and the party sued has not warranted that the event, the non-occurrence of which has caused the contract not to be capable of performance, should take place, then both parties are relieved from the performance of the contract. This has been extended by recent cases, notably Krell *v.* Henry, a case arising out of the failure of the procession in London to take place on the advertised date in June, 1902, owing to the King's illness. In this case the defendant had agreed in writing to take rooms in Pall Mall for the dates on which the procession had been fixed, but no express reference to the procession was made, though both parties were aware of the reason for the rooms being taken on those dates and a deposit was paid by the defendant. As the procession did not take place the defendant refused to pay the balance for the rooms, and it was decided in the Court of Appeal by Lords Justices Vaughan Williams, Romer, and Stirling that the plaintiff was not entitled to receive the balance. In the course of his judgment Lord Justice Vaughan Williams said: "I think you have to ascertain, not necessarily from the terms of the contract, but, if required, from necessary inferences drawn from surrounding circumstances recognised by both contracting parties, what is the subject of the contract and then to ask the question whether that substantial contract needs for its foundation the assumption of the existence of a particular state of things. If it does this will limit the operation of the general words, and in such case, if the contract becomes impossible of performance by reason of the non-existence of the state of things assumed by both contracting parties as the foundation of the contract, there will be no breach of the contract thus limited." Also it was decided that "each party must rest in the position in which he is found to be when the event occurs which makes the contract impossible of performance, unless there is something special in the terms of the contract which gives one or other of the parties a different right." On these grounds therefore it must be taken to be correct law that in the event of the birth of a baby at a time other than that arrived at by calculation, then, subject to the following qualifications, the nurse will not be able to recover by action any fees at all unless she is free and able to render the usual services. The qualifications are, first, that if the happening of the birth of the child at a wrong date was the direct result of some serious act of carelessness, wrongful behaviour, or negligence on the part of the patient, or probably also of the patient's husband, the nurse would be able to recover her fees; secondly, she would also be able to recover her fees if she had specially contracted that she was to have her fees unless prevented from attending to the case through some fault of her own. This last appears to be the only way out of a difficulty which certainly does entail hardship on nurses, and the suggestion put forward is that on being engaged for a case the nurse should write a letter to the prospective patient containing a clause on the following lines:—

> I wish to say, also, that as it is impossible to be certain in these cases of freedom from accidents I shall expect, as is usual, to receive my fees (or part of them) if from any cause the baby is born at a different time from that which we expect, and I am thereby prevented from coming to you.

This would protect nurses from losing all their fees in cases of accidents to their patients, miscarriages, or miscalculations of dates, but would not cover acts of negligence on their parts or help them if they choose to take overlapping cases. Their only other remedy is to rely upon their patients' generosity.

B. In chronic colds.—Of the four cases of truly chronic colds the treatment of one was recognised at the beginning as likely to prove very difficult from the presence of complications and probable secondary infections. It is still under treatment, and I am hopeful of ultimate success. One has been absolutely cured, a second practically so, and the third greatly benefited, and in all acute exacerbations have been obviated. Injections in the case of chronic colds should, I think, be controlled by determinations wherever possible of the opsonic index; if the condition be one of chronic tracheitis this can hardly be done as the infection is usually a mixed one, unless the index be taken towards the micrococcus catarrhalis alone. Doses of 500 millions of a vaccine of the mixed organisms obtained from a 12-hours' culture on blood-agar of the tracheal mucus may be employed in cases of chronic tracheitis.

In chronic nasal catarrh secondary infection may be present, but the first thing to be done is to get rid of the bacillus of Friedländer by injections controlled by the index and then to deal with the secondary infection.

It may here be remarked parenthetically that it is quite possible that in certain cases of chronic nasal catarrh with involvement of the various accessory sinuses the bacillus of Friedländer may have disappeared by the time the case is seen and secondary infection by staphylococci, streptococci, pneumococci, &c., alone be present. I have not yet met with such a case, but am quite prepared to do so.

SUMMARY.

1. It has been shown that there are at least five organisms capable of the production of an attack of acute nasal catarrh —viz.: (1) the bacillus influenzæ; (2) the bacillus septus; (3) the bacillus of Friedländer; (4) the micrococcus catarrhalis; and (5) the micrococcus paratetragenus. 2. These may be present in the naso-pharyngeal space in a certain percentage of cases which exhibit no pathological features; increase of virulence and lowered resistance of the tissues may then light them up into activity. In other cases the infection is one from without. 3. Each organism produces its own type of cold and a differential diagnosis of the organism is possible from a consideration of the clinical features; this is more difficult should the infection be à multiple one. 4. This differential diagnosis is of considerable value both in prognosis and in treatment. 5. Chronic nasal catarrh is probably always due to infection by the bacillus of Friedländer, unless the Eustachian tube and middle ear be involved by the micrococcus catarrhalis; chronic tracheal catarrh to infection by the micrococcus catarrhalis or micrococcus paratetragenus to which secondary infection by staphylococci, streptococci, pneumococci, and other pathogenic organisms may be superadded. 6. For infection local defect of opsonin and for cure increase of opsonin are probably necessary conditions. 7. By means of the injection of the corresponding bacterial vaccines an attack of acute cold due to any given organism or organisms can be considerably shortened and complications be probably prevented. 8. In a similar manner chronic infections may be cured. 9. By injection of the vaccines of the several organisms in appropriate doses and at appropriate intervals considerable if not complete immunity against future attacks of acute cold may be secured. In those who are very susceptible and fall victims to every epidemic that may occur, the best procedure probably is systematic immunisation every four to six months against all the "cold" organisms and special immunisation against the particular organism or organisms which may be responsible for the appearance of subsequent epidemics against which protection is desired.

Wimpole-street, W.

THE ROYAL DEVON AND EXETER HOSPITAL, EXETER: ALTERATION OF RULES.—At a special meeting of the court of governors of the Royal Devon and Exeter Hospital held on Nov. 26th it was decided to alter the statutes of the institution so as to enable the anæsthetists, on their retirement at the expiration of their five years' service, to be eligible for re-appointment up to the age of 50 years. It was further determined that "the medical registrar and pathologist shall retire at the expiration of five years from the date of his appointment but shall be eligible for re-election up to the age of 50 years."

PROPHYLAXIS IN ACIDOSIS FOLLOWING ANÆSTHESIA.

BY F. HERBERT WALLACE, M.R.C.S. ENG., L.R.C.P. LOND.,
ANÆSTHETIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM;

AND

E. GILLESPIE, M.B. GLASG., F.R.C.S. ENG.,
SURGICAL REGISTRAR, PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.

OWING to the prominence which has been given lately to the condition of acidosis occurring after the administration of anæsthetics, we have during the last six months carried out an investigation, thanks to the generosity of our surgical colleagues, with a view to ascertain the value of the two remedies suggested—sodium bicarbonate by Beesley and glucose by Beddard. The first series of cases (127) was taken in order to found a basis for comparison with the treated cases and also with a view of establishing the personal equation, both in the administration of anæsthetics and in the examination of the urine. The hospital routine method of preparation—1 ounce of castor oil the night before and a soap enema on the morning of the operation—was followed. The urine, before, in each case was that passed just before operation, and in the case of the women it was removed by catheter. The after specimen was the first passed after the operation, the women being again catheterised. The urine was examined 18 hours later. The anæsthetic, duration of operation, and after-results, especially vomiting, were noted. The method of determining the presence of acetone was that described by Jackson Taylor and confirmed by Weyl's reaction.

Vomiting.—The terms primary and secondary vomiting are intended to convey—primary, any sickness occurring in the first 12 hours after operation, and secondary, any sickness occurring later. Marked vomiting means sickness lasting more than 24 hours.

First Series:—

	No. of cases.	Per cent.
Total number	127	—
Cases showing acetone in urine—		
Before operation	32	25·2
After operation	78	60·4
Cases of primary vomiting	69	54·3
Cases of secondary vomiting	49	30·0
Of which acetone was present in	39	89·0
Marked vomiting lasting over 24 hours	17	13·4
The acetone reaction was obtained in	15	89·0

The two cases in which no reaction was obtained were both of pyonephrosis—one case was of nephrectomy and the other cystoscopy; the sickness in each case lasted 30 hours. 42 per cent. of the patients with albumin in their urine after operation passed acetone. 15·8 per cent. of these had secondary vomiting—in one case of cataract in a boy lasting 72 hours, assuming a typical case of acid poisoning (details will be found in Case 3). There were 10 cases of secondary vomiting without acetone in the urine. Only 2 of these were marked—the aforementioned cases of pyonephrosis. Cases in which acetone was present in the urine after operation without any symptoms were 49, or 30 per cent. There were 47 septic cases; of these, 30 had traces of acetone after operation and *10* passed acetone before and after operation. Of the malignant cases, 8 had acetone after operation and 4 passed acetone before and after operation.

Second series.—These patients were treated with half-drachm doses of sodium bicarbonate at four-hourly intervals —in all half an ounce—the last dose being given four hours before operation.

	No. of cases.	Per cent.
Total number	73	—
Cases showing acetone in urine—		
Before operation	15	25·4
After operation	39	53·4
Cases of primary vomiting	49	67·0
Cases of secondary vomiting	25	34·2
Acetone was present	22	88·0
Marked vomiting	9	12·0
Acetone reaction obtained in	8	88·0

(The single exception being a case of varicose veins.)

minimum, while avoiding any heating effects, as would be unavoidable in the case of a continued operation. The self-induction coil is directly coupled to a resonance coil R, tuned to the former, and from the terminals of which the current is supplied to eight x ray bulbs, which are made to give out a uniform and steady radiation, generating at two metres' distance, in accordance with Dr. Holzknecht's experiences, a homogeneously penetrative field of radiation of very high intensity. As seen from Fig. 2 each of the x ray bulbs constructed by Bauer comprises two cathodes and a double anti-cathode so as to give out two beams of rays and to cause in the case of an eight-fold operation, as represented in the figure, an aggregate of 16 beams to act on the body. The apparatus, as constructed by a well-known German electrical company, comprises a closed under-frame supporting the two coils R and S, and from which part of the induction coil is allowed to project. The point of the resonance coil during operation gives out electrical discharges of extraordinary intensity, being 1·5 metres in length and of the thickness of an arm. The operator obviously is able to increase the evolution of energy by adding further Leyden jars. The results so far obtained seem to be uniformly satisfactory, and though a definite judgment cannot yet be formed the new process seems to justify the most sanguine hopes.

Berlin. ALFRED GRADENWITZ.

MEDICINE AND THE LAW.

The Engagement of Nurses for Confinements.

IN the Bristol county court a few weeks ago a case was decided by his honour Judge Austin which is of considerable importance to nurses. The facts of the case were as follows. In January last the defendant's wife wrote to the plaintiff, a certificated monthly nurse, that she was expecting to have a baby about the beginning of June and asking her if she would be free at that time. Correspondence passed by which the date at which the plaintiff would be wanted was fixed as "about the last week in May, or the beginning of June," and the plaintiff was definitely engaged for a month commencing at that period. In April the defendant's wife suffered from kidney trouble, and on the advice of a specialist labour was induced on April 28th and the baby was born on May 2nd. At that date the plaintiff was engaged on another case and another nurse had to be engaged. On May 4th the defendant wrote to the plaintiff informing her of the premature birth of the child and telling her "that her services would not be required next month." To this the plaintiff replied that she would see what could be arranged and would try to obtain another case. She was, however, unable to do so, and at the end of June wrote to the defendant informing him of the fact and claiming her agreed fees for the month. As the defendant would not pay the plaintiff brought an action against him, claiming as damages for the breach of her contract the amount of her fees. At the hearing it was argued on her behalf that the contract was an absolute contract for the nurse to keep herself free to render certain services for a month from the agreed time and that she had fulfilled her part of the contract by keeping herself free. It was further argued that the happening of the birth of the child at an earlier date was not such an occurrence as would render the performance of the contract impossible, and that the contract being a positive one there could not be imported into it a condition that because of the birth not happening at the exact date expected the defendant was freed from his liability to pay. The case of Herne Bay Company *v.* Hutton was quoted in furtherance of this argument. This was a case arising out of the postponement of the naval review at Spithead in 1902 owing to the illness of the King. In this case the plaintiffs agreed to let the defendant a pleasure steamer "for the purpose of viewing the naval review and for a day's cruise round the fleet," and it was held that the plaintiffs were able to recover, as the risk was the defendant's alone, and, secondly, the happening of the naval review was not the sole basis of the contract, so that there had not been a total failure of consideration or a total destruction of the subject matter of the contract. Another argument was that if nurses are going to be placed in the position of being liable to lose the whole of their fees through the happening of events over which they have no control it will work a very great and serious hardship and make it almost impossible for them to earn a living at all. The judge, however, held that the basis of such contracts must be taken to be the birth of the child about the calculated time, and that as in this case this had taken place beforehand, owing to no fault of either party, the contract was off at the date of the birth, and he gave judgment for the defendant with costs. It is submitted that his honour was correct in this view for the following reasons. First, as regards the happening of the birth being the basis of the contract, this must be so, since but for the mutual expectation of the birth of the child at the calculated time there would have been no contract whatever made. Once this is admitted the rest follows, for the law relating to contracts of an executory nature has been settled by a well-known case, Taylor *v.* Caldwell, the principle of which is that where the performance of a contract becomes impossible from some cause for which neither party is responsible and the party sued has not warranted that the event, the non-occurrence of which has caused the contract not to be capable of performance, should take place, then both parties are relieved from the performance of the contract. This has been extended by recent cases, notably Krell *v.* Henry, a case arising out of the failure of the procession in London to take place on the advertised date in June, 1902, owing to the King's illness. In this case the defendant had agreed in writing to take rooms in Pall Mall for the dates on which the procession had been fixed, but no express reference to the procession was made, though both parties were aware of the reason for the rooms being taken on those dates and a deposit was paid by the defendant. As the procession did not take place the defendant refused to pay the balance for the rooms, and it was decided in the Court of Appeal by Lords Justices Vaughan Williams, Romer, and Stirling that the plaintiff was not entitled to receive the balance. In the course of his judgment Lord Justice Vaughan Williams said: "I think you have to ascertain, not necessarily from the terms of the contract, but, if required, from necessary inferences drawn from surrounding circumstances recognised by both contracting parties, what is the subject of the contract and then to ask the question whether that substantial contract needs for its foundation the assumption of the existence of a particular state of things. If it does this will limit the operation of the general words, and in such case, if the contract becomes impossible of performance by reason of the non-existence of the state of things assumed by both contracting parties as the foundation of the contract, there will be no breach of the contract thus limited." Also it was decided that "each party must rest in the position in which he is found to be when the event occurs which makes the contract impossible of performance, unless there is something special in the terms of the contract which gives one or other of the parties a different right." On these grounds therefore it must be taken to be correct law that in the event of the birth of a baby at a time other than that arrived at by calculation, then, subject to the following qualifications, the nurse will not be able to recover by action any fees at all unless she is free and able to render the usual services. The qualifications are, first, that if the happening of the birth of the child at a wrong date was the direct result of some serious act of carelessness, wrongful behaviour, or negligence on the part of the patient, or probably also of the patient's husband, the nurse would be able to recover her fees; secondly, she would also be able to recover her fees if she had specially contracted that she was to have her fees unless prevented from attending to the case through some fault of her own. This last appears to be the only way out of a difficulty which certainly does entail hardship on nurses, and the suggestion put forward is that on being engaged for a case the nurse should write a letter to the prospective patient containing a clause on the following lines:—

> I wish to say, also, that as it is impossible to be certain in these cases of freedom from accidents I shall expect, as is usual, to receive my fees (or part of them) if from any cause the baby is born at a different time from that which we expect, and I am thereby prevented from coming to you.

This would protect nurses from losing all their fees in cases of accidents to their patients, miscarriages, or miscalculations of dates, but would not cover acts of negligence on their parts or help them if they choose to take overlapping cases. Their only other remedy is to rely upon their patients' generosity.

that organ a solution of salts of sodium magnesium and calcium; and also to relieve the liver with calomel in small repeated doses.

Previous investigation in prophylaxis.—Ladd and Osgood showed that with ether given in a cone 88½ per cent. of the cases showed acetone; with ether given by the open drop method the figures were 26 per cent. Young and Williams found that with ether in a cone 75 per cent. gave acetone, and that with ether by the drop method 47½ per cent. gave acetone. Beesley recommended giving the patients sodium bicarbonate before operation. Beddard suggested giving glucose prior to operation.

Conclusions.—1. That so far as prophylaxis by drugs glucose has a much greater power in controlling the acetonuria than sodium bicarbonate. 2. That the secondary vomiting is in direct relation to the amount of acetone produced. 3. Anæsthetics should be given by an open method. 4. That in all cases of vomiting lasting over 12 hours the stomach should be washed out with a solution of sodium bicarbonate leaving some fluid in that organ.

A CASE OF ANEURYSM OF THE ANTERIOR CEREBRAL ARTERY.

BY A. SALUSBURY MACNALTY, B.A., M.B., B.CH. OXON.,
RESIDENT MEDICAL OFFICER, HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON, AND LATE HOUSE PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.

THE patient, aged 28 years, was admitted to University College Hospital on May 7th, 1908. He gave the following history, which was supplemented in some of its details by his relatives. On April 27th he was at work when he was suddenly attacked with severe headache. The headache was across the top of the head and soon after its onset the patient vomited. He was given some brandy and was sick again. He thereupon left off work, walked home, and went straight to bed. The time occupied in walking home was about eight minutes. When in bed he vomited again and immediately lost consciousness. He remained insensible for 20 minutes, becoming quite rigid; he had no twitchings and no incontinence of urine or fæces during the attack. While unconscious he vomited once. He was seen by a medical man on the 29th and he continued to vomit several times during the day irrespectively of the occasions following the taking of food. On the 30th he vomited a little after each meal. Subsequently to this he had no further sickness. There was intense headache at the back of the head after the recovery of consciousness; this lasted for three days and then it disappeared. The patient never lost the power of movement in the limbs, but after the seizure he experienced a numb feeling in the arms and the legs. On May 1st he had apparently recovered to such a degree that he went out for a short walk. The effort, however, made him very fatigued and he went back to bed again. For the last week before admission to hospital the patient had been losing sight in the right eye and had been seeing double out of that eye. This dimness of vision gradually passed into complete blindness. He experienced a gradual but increasing weakness in the upper and lower limbs. There was a history of gonorrhœa three months previously but no definite specific history could be elicited.

On admission at 6.30 P.M. the patient was somewhat drowsy and his speech was rather slurring in character. He was quite rational and was able to give a history. The axillary temperature was 98·8° F. and the pulse was 96, irregular in force and rhythm, and of poor tension and small volume; there were no missed beats. Nothing abnormal was detected in the cardiac, respiratory, or abdominal systems. There was some scarring of the penis. The urine, which was of a dark amber colour and had a specific gravity of 1024, gave a thick cloud of albumin but no sugar was deposited. The pupils were equal and they reacted to accommodation. The left pupil reacted to light; the right pupil did not react to direct, but did to indirect, stimulation. The patient was blind in the right eye. Visual perception was normal in the left eye. There was no nystagmus. With regard to the cranial nerves there was slight weakness of the masseter on the left side. Both external recti were paralysed, the left more than the right. There were marked ptosis of both eyelids, weakness of the left orbicularis palpebrarum, and obvious facial weakness on the left side. Hearing appeared to be diminished on both sides. The other cranial nerves were normal. Ophthalmoscopic examination revealed marked optic neuritis in the left eye with hæmorrhages in the disc. The right fundus was normal. The motor power was weak in the arms and the legs. There was no anæsthesia, analgesia, or atopognosis. The patient was unable to touch accurately the tip of the nose with his forefinger and could not feed himself. The superficial reflexes were normal, as were also the deep reflexes of the arm and the wrist-jerks. The knee-jerks were absent, a condition which persisted throughout the illness. No murmur was heard on auscultation of the head. The diagnosis was that of cerebral aneurysm. The patient was kept in bed and was given antispecific treatment. The albumin disappeared from the urine on the third day after admission.

There is nothing of note to record until May 16th, when the patient was found to have atopognosis (being unable to localise accurately the position of things touched) and astereognosis. Both superior oblique muscles of the eyeball appeared to be paralysed. Occasionally the patient showed athetoid movements (tabetic type) in the hands. His other physical signs were unchanged, but his general condition had much improved and he took his food well. On the 18th he appeared to have regained more power in his limbs. On the 20th the end came with dramatic suddenness. When examined at 11 A.M. the patient was quite rational and announced that he was feeling much better. The temperature was 96°, the pulse was 84, and the respirations were 20. At 11.30 A.M. he suddenly called out. On coming to the bedside he was found to be unconscious; his breathing was stertorous and his face was deeply cyanosed. There was some twitching of the left side of the face and of the right upper eyelid. The knee-jerks were unaltered and there was no rigidity of the body or the limbs. The patient had a stool just previously to the attack. Oxygen was administered and five minims of solution of strychnine were given hypodermically. Death ensued within ten minutes from the onset of the seizure. On auscultation the heart was heard to beat feebly for a short time after the cessation of respiration.

At the post-mortem examination, 26 hours after death, the body was found to be well nourished and the heart was normal. The aorta throughout its course contained numerous non-calcareous patches of atheroma, while the coronary vessels displayed patches of thickening. The mesenteric vessels were practically unaffected. The lungs showed superficial collapse at the bases with hypostatic congestion. The kidneys and other abdominal organs were quite normal. The convolutions of the brain were flattened and contained brownish patches of staining, especially in the frontal region. The meninges were not thickened. At the base of the brain there was a blood clot extending from the optic chiasma over the floor of the third ventricle to the pons and medulla and extending between the cerebellum and the cerebrum. There was blood in both lateral ventricles. The hæmorrhage extended downwards along the cord as far as the third cervical root. Irregular patches of cartilaginous thickening were present in the arteries at the base of the brain and the internal carotids were much dilated and thickened. On dissection a thin-walled saccular aneurysm was found in the left anterior cerebral artery occurring in its course just after it had given off the anterior communicating branch. The aneurysm was of about the size of a small cherry; it had exercised so much pressure upon the brain substance that it could be seen bulging into one end of the left lateral ventricle, the small mass of blood clots that it contained showing up through the thin wall of the aneurysmal sac. In this region it had caused a certain amount of disorganisation of the adjacent brain substance and the inner wall of the left ventricle showed much ploughing-up. On the other hand, it had crossed the middle line to exert pressure on the right optic nerve. All round the optic nerves the brain showed a considerable amount of brown staining. The blood from the aneurysm took the path usually pursued by it in aneurysms rupturing at the base of the brain. Instead

Dental Committee thereon does not judge him guilty of infamous or disgraceful conduct in a professional respect.

The next case was one against Mr. Charles Morgan. The complaint against him was referred to the Dental Committee and the committee found that the following facts were established by the evidence:—

The said Charles Morgan is on the Dentists' Register as in practice before July 22nd, 1878, and his address in the Register is 56, Queen-street, Cardiff. The said [illegible] edly advertised in the public press by mean [illegible] statements of an objectionable character, [illegible] containing laudatory commendations of his own skill and methods, and by implication claiming superiority over other practitioners. The said Charles Morgan alleges that his advertisements were inserted in self-defence against certain quack advertisements which he put in evidence. The said Charles Morgan has, since the service of the notice of inquiry, stopped his advertisements, tenders an apology, and undertakes not to offend again.

Mr. MORGAN appeared and was accompanied by Mr. POLEY, his counsel. The complainants, the British Dental Association, were represented by Mr. R. W. Turner, instructed by Messrs. Bowman and Curtis-Hayward, solicitors to the Association.

Mr. POLEY made a statement on behalf of Mr. Morgan. He said that his client had apologised and was willing to give any further apology the Council might desire. Mr. Morgan inserted the advertisements in self-defence against certain quack advertisements. He promised on no account to advertise again.

Mr. TURNER asked that the promise should be accompanied by an undertaking to conduct his practice in a professional manner.

Mr. POLEY: That is what my client desires to do.

Mr. TURNER: If he undertakes that I have nothing more to say.

The PRESIDENT announced the decision of the Council in the following terms: Mr. Morgan, the Council has given careful consideration to the report of the Dental Committee and has deferred the further consideration of your case until May next, when you will require to be present and to offer satisfactory evidence as to your professional conduct in the interval with particular reference to your promise to discontinue the issue of all advertisements.

The Council then considered the report of the Dental Committee on the charge against Alfred Davis Rogers and Lionel Cartwright Davis. The committee found that the following facts were established by the evidence:—

1. The said A. D. Rogers and L. C. Davis are both on the Dentists Register as in practice before July 22nd, 1878, and their address in the Register is 140, Edgware-road, Hyde Park, London, W.

2. The said A. D. Rogers is a brother of the said L. C. Davis, having changed his name for professional purposes.

3. Both the said A. D. Rogers and the said L. C. Davis deny that the said A. D. Rogers was a partner in, or had any connexion with, the firm of Rogers and Davis at the date of the matter complained of, and the complainant has produced no evidence to refute this.

4. The said L. C. Davis admits that he carries on practice as a dentist in the name of Rogers and Davis at 140, Edgware-road, and also at 34, Liverpool-street, and 174, Victoria-street, S.W., and that he is a sole partner in the firm responsible for what is done at these three places in the name of the firm.

5. A certain Mr. Bonham, an unqualified person, at the time of the offence alleged acted as assistant to the said L. C. Davis at the Liverpool-street branch, and on Oct. 23rd last the said Mr. Bonham scaled the teeth of a Mr. Bridge, who called there with Mr. Maitland, and charged and was paid 5*s*. for doing this. It is in evidence that the said Mr. Bonham stated to these two witnesses that he was in the habit of performing dental operations there for Messrs. Rogers and Davis and that he took entire charge of the dental practice carried on there, but no other evidence was given in support of the charge. The said L. C. Davis denied that the said Mr. Bonham performed dental operations and stated that he had instructions not to do so. Mr. Bonham, however, was not called.

[illegible] the committee are unable to find [illegible] the charge of the said L. C. Davis [illegible] the said Mr. Bonham to attend [illegible] n them, and to practise dentistry on his behalf in the name of his firm—are proved to their satisfaction, and as above stated there is no evidence to show that the said A. D. Rogers was at the time in any way connected with the practice.

Mr. Rogers and Mr. Davis attended in person.

Mr. DAVIS said that if he had inadvertently done anything wrong he would not do it in future. Further, the premises had been closed and Mr. Bonham was no longer in his service.

The PRESIDENT said: In this case the Dental Committee were unable to find on the evidence that the facts alleged had been proved and therefore there is no motion. I have, however, to put it to you formally and I think it will be your wish that the facts alleged against these two practitioners at the Dental Committee have not been proved.

The Council assented and it was intimated to Mr. Rogers and Mr. Davis that the allegations against these two practitioners had not been proved.

This finished the consideration of charges.

The Council deliberated on certain matters *in camerâ* and when the public were re-admitted the PRESIDENT announced that the Council had directed the Registrar to restore to the Dentists' Register the names of Samuel Foley and Algernon Frederick Green.

The Council then adjourned.

SATURDAY, NOV. 28TH.

The Council resumed its sittings at 299, Oxford-street, W., Sir DONALD MACALISTER, the President, being in the chair.

Miscellaneous Business.

The PRESIDENT moved, and it was agreed, that the judgment of the High Court in the dentist case should be placed on the minutes.

A communication was conveyed to the Council through the PRESIDENT from the Secretary of State for the Colonies, asking for a memorandum on penal procedure for the information of Colonial Governments. It was agreed that the President, together with the legal advisers, should draw up a statement of the kind desired and forward it to the Earl of Crewe.

The Administration of Anæsthetics.

The Council then considered a resolution adopted by the Executive Committee in regard to the administration of anæsthetics and instruction in that subject.

The PRESIDENT said that the Privy Council had forwarded a copy of the proposed General Anæsthetics Bill with a memorandum explaining it. The Lord President of the Privy Council desired an expression of opinion with regard to the provisions in the Bill, which was not a Government measure. He had sent to the Lord President the following communication:—

Sept. 3rd, 1908.

SIR,—With reference to your communication of August 24th, 1908, I have to say that it will give me pleasure to lay it before the next meeting of the Executive Committee. As this, however, will not take place before November next I should like to point out to the Lords of the Council that Clause 2 of the proposed Bill appears to involve a virtual supersession of the General Medical Council and ultimately of the Privy Council. By Section 3 (2) of the Medical Act of 1886, the qualifying examinations for medical diplomas are to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery and midwifery. It is the duty of the General Council to secure the maintenance of this standard of proficiency. By Section 4, any examining body which fails to maintain it may, on the representation of the General Council, be, by order of the Privy Council, removed from the list of recognised bodies. And lastly, by Section 19, if the General Council fails of its duty the Privy Council may exercise the functions of the General Council and remedy its defects.

Clause 2 of the proposed Bill ignores the whole of this legislation, so far as one particular branch of the efficient practice of medicine, surgery and midwifery is concerned. It legislates directly for examining bodies, "recognised by the General Council" (which term by the way includes bodies in the Colonies, in Italy and in Japan, as well as in the United Kingdom), without reference to the General Council or the Privy Council; and it provides no machinery for ascertaining that the examining bodies fulfil the proposed law, nor any penalty for their breach of it.

As President, I have littl [illegible] think that such legislation [illegible] effective in practice. No su [illegible] obstetrical operation for [illegible] ne antiseptic precautions [illegible] These are all included under the term "efficient practice" used in the Medical Act.

I do not anticipate any difficulty in securing, through the existing machinery, i.e. the "recommendation" of the Council, aided by the pressure of "inspection," and if necessary "report to the Privy Council," that all licensing bodies shall make explicit in their regulations, as it is to all intents in their practice, a requirement that their candidates shall have received efficient instruction in anæsthetics. Without specific legislation *ab extra* they have already done so in respect of such special branches as vaccination, surgical dressing, and the like.

Clause 1 of the proposed Bill appears to me to contain what is essential for the protection of the public in this department of practice. It would indeed be well if it could be extended to all departments of practice by which life or limb is endangered.

I am, Sir, &c.,
DONALD MACALISTER, President.

That answer had been considered by the Executive Committee which had arrived at the following resolution:—

(*a*) That the memorandum and proposed Bill be reported to the General Council with the statement that the Executive Committee approve the terms of the President's reply dated Sept. 3rd, 1908, addressed to the clerk of the Privy Counci [illegible] that the Council should inform the Lord [illegible] approve the principle of first clause of the [illegible] to support the provisions to which objection [illegible] letter. (*b*) That the Registrar be directed to c

The covered milk—Sample D—looked and smelt quite fresh.] The bacteriological condition was as follows:—

Sample.	Number of aerobic organisms capable of growth on gelatin at room temper-ture after 40 hours.	Growth in peptone broth at 37° C. 0·0001 c.c.	Glucose broth at 37° C. 0·0001 c.c.		Lactose broth at 37° C. 0·0001 c.c.		Agar slope at 37° C. 0·0001 c.c.	Litmus whey at 37° C.
			Acid.	Gas.	Acid.	Gas.		Acid.
C (exposed milk).	72,600,000	Growth + scum.	+	No note.	+	+	70 colonies.	+
D (covered milk).	24,640,000	Growth + scum.	+	No note.	++	+	7 colonies.	No note.

These results again prove a marked and rapid deterioration of milk exposed to flies, there being in the course of 24 hours no fewer than approximately 40,000,000 more bacteria per cubic centimetre in the exposed milk, and ten times as many organisms capable of growing on agar at the body temperature (37° C.). In round numbers the exposed milk showed 700,000 bacteria per cubic centimetre capable of growing at 37° C. against only 70,000 bacteria in the case of the milk protected from flies.

A further experiment showed that under anaerobic conditions the exposed milk (C) contained spores which on development in milk produced both gas and clot, while the covered milk (D) showed clot alone but no gas.

Remarks.—The importance of protecting milk from flies is illustrated by these experiments. It can readily be understood that the larger the number of flies the greater would be the pollution. It is not difficult to realise how in a fly-ridden district diarrhœal diseases may be in excess unless care is taken to see that food-supplies (especially milk) are protected from the contaminating attentions of flies.

The experiments were undertaken on the lines of natural conditions obtaining in houses, so as to include the natural factors of symbiosis or antagonism of bacteria already existing in an ordinary milk-supply. A point I wish to make is that the number of putrefactive bacteria in milk is of great importance. The chemical changes produced in milk by, say, *thousands* of putrefactive bacteria may perhaps not be sufficient to cause serions diarrhœa, while the chemical changes produced by *millions* of such bacteria may conceivably be very prejudicial and excite acute diarrhœa.

A word as to treatment.—The facts indicate the wisdom of early expulsion of the bacteria and their toxic products by a large dose of castor oil which should, in my judgment, be followed by small doses—say, ten grains—of sulphate of soda every two hours dissolved in sterilised (boiled) water. No food should be given for six or eight hours, and then only *sterilised whey*, commencing with small quantities, gradually increasing same. The utmost care should be taken that all milk used for artificially fed infants should at all times be scrupulously protected from fly contamination, especially in dealing with an infant suffering from or convalescent from epidemic diarrhœa.

Norwich.

A CASE OF TRAUMATIC EXOPHTHALMOS.

BY DAVID RANKEN, M.B., B.S. LOND. & DURH.,
M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON TO THE SPECIAL DEPARTMENTS, ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

THE patient was brought to the Royal Victoria Infirmary, Newcastle-on-Tyne, on August 13th last, with the following history. He was driving a waggon whilst sitting on the shaft when the horse, which happened to be young and restive, lashed out suddenly with one of its hind legs, striking him in the face and knocking him over. His left eye was immediately dislocated forward beyond the lids, and directly afterwards he lost consciousness. About a quarter of an hour afterwards he came to himself and was sick, but felt no pain. The eye still remained protruding from the orbital cavity. Within the next hour he was brought to the hospital and whilst being examined again vomited.

On admission the patient was quite conscious and was able to answer questions intelligently. His pulse was good. There was epistaxis from both nostrils. On the left cheek there were several gashes, one extending into the ala of the nose, and obviously produced by the horse's hoof. The left eyeball protruded well beyond the lids. There was hyphæmia and the bulbar conjunctiva was torn all round in a neat circle quite close to the corneal margin. The sclera was intensely injected and the lids were swollen but not lacerated. No sight whatever remained in the eye. The left cheek was painful to the touch and one was unable to make out by palpation the normal outline of the left side of the face. Crepitus of the nasal bone and the nasal process of the superior maxilla was present. The patient had great pain and difficulty on attempting to open his mouth. The teeth outline was normal and there was no hæmorrhage either from the mouth or ears. Attempts to replace the eye were desisted from because of the pain they caused.

Under chloroform the eye could be easily replaced in the orbital cavity, but slight pressure on the lids was sufficient to luxate it forwards again. One was able to detect with the finger in the left nostril great comminution of the inner wall of the antrum of Highmore. The outline of the orbital plate of the superior maxilla on the face was lost. It was decided to remove the eye, and the recti muscles were divided in the ordinary way. On exposing the optic nerve it was found to be loose, and after dividing the rest of the structures connecting the eyeball with the orbital cavity one was able to draw out exactly two inches of nerve, still firmly connected with the eyeball, but with the cranial end severed as if with a sharp knife. Very little bleeding ensued. The wounds in the cheek were sutured with horse-hair, a sponge was left over the left eyelids, and the nostrils were loosely packed with gauze wrung out of a perchloride of mercury solution.

Recovery was uninterrupted. There was some serous oozing from the eye and nostrils during the next few days. Ten days later the patient left the hospital. He was seen eight weeks after the operation when he stated that he had been working then for some weeks past. The wounds in his cheek were quite healed, his left orbital cavity presented the appearance as after an ordinary excision, and he could open his mouth quite wide.

Fracture of the anterior fossa of the skull with severance of the optic nerve is not a common accident, but when complicated with complete exophthalmos becomes one of extreme rarity. The average length of the optic nerve is 5 centimetres, or about two inches, and hence it must have been severed in this case just at its origin from the optic chiasma, in all probability when passing through the optic foramen. The fracture of the superior maxilla on that side was an additional complication.

This case was under the care of Mr. J. D. Wardale, ophthalmic surgeon to the hospital, and I am indebted to him for permission to publish these notes.

Newcastle-on-Tyne.

EXTENSION OF A PLEURAL EFFUSION TOWARDS THE SOUND SIDE IN A STILL-BORN CHILD

CORRESPONDING TO GROCCO'S PARAVERTEBRAL TRIANGLE.

BY ROBERT D. KEITH, M.A., M.D. ABERD.,
LECTURER ON PHYSIOLOGY, THE STRAITS MEDICAL SCHOOL, SINGAPORE;
AND
ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG.,
CONSERVATOR OF MUSEUM, ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE subject of this note was a still-born child, probably of Chinese parentage, found in the streets of Singapore and investigated by us with a view of discovering the cause of the anasarcous condition of its tissues. In this we were not successful; the ductus venosus which was found absent in a similar case was here present; the heart also was normally formed; the tissues of the body, especially the kidneys, were extensively invaded with leucocytes.

Our main reason for recording the case is that it supports those who regard Grocco's paravertebral triangle of dulness as due to a direct extension of the pleural fluid or contents from the diseased towards the sound side. A reference to is that the first period is [illegible] while the second is only [illegible] majority of the students [illegible] examination continue the [illegible] good in whole or in part in the later years the time lost in the earlier portion of the curriculum. Thus there arises in all the bodies an overlapping of studies not due to the conditions of the curriculum, but dependent upon failure on the part of individual students.

With regard to the statistics the committee had collected, he said he had been surprised to see that there was not so much encroachment upon the Final Examination by the earlier examinations as at first sight seemed likely, and in a great many bodies there was no encroachment at all. But a close examination of the tables would reveal the fact that the Final Examination had not received its fair proportion of additional months of study. That was the state of matters with which they had to deal. What was the remedy? One proposal was that the whole course should be lengthened, but the committee failed to find any justification for recommending this extreme step. Not one of the licensing bodies appeared to be in favour of lengthening the course and there was no opinion in the profession pointing towards lengthening the course as a whole. The feeling seemed to be that the best men could get through the work in the prescribed time and that no barrier should be put in their way. Another suggestion was that the preliminary sciences should be cut out of the medical curriculum, thereby giving more time for the study of the later work. That question was recently debated by the Council and the decision was that it was not necessary at the present moment to cut the preliminary sciences out of the curriculum. The Education Committee therefore did not bring forward any proposal for excluding from the curriculum the preliminary sciences. The committee recommended the following proposal for the approval of the Council:—

> That the regulations of the licensing bodies should be so framed that not less than 18 months of undivided study, or a period equivalent in time-value thereto, where overlapping study obtains (half value being allowed for periods of overlapping study), should be set aside for the first period of the course, extending to the completion of the examinatio [illegible] and that not less than the equivalent in [illegible], of 27 months of undivided study be set [illegible] he course.

Personally he thought that there was nothing objectionable in overlapping. What was important was to see that adequate time was given to each of the great groups. There was only one solution of the difficulty—that they should suggest that a reasonable limiting period should be set for the study of each group of subjects. As would be seen by the proposal submitted, the committee had divided the course into two periods. The first (18 months) would extend to the completion of the examination in anatomy and physiology and the second period should never fall below an equivalent of 27 months of undivided study. The recommendation of the committee was to set a limit to the earlier studies. The limit of 18 months which was proposed was at first sight a small one. What had been done was to take the limit which was in existence at present amongst the licensing bodies. No doubt in the course of time it might happen that the preliminary sciences would be dropped out of the curriculum and would be put in a period before the actual medical studies. At this moment it stood as part of the regulation of the Council that the preliminary sciences should be counted as part of the medical curriculum. 18 months was a small limit for these subjects and the subjects of anatomy and physiology. Therefore this recommendation would interfere with no body in the present circumstances, but it would prevent any limitation in the amount of time given to the earlier subjects. He did not think that they would have any special difficulty in that, because they were making no alteration. There was another point. He had been asked by a member of the Council to say something on the practical working of the proposal with regard to exemption. There were a number of colonial students who came over and took their degrees after having given a requisite attendance. This proposal would in no way affect the situation. In every case where exemption was granted by the licensing body the student had to show that he had taken a course equivalent to the course of the licensing body. If his proposal was adopted in the future the licensing body would just ask the student the details of his course. If he had done something less he would not be accepted. The Examination Committee had suggested the very least possible interference with the present distribution of the curriculum. They could not possibly have suggested a lesser degree of interference. He thought the Council should take an interest not only in the examination but in the teaching of the medical sciences. It would be an important step if the Council adopted the conclusions of the committee. In conclusion, he moved the adoption of the proposal recommended by the committee for the approval of the Council.

Sir C. NIXON seconded the motion.

Dr. SAUNDBY expressed dislike of any further limitations of the curriculum by any hard-and-fast rules. Supposing a student passed in anatomy at the end of his third year and had on the previous two years been attending hospital how much longer would his course be?

Dr. MACKAY: He has two years more to go.

Dr. SAUNDBY did not think this would cause any harm but the Council must have time to consider the subject. It would better give time for consideration if they were to postpone the matter.

Sir C. NIXON was understood to say that not all the licensing bodies would consent to any arrangement which would prevent a medical student attending the hospital earlier than his third year.

Sir JOHN MOORE, speaking as a clinical teacher, observed that although it might be a counsel of perfection to postpone the attendance at hospitals until the third year, it would be a good thing for the medical profession when such a regulation was made compulsory. The sooner the student was able to master his chemistry, physics, and biology, and so give his undivided attention to sickness and surgery, the better for the medical profession.

Mr. THOMSON did not think the report had gone to the root of the matter. He thought that at present sufficient conditions and restrictions were imposed on the unfortunate medical student.

Sir CHARLES BALL could not quite see what machinery could be introduced by the licensing bodies actually to comply with the recommendations as they were now brought forward. He would give one case as an example. Supposing that a student was rejected in anatomy and physiology at the beginning of his third year or the end of his third year. There was nothing which would prevent that man taking an additional course of anatomy at the beginning of his fourth year. How were they to prevent him taking the final subjects in the fourth year? The only measure the Council could have would be to require him to pass his examinations in anatomy and physiology before proceeding with his final subjects. He thought the resolutions of the Examination Committee as they appeared at present were colourless and ineffective. The Council should not take a vote upon them as being recommendations to the licensing bodies as more time was required for their consideration than could be devoted to them now.

Sir THOMAS MYLES was understood to say that the general tendency of opinion in Dublin was as indicated by Sir John Moore, which was that the medical student would be more fit for clinical instruction if he had two years' preliminary study before proceeding to it. He laid before the Council various considerations as to the relative capacities of different students to obtain a knowledge of subjects. If a system of "watertight compartments" were adopted in the curriculum they would exclude a large number of men from the medical profession. He also thought that further time should be given for the consideration of the subject.

Dr. NORMAN MOORE thought that the idea of the Examination Committee in bringing forward the subject of its recommendation at this stage was not that a decision should be come to at once. Its object, it seemed to him, was to make the result of the committee's work known to the Council and through the Council to the public at large, and thus to encourage preliminary discussion. Everyone must admit that such an end was useful. The only way in which the Council could get on in the maze of medical education was by educating itself to the mysteries of the subject. With regard to the very first part of the curriculum, the Royal College of Physicians, with a view to a very serious effort to induce the student to get instruction before he entered his medical course, had at great expense inspected schools and laboratories and had laid down regulations as to the precise amount of instruction to be given before they gave a certificate. They had undertaken to examine in these subjects at the beginning of the student's career. It took a long time to bring any change into operation. As a clinical teacher in a medical school in about 93 mm. Hg, and that outside was gradually raised until the flow through the artery ceased. The difference between the external and the internal pressure was taken as the measure of arterial resistance. The arteries experimented with were the common carotid, the external iliac, and the brachial. 49 male cases were thus examined, and in 36 of these the brachials were tested. In five of the 36 both brachials were tested, making 41 arteries in all. Of the 36, seven were under 30, eight were under 40, 13 were under 50, seven were under and 12 were over 60 years of age. The results showed that the resistance did not vary with age, that at every age exceptional cases occurred, that the extremes varied greatly and irregularly, and that the two brachials might differ by as much as 10 mm. Hg. The same was found to be true of the carotids and iliacs. Moreover, in 21 carotids the resistance to internal pressure was measured as well as that to external. It might be expected that an artery which dilated easily when its internal pressure was raised could also be easily compressed from outside. It was not so. The two forms of resistance did not vary together. The same was true for the iliacs. No connexion could be made out between the fatal disease and the resistance. The conclusions were that when using the sphygmomanometer they must bear in mind that the resistance of the wall of the brachial artery might vary from 4 mm. to 34 mm. Hg; that the readings of the instrument represented the sum of the blood pressure, together with the resistance of the artery; and that they had as yet no clue which would enable them to analyse this total into its two component parts.—Dr. LEONARD E. HILL related the results of some experiments carried out at the London Hospital Medical College by Mr. Martin Flack and himself on the question under discussion. Their method was to investigate the condition of the arteries in the living person. Some experiments by that method had been done by Mr. Charles Martin and it was found that the amount of pressure required to obliterate the wall of an artery was equal to only a few millimetres of mercury. He (Dr. Hill) also referred to the work of MacWilliam in the same direction recorded in the Transactions of the Royal Society. Dr. Hill then fitted up before the members of the section his laboratory assistant with two armlets connected to two independent manometers and demonstrated the blood pressure by independent readings. He stated that there was high pressure in the veins, very high pressure in the arteries, and an exceedingly low pressure in the capillary system.—Dr. GEORGE OLIVER, in the course of his remarks, admitted that cases did occur sometimes in which differences of from 15 to 20 mm. Hg were observed between the two brachial arteries after the greatest precautions had been taken to avoid disturbing factors.—Sir LAUDER BRUNTON said that it was just possible that rigor mortis in the muscular coats of the arteries might have something to do with the differences observed in the pressure.—Mr. J. P. L. MUMMERY thought that it was dangerous to draw conclusions from arteries removed from the body.—Sir T. CLIFFORD ALLBUTT said that the disease from which a subject died and the time of death might render the experiments fallacious.—Dr. HERRINGHAM in the course of his reply said that what he wanted to do was to take some more of these post-mortem arteries, to relax them with sodium chloride, and then to try again and see if the anomalies recorded took place.

Dr. C. J. MACALISTER and Mr. H. C. ROSS of the Royal Southern Hospital, Liverpool, communicated a paper on an Excitant for the Leucocytes of Healthy Persons in the Blood Plasma of Patients Suffering from Carcinoma. They suggested that carcinoma was due to a change in the blood and evidence was given in favour of this view. Cancer frequently appeared in "tidal" organs such as the breast, uterus, &c., and its frequency after irritation and trauma was noted with the fact that all of these conditions were associated with an increased blood-supply to the parts. Since all persons who received injury or suffered from chronic local irritative conditions did not get cancer, the supposition was advanced that another factor, a metabolic change in the blood, was necessary for its production. Reference was made to the works of Loeb and Moore respecting the effects of altered chemistry upon the growth and reproduction of cells. Heredity in cancer would be well explained by a theory which involved a chemical change in the blood and there was a probability that nervous influences and perhaps some antecedent disease might lead to similar changes. Moore said that the blood of all cancer patients was more alkaline than normal, and symptoms resembling those of an alkaloid-like toxæmia were referred to as occurring in cancer patients. While a recently discovered stimulant for leucocytes was being demonstrated, a discussion arose as to the nature of this artificial stimulant. It was pointed out that, in the presence of an alkali, an alkaloid such as atropine must be added to methylene blue to produce stimulation. The connexion between this fact and the alkaloid-like toxæmia, with increase of alkalinity of the plasma of cancer patients, was striking. It was therefore suggested that there might be in cancer a stimulant in the plasma which might play a part in the causation of the disease. After giving evidence that cancer was not an infective disease, experiments were referred to by which it was ascertained that the plasmata of a series of cancer patients stimulated the leucocytes of healthy persons when mixed in certain proportions. This stimulation appeared to be identical with that caused by the artificial stimulant. A large number of control experiments gave negative results except in two patients who had been taking quinine. Attention was directed to the fact that the constituents of the artificial stimulant were coal-tar derivatives and to the incidence of cancer among coal-tar workers. Reference was made to the work of other observers which showed that asymmetrical mitoses, identical with those seen in cancer, could be produced in some epithelial cells by certain alkaloids and coal-tar derivatives.—After Mr. ROBERT JONES (Liverpool) had given an instance showing the value of the method for the purpose of diagnosis, Mr. ROSS described the details of the methods of the investigation.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Elephantiasis treated by Lymphangioplasty.—Bilharziasis.—The Sigmoid Flexure and Rectum in Post-Dysenteric Cases.

A MEETING of this society was held on Nov. 20th, Sir PATRICK MANSON, the President, being in the chair.

Mr. W. S. HANDLEY showed a case of Elephantiasis of the Left Leg treated by Lymphangioplasty, an account of which will be published in THE LANCET.

Dr. F. M. SANDWITH demonstrated a small exhibit of Bilharziasis preparations, mostly from Egypt. Dr. S. Kartulis of Alexandria had lately sent to him a valuable specimen of kidney, ureters, and bladder, together with a rectum showing well-marked papillomata from another case. Dr. Sandwith drew attention to the fact that the ureters were affected with multiple excrescences throughout their whole length, though it was usually only the lower half of the ureters which showed great bilharzial change. Another bladder, presented to the museum of the London School of Tropical Medicine by Professor A. R. Ferguson (Cairo), showed very advanced disease with great thickening and distortion of the organ, while the condition both clinically and histologically was locally malignant. Another of Professor Ferguson's gifts was a section of liver showing bilharzial cirrhosis; the new formation of connective tissue was practically confined to the neighbourhood of the portal veins, while a large tributary of the hepatic vein was seen unaffected by the change. The cut surface of the liver looked somewhat as if the stems of some white clay pipes had been thrust through it at various angles. There was no prominence of the liver lobules or retraction of the capsule as seen in other forms of cirrhosis of the liver. Microscopically the liver showed an increase of the peri-portal connective tissue of the sub-lobular and larger portal canals, some of the fibres of which were arranged concentrically round the eggs of the parasite. Eggs found in the liver often consisted only of the shell with lateral spine, and no eggs were seen lying free among the hepatic cells, or usually in the larger blood-vessels which traverse the cirrhotic tissue. Under the microscope were placed the eggs of the schistosomum hæmatobium from the bladder, ureter, and lung; the eggs in the lung were shown to illustrate the rarity of eggs being found in this organ. When eggs were found they were few in number and appeared to result from a couple of worms which had accidentally lost their way in trying to reach the bladder or rectum. Under break down the system which the Council was endeavouring to set up.

The report was then adopted.

Public Health Rules.

Mr. THOMSON moved:—

That it be referred to the Public Health Committee to consider the advisability of substituting in Rule I. of the resolutions and rules relating to public health, the words "nine months" in place of the words "twelve months," as at present.

Owing to the conditions laid down in Rule I. he said that a period of not less than 12 months had to elapse between registered qualification and the admission of any candidate to any examination. That added three months to the curriculum of nine months, during which the candidate might be doing nothing. That was a hardship, especially in cases where graduates might wish to proceed with all possible haste to the colonies, but before doing so wished to obtain this special qualification.

Dr. WALKER seconded the motion which was agreed to.

The Report of the Pharmacopœia Committee.

On the motion of Dr. NORMAN MOORE the report of the Pharmacopœia Committee was received. This report, which is signed by Sir Donald MacAlister, the President, states that from May 25th to Nov. 21st, 1908, the number of copies of the British Pharmacopœia (1898) sold by the publishers was 537. The total number of copies sold in the year beginning Nov. 18th, 1907, was 1125. Up to the present time 40,306 copies of the Pharmacopœia and 4447 copies of the Indian and Colonial Addendum have been sold. The stock of the Pharmacopœia now on hand consists of 2724 copies, together with 1887 copies of the Addendum. A third interim report from the Committee of Reference in Pharmacy has been received, containing suggestions for the revision of certain monographs of the Pharmacopœia (1898), with proposals respecting the official tests for lead, and the articles to which these tests should be applied. It is proposed to publish the three reports now presented in order that the Pharmacopœia Committee may have the advantage of noting the criticisms or other comments which may be publicly made upon the suggestions therein contained. A tabular analysis of the suggestions made by the medical licensing bodies of the United Kingdom, for the inclusion or omission of articles in the next Pharmacopœia, has been prepared by the secretary, Dr. N. Tirard. Similar suggestions are now being received from the various British medical authorities outside the United Kingdom. When the whole of the information from these sources is ready for consideration the committee will be in possession of a body of material which will be of great value to it in its task of adapting the new Pharmacopœia to the needs of the Empire at large.

No discussion took place on this report.

Students' Registration Committee.

On the motion of Sir HUGH BEEVOR, the report of the Students' Registration Committee was approved.

Unqualified Practice Prevention Committee.

Dr. LANGLEY BROWNE submitted the report of the Unqualified Practice Prevention Committee. He explained that the committee was appointed to ascertain what legal provisions existed in the colonies and dependencies of the Empire and in foreign countries for the prevention of medical practice by other than legally qualified persons, and to consider what steps should be taken to procure effective legislation for the same purpose in the United Kingdom of Great Britain and Ireland. In the end of 1907 the Registrar, by the direction of the President, forwarded a communication to the Privy Council, asking that the Lord President would be so good as to communicate with the Foreign Secretary, the Secretary of State for India, and the Colonial Secretary, in order that the information desired by the Council should be obtained through the proper channels. The Lord President did so and the information obtained was most voluminous. The information had been digested and tabulated as an appendix to the report. This digest of all laws in force within the British Empire and in foreign countries showed what provisions existed for the prevention of medical practice by other than legally qualified persons. It had been drawn up by the officers of the Council and had given them a large amount of extra work. He did not know what the committee would have done without the aid of the President and the office staff. The President, indeed, with his great knowledge of languages was able to give them invaluable assistance, and indeed he believed that almost every language in which the information was received was known to him. The information now brought together by the committee was very complete and valuable and it contained much information not hitherto published. As members of the Council would see from the report, it contained official information from all countries except the United States. The Registrar had applied to the Embassy of the United States with a request for the same kind of information as to the laws in the several States of the American Union and its Territories, but no answer had yet been received. The digest had therefore been supplemented by a statement drawn up by Dr. Bateman from the Medical Acts of the different Federal States and from the Provincial Acts in the Dominion of Canada. Every member of the committee, continued Dr. Langley Browne, was aware of the injury done to the public by the practice of unqualified persons and companies, which is carried on with immunity in this country. As the report further showed, the committee believed that sufficient protection against such injury was not afforded to the public by the present Medical Acts; that the injury was grave and was increasing; and that a remedy must be found in legislation such as existed in most civilised countries. The committee, however, recognised that, before remedial legislation could be looked for, it was necessary that the public should be made more fully aware of the dangerous abuses which existed under present conditions. To this end it was desirable that full inquiry should be made by the authority of His Majesty's Government and the committee was prepared to assist in the production of evidence should such an inquiry be instituted. The Council would see by the report that the committee recommended that the Government should be asked to appoint a Royal Commission to investigate the subject and he thought that they had a fair chance of getting a commission appointed. In conclusion he moved that the Council should adopt the following motion recommended by the committee and transmit it to the Lord President of the Privy Council:—

That the General Medical Council, [illegible] hat medical and surgical practice should be carried on with impunity by persons holding no recognised qualifications, requests the Government to take steps for the appointment of a Royal Commission to inquire into the evil effects produced by the unrestricted practice of medicine and surgery by unqualified persons.

Dr. LATIMER, in seconding the motion, joined in expressing the gratitude of the Council to the President for his valuable services to the committee. He considered that the time was propitious for applying to the Government for the appointment of a Royal Commission. The nation was, he thought, becoming more and more willing to restrict the practice of unqualified persons in various departments of the healing art. There had been a sympathetic response in such matters as the question of midwives. That the legislature had done something to suppress the unqualified midwife was a very encouraging sign. There had been an appreciation of the necessity of dealing with infantile mortality. In his opinion there had been no falling off in the favour shown to measures of this kind. He believed that they were going to the Government at a very proper time to ask its help, and he thought that they would get a sympathetic response. He commented on the steps taken in the colonies and abroad to check unqualified practice. The tendency had been in this country to regard the title as the sign of qualification, but in some countries the law went much further. In Natal, for example, the law penalised any person who being unqualified exercised the functions of a physician. He feared that the medical profession could not yet hope to get comprehensive measures of that kind carried in this country.

Dr. NORMAN MOORE regarded the report of the committee as most valuable. The only part of it which appeared not perfect was that relating to the United Kingdom, but a little research might be given to this part of the subject.

The motion was agreed to.

The Apothecaries' Society of London.

On the motion of Sir HUGH BEEVOR Mr. Charles Stonham, C.M.G., F.R.C.S. Eng., was appointed assistant examiner in surgery to the Apothecaries' Society of London for a period of two years from June 16th, 1908.

followed by recurrence of unhealthy mucous stools. In all such cases a strictured state of the bowel at the sigmo-rectal pylorus would be found, and to cure it the stricture must be treated; this was accomplished by passing the tube of the sigmoidoscope up to the seat of the lesion and introducing an indiarubber bougie or œsophageal tube through the strictured portion. That must be repeated at first twice weekly for, say, three weeks and subsequently once a fortnight for some two or three months. In the intervals between the passage of the rectal tube warm sea-water injections in quantity from one pint to three pints should be thrown up the bowel once or twice weekly.—Sir HAVELOCK CHARLES observed that the size of the intestine varied greatly in different individuals, and even in healthy persons there was great variation in the resistance that was offered to the passage of instruments.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Malignant Disease of the Uterus.—Fibroid Uterus.—The late Sir Arthur V. Macan.—Ectopia Vesicæ complicating Pregnancy.—Myoma and Pregnancy.—Exhibition of Specimens.

A MEETING of this section was held on Nov. 13th, Mr. E. H. TWEEDY, the President, being in the chair.

The PRESIDENT exhibited specimens from 12 cases of Malignant Disease of the Uterus, eight of which had been operated on by Wertheim's method since the last meeting of the section. The cases were not all that he had done, but they made a sad and suggestive exhibit. He had done as large a total extirpation as possible, but some of the cases were obviously not cases in which Wertheim's operation could be performed. He held that they should operate on every possible case that gave the least hope of immediate recovery, even if the immunity were only for six months.—Dr. R. D. PUREFOY agreed that operation should be attempted where there was reasonable hope of survival. Where recurrence took place it was attended with less distress and with almost absence of discharge.—The PRESIDENT, in reply, said that he had a good many more cases tabulated, but he thought it better to defer a paper for some time in order that he might be able to follow them up and see how much good had been done. He now merely recorded the present cases to show that a serious attempt was being made in the country to grapple with the awful disease of cancer of the uterus.

Dr. PUREFOY exhibited a Fibroid Uterus removed along with Hernial Sac for the relief of recurrent peritonitis. The patient, an unmarried woman, about 40 years of age, was in anything but good health at the time of the operation. She had previously undergone ovariotomy, and the cicatrix had yielded, and the case was complicated with a ventral hernia. She sought relief because she suffered from menorrhagia with recurrent peritonitis. The uterus had a layer of lymph on its anterior surface. The point of interest in the case was what had given rise to the peritonitis. Was it the presence of the hernia and the dragging on it caused by adhesions between it and the uterus?—The PRESIDENT said that ovariotomy a few years ago was usually attended with peritonitis. He believed that the suffering was caused by the wound not uniting.

At the conclusion of the exhibits Sir WILLIAM J. SMYLY proposed the following motion in graceful and sympathetic terms:—

> The Obstetrical Section of the Royal Academy of Medicine in Ireland at their first meeting for the present session desire to place on record their regret at the great loss which this Academy, and especially this section, has sustained by the death of Sir Arthur Macan.

—Dr. PUREFOY, endorsing to the full everything that had fallen from Sir William Smyly, said that Sir Arthur Macan had won for himself a foremost position amongst the authorities and exponents of obstetrics and gynæcology in the United Kingdom by assiduous hard work and thoroughness, and the profession had sustained a severe loss in his death.—The PRESIDENT desired to add his personal sorrow at the loss of Sir Arthur Macan to the Rotunda Hospital. The whole world had gained by the life of Sir Arthur Macan and he hoped that they would all keep abreast of the times to the last as he had done.—This motion was carried in silence, all present standing.

Dr. A. N. HOLMES read a paper on a case of Ectopia Vesicæ complicating Pregnancy. The patient, aged 33 years, was admitted to the Rotunda Hospital six and a half months pregnant, suffering from ectopia vesicæ. The separation of the pelvic bones was very marked, as much as six inches. The external genitalia were represented by poorly formed labia majora which diverged upwards, the nymphæ and clitoris by a small band of skin which traversed the introitus vaginæ, the latter being a narrow transverse slit situated very far forward, thus making the perineum very long. At the seventh month labour set in spontaneously. The head was driven down into the long perineum, which was divided, and the head easily delivered. During the puerperium prolapse occurred, as there was no anterior support. The patient left the hospital well, but the infant was stillborn.—Mr. J. SPENCER SHEILL asked how Dr. Holmes had arrived at the conclusion that the separation of the bones was six inches by the x rays, which were not accurate for measurement of the pelvis, but the PRESIDENT thought that the pelvis could now be measured very accurately by their means.—Dr. HOLMES, in reply, said the measurements made as felt with the measure practically coincided with those obtained by the photograph. There had been only 14 similar cases recorded.

Sir WILLIAM SMYLY read a paper on Myoma and Pregnancy. Having briefly referred to the subject in general he detailed a case in which serious complications during childbirth and the puerperium were caused by a myoma as large as an adult fist growing from the lower segment of the uterus and developed between the layers of the left broad ligament. These complications included tedious labour, malpresentation, version and extraction of a dead fœtus, post-partum hæmorrhage, retention of the lochia, followed by putrefaction and septic fever. The removal of the tumour by an abdominal operation was succeeded by a pregnancy which ended in the birth of a living child after a normal labour.—Dr. G. FITZGIBBON cited a case in which a fibroid occupied the entire fundus. It flattened out over the fœtus until in the later months it was difficult to differentiate the tumour from the uterine contents. The case was watched and allowed to go to full term and the woman was delivered of a living child without difficulty.—Dr. PUREFOY said that the difficulty of diagnosing pregnancy in the first few months in fibroid uterus was a matter of great importance and should be constantly present to their minds when dealing with such cases. Sir William Smyly's paper illustrated the fact that a woman having a fibroid uterus often passed through several years of married life before pregnancy occurred. In some cases the tumour remained stationary in pregnancy. In some it diminished, as in a case where several small fibroids were palpated at the first pregnancy, while in a second and third pregnancy their presence was difficult to recognise. On the other hand, in some cases the tumour grew very rapidly. His own observations bore out Sir William Smyly's statement that in some cases they removed fibroid uterus without suspecting it to be gravid. The presence of one or more fibroids would chiefly give them trouble in the third stage. Some observers in England advised patients to avoid matrimony, as pregnancy was fraught with great risk in the circumstances, but that was not their experience in Ireland.—Dr. HOLMES, Dr. R. J. ROWLETTE, Dr. HENRY JELLETT, and Mr. J. S. ASHE discussed the case, and the PRESIDENT said that so far as he knew this case was the first reported in Dublin of myomectomy with subsequent pregnancy. Myomectomy at full term without the removal of the uterus seemed to him an impossible operation in the majority of cases. The hæmorrhage that followed the enucleation of a myoma in a pregnant uterus would be greater than he would like to face. In young married women they would all operate if they were sure they could remove the tumours by myomectomy, but that was what they were not sure of. He therefore always let a young married woman keep the myoma in the hope that she would become pregnant. He thought their resources were quite adequate to deal with the myomatous condition, no matter where situate. It was not always easy to diagnose pregnancy when it occurred in a myomatous uterus.—Sir WILLIAM SMYLY, in reply, said that the tumour was attached to the lower uterine segment. When he opened the broad

On a vote the amendment was rejected by 17 votes to 3. The motion was then agreed to.

Proposed Additional Member of Council.

Dr. Langley Browne had the following motion on the agenda:—

> That representations be made to the Privy Council that it is expedient to confer on the registered practitioners resident in England and Wales the power of returning an additional member to the General Council.

With the consent of the Council he postponed the motion till next session owing to the shortness of the time available at the present session for its consideration.

Methods of Clinical Teaching.

For the same reason this course was also adopted by Dr. Lindsay Steven who had intended to propose the following motion:—

> That the Education Committee be instructed to obtain information as to the methods of clinical teaching in medicine and surgery in operation at the various medical schools of the United Kingdom, and to report to a future meeting of the Council.

An Application for Registration.

The Council then considered an application for registration by Mr. CHARLES REGINALD EDWARDS, Mem. R. Coll. Surg. Eng., 1884, Lic. R. Coll. Phys. Edin., 1884, a medical practitioner entitled to be registered under the Medical Act (1858), but who neglected to effect such registration until after the "appointed day" (June 30th, 1887) under the Medical Act (1886). The application was duly considered by the English Branch Council on Nov. 25th, 1908, when the following resolution was passed:—

> That the Branch Council recommends to the General Council that Mr. Charles Reginald Edwards be registered.

This was agreed to.

Dr. NORMAN MOORE moved a vote of thanks to the President for his able services in the chair and this having been heartily accorded the business of the session ended.

THE REPORT OF THE INSPECTOR UNDER THE INEBRIATES ACTS FOR THE YEAR 1907.

Dr. R. Welsh Branthwaite, the inspector for England under the Inebriates Acts, in presenting his report for the year 1907, restricts himself to little more than the publication of figures on the ground that as he is a member of the Departmental Committee which was recently appointed to inquire into the working of the Inebriates Acts he must avoid comment upon those matters of policy which may presumably be considered *sub judice*. The institutions which are under his inspection are (1) State inebriate reformatories; (2) certified inebriate reformatories; and (3) inebriate retreats; and it may be well to define the scope of the work done under these three sections, so that the figures quoted may assume their real significance.

1. *State inebriate reformatories* are two in number—one for males at Warwick and one for females at Aylesbury. In these the worst cases are dealt with—those who prove too refractory for further control in certified institutions. They may be regarded as being more of a penal than of a reformatory character. During the year 30 men and 32 women were admitted on transfer from certified reformatories and one man and three women directly from courts.

2. *Certified inebriate reformatories* are 11 in number, one, Abbotswood House, Cinderford, Gloucester, being maintained exclusively for males, while the following eight are for females: Royal Victoria Home, Horfield, near Bristol; Duxhurst, near Reigate; Farmfield, Charlwood, Horley, Surrey; Midland Counties Inebriate Reformatory, near Chesterfield, Derbyshire; Southern Counties Inebriate Reformatory, Lewes, Sussex; North Midlands Inebriate Reformatory, Ackworth, Pontefract; Lancashire Inebriate Reformatory, Langho, Blackburn; Eastern Counties Inebriate Reformatory, East Harling, Norfolk; and at Brentry Inebriate Reformatory, Bristol, and the Yorkshire Inebriate Reformatory, Cattal, near York, both sexes are received. Some of these reformatories are maintained by counties or groups of counties and others are charitable institutions where cases are received on the payment of a small maintenance charge. They are altogether certified for the reception of 165 males and 1021 females. Under Section I. of the Inebriates Act, 1898, drunkards who are convicted on indictment of an offence punishable with imprisonment or penal servitude may at the discretion of the court be committed either to a State or to a certified reformatory. To the certified reformatory also may be committed under Section 2 any person who when drunk has been guilty of certain offences (scheduled in the Act) and who also has been convicted three times in the preceding 12 months of drunkenness. To neither reformatory—i.e., State or certified—may the term of committal exceed three years, and under certain conditions the person may be granted a licence to be at large before the committal period has expired. Of the 493 persons who were sentenced during the year under the Inebriates Acts and who were duly admitted (and this number is markedly in excess of that recorded during previous years) 428 were women. The increase in committals is due to the greater number of women dealt with under Section 2 of the Act—for drunkenness and disorder in the streets. There has been a decrease in the number of male admissions owing to a regrettable lack of accommodation. At Brentry alone 80 men were refused admission. This lack of accommodation is partly due to the fact that during the first few years of the working of the Act magistrates made but little use of it so far as men were concerned, and as a consequence one reformatory where men were received had to be closed.

It is not stated in the report why so many more women than men are committed, but one reason for the disproportionate number of female committals may also be due to the reluctance of magistrates to "put away" for a long time the man who, drunkard though he be, is still not always out of work and who when working is the support of his family. Notwithstanding this general increase in the number of admissions fewer persons have proved sufficiently refractory to necessitate a transfer from certified to State reformatories. The conclusion formed from this is that the reformatory officials are becoming more accustomed to the work and are therefore better able to control their inmates with the ordinary means at their command, while it is found that men are less amenable to strict discipline and loss of liberty than women. Reference has been made to the class of cases received at State reformatories. A large number of these persons are mentally defective, although not certifiable under the present lunacy laws, and Dr. Branthwaite points out that "there is no power to detain the most hopelessly defective person after sentence has expired, notwithstanding the recognised condition, certainty of relapse into drunken and disorderly habits, and possible danger to other persons from sudden passionate violence." The community would benefit if the reformatory authorities were to be given power, under proper safeguards, to detain such cases until in the opinion of the medical officers there would be a reasonable hope that further relapses would be improbable.

3. *Inebriate retreats.*—These are 22 licensed inebriate retreats, eight for males, 12 for females, and two for both males and females. Some of these are more or less self-supporting charitable institutions, others are conducted for profit. In these retreats are received habitual drunkards who place themselves under control voluntarily. Some enter under the Act for a period not exceeding two years, others are admitted by private arrangement with the licensees. The number of persons admitted during the year was 595. Of these, 210 were admitted under the Act; the remainder entered without any attestation before a magistrate. Dr. Branthwaite reports that in 68 instances during the year leave of absence from a retreat was obtained for patients, but that in only eight of these was leave granted for ill-health. The remainder obtained leave on account of domestic complications, business exigencies, and as a reward for good conduct. Under Section 19 of the Habitual Drunkards Act, 1879, leave of absence can only be obtained on account of benefit to health. It is, however, a step in the right direction to widen the scope of this section and to enable licensees to obtain leave of absence for patients by making the statutory application to a magistrate in other and reasonable circumstances.

We have already referred to the fact that the report is largely statistical. There are numerous and most useful tables incorporated in, and attached as indices to, the report. To complete the publication we should be glad to see a table giving results of detention and especially to be informed as to the percentage of good results obtained. It is, however, easy to realise that there are great difficulties in the way of obtaining such information.

ependymal epithelium is described at length. Section III., devoted to the cerebro-spinal axis, opens with an account of the gross anatomy of the spinal cord. This is followed by descriptions of its internal structure and of its microscopic structure and is completed by a chapter on the conducting tracts of the cord and the degenerations resulting from lesions. The medulla and pons, the cerebellum, the mesencephalon, the thalamencephalon, and the cerebral hemispheres are all treated in a similar manner, the gross anatomy being followed by an account of the microscopic structure in each instance. In describing the naked-eye anatomy of the cerebral hemispheres the authors acknowledge their indebtedness to Professor Retzius whose work, "Das Menschenhirn," has been freely consulted in the preparation of the present volume. A very useful and instructive chapter on the cerebral hemispheres of the primates, together with a comparison between the human and anthropoid brains, is included in this portion of the work. The remaining chapters of the book are devoted to the minute structure of the cortex, the membranes and the blood-vessels of the brain and the spinal cord, and cranio-cerebral topography.

The book, printed in clear type on good paper, is profusely illustrated with beautiful drawings which are faithfully reproduced and in many instances the text is further elucidated by the clearest of outline diagrams. We cannot speak too highly of the volume which is undoubtedly the best of its kind published within recent years.

Injuries of Nerves and their Treatment. By JAMES SHERREN, F.R.C.S. Eng., Assistant Surgeon to the London Hospital; Surgeon to the Poplar Hospital for Accidents; late Erasmus Wilson Lecturer, Royal College of Surgeons of England. London: James Nisbet and Co., Limited. 1908. Pp. 310. Price 5*s.* net.

THE surgery of the injuries of nerves is of comparatively recent date; much work has been done, both experimental and surgical, and now it may be said that we possess fairly exact knowledge of the subject. This book does not claim to contain an exhaustive account of the surgery of the injuries of nerves but it omits little that is of any importance. Mr. Sherren prefers to discard the expressions "concussion," "contusion," and "laceration of nerves," which describe rather the method of injury of the nerve than the actual damage to the conducting portion of the nerve. They omit the only really important fact for prognosis and treatment, and this is whether the separation from the central nervous system is complete or incomplete; therefore Mr. Sherren divides injuries of the nerves into those with (*a*) complete and (*b*) incomplete division. Further, each of these classes is divisible into two, in one of which the naked-eye continuity of the nerve is intact, and this he terms physiological, and in the other there is a visible solution of continuity or "anatomical division." A good account is given of "plexus-injuries" and of the injuries of individual nerves. The ways in which nerves are damaged are also described, and the causes may be divided in three classes: first, wounds, accidental or operative; secondly, pressure; and thirdly, traction. These various causes affect the individual nerves with different frequency. For instance, the median and ulnar nerves are most commonly injured by penetrating wounds, the musculo-spiral nerve as the result of pressure, and the brachial plexus as the result of traction. The signs and symptoms of the complete division of a peripheral nerve are discussed, the method of examination is described, and the diagnosis is considered. The diagnosis of injury of nerve is perhaps most difficult from hysterical affections coming on after some form of injury.

The treatment is discussed fully and Mr. Sherren points out the need for great care in the treatment of the case after the operation has been performed. The operation of primary suture of a divided nerve is comparatively modern, though it was performed by Baudens so long ago as 1836, yet it was not a recognised method of treatment until 1864 when Nélaton reintroduced it. The author says emphatically that scissors should not be used to pare the ends of a nerve as bruising results. Sterile catgut he considers to be the best suture and one stitch is sufficient in nearly all cases. Chromicised Cargile membrane is used to surround the junction so as to prevent the ingrowth of fibrous tissue and adhesions to surrounding parts. The membrane resists absorption for five weeks and does not cause irritation. What is to be done if in secondary suture of a nerve it is not possible to bring the ends together? Transplantation of nerve is valuable, especially when the nerve employed is taken from the patient or another human being, and Mr. Sherren considers this the method of election; when auto- or homo-transplantation is not possible then either nerve anastomosis or tubular suture may be employed. As to the length of time before recovery of sensation and motion after secondary suture the author considers that it is too irregular for any definite statement to be made. He does not consider that it bears any relation to the time of the secondary suture unless that has been delayed beyond three years. The remaining chapters of the book deal with the lesions of individual nerves and of groups of nerves.

The book is excellent and contains a very good account of the injuries of nerves and their treatment. It is fully abreast of our present knowledge both in the theoretical and in the practical portions.

Human Personality and its Survival of Bodily Death. By FREDERIC W. H. MYERS. Edited and abridged by his son, LEOPOLD HAMILTON MYERS. London: Longmans, Green, and Co. 1907. Pp. 470. Price 10*s.* 6*d.*

THE original edition of this truly remarkable work, which we reviewed in THE LANCET[1] at the time of its appearance, was published in two volumes at the price of two guineas. The editor states that his father before his death indicated the lines upon which an abridgement could be made, and in producing the present abridged edition he has endeavoured to keep as closely as possible to the original scheme and construction of the book. It is now of a size more convenient for the inquirer into the interesting departments of which it treats and it affords a stimulating and instructive record of the experiments and speculations of a highly original mind working in fields of singular difficulty along paths previously almost unexplored. The fundamental object to which it is devoted is the endeavour to answer that most momentous of questions—as to whether the personality of man involves any element which can survive bodily death. The general conclusion to which Mr. Myers's long study of this problem brought him may best be given in his own words: "'The conscious Self' of each of us, as we call it, the empirical, the supraliminal self, as I should prefer to say, does not comprise the whole of the consciousness or of the faculty within us. There exists a more comprehensive consciousness, a profounder faculty, which for the most part remains potential only so far as regards the life of earth, but from which the consciousness and the faculty of earth-life are mere selections and which reasserts itself in its plenitude after the liberating change of death." He adopted the conception of a "subliminal consciousness" and extended it so as to include all the psychical processes which occur beneath the threshold or beyond the margin of that ordinary play of conscious activity, which we commonly call consciousness and which may for descriptive purposes for the Council to agree to such a measure while asking for a Royal Commission to inquire into the evils of unqualified practice is somewhat inconsistent. This section of the medical profession will find it inexpedient that the General Medical Council should be represented on any nursing council to be created by a new Act of Parliament, and the attitude has a logical reason. Others, and we find among them Dr. LANGLEY BROWNE, Dr. L. S. MCMANUS, and Dr. H. A. LATIMER, the three English Direct Representatives on the Council, believe that the medical profession is greatly in favour of the registration of nurses and that a proper registration of nurses can only be for the good of the public by insuring to the public efficient aid to medical services. We are not ourselves so sure that the latter is the view taken by the medical profession at large; at any rate, we have at different times received many communications of an opposite sense, but we think that none the less the question has reached a stage at which it can hardly be further debated. The recent creation of a Central Midwives Board made it almost certain that a similar scheme for the control of general nursing would come into existence, while the General Medical Council has already passed a resolution recommending the registration of nurses. For ourselves we should have liked to hear this very important question debated at greater length by the General Medical Council, but the Council, as the President reminded the members, cannot very well go against its former resolution, while the only argument that ought to be effective to induce them to do so would be the knowledge that the feeling of the medical profession had changed—and this they learn from the evidence of the Direct Representatives is not the case.

---

◆

The Health of the Royal Navy during 1907.

THE report on the health of the Royal Navy for the year 1907 has been published. It is satisfactory to record that a diminished ratio of sickness is reported, probably due to the greater concentration of the total force in home and Atlantic waters. The Channel Fleet shows the lowest and the Irregular List the highest sick list, the latter perhaps due to the fact that under this heading are included the crews of men-of-war proceeding to foreign stations, many of whom, especially young stokers, succumb temporarily to their first experiences of the heat of the tropics. In comparison with the last five years the China station showed an increase of disease, especially as regards venereal diseases, the entries and invaliding ratios of which indicated marked and unsatisfactory additions. As regards malarial fevers it is of importance to note that "the river gunboats all report favourably on the value of mosquito nets and of the prophylactic value of quinine when used systematically." The Australian station "again shows the highest case ratio" as regards venereal diseases. From the North American and West Indian station there are reported seven cases of yellow fever with three deaths. This is the first time any cases of this disease have been reported since 1904; they all occurred on board H.M.S. *Indefatigable* at Barbadoes. The incubation period varied from one to 12 days. The disease was contracted on shore in every instance, each individual attacked had slept in the same locality, and all had been freely bitten by mosquitoes.

From the Mediterranean station there are returned only 14 cases of Malta fever and the origin of every other case reported was traced to the Mediterranean. The following figures may be quoted as a triumph of scientific medicine: "In comparison with the average ratios for the last five years, the case ratio has fallen from 3·47 per 1000 to 0·26, the final invaliding from 0·13 to 0·04 per 1000, and the death from 0·06 to 0·01." From the East Indian station is returned the largest number of cases of malarial fever, Bombay being the commonest place of origin. The returns from the "Home station" under the heading "Diseases of Other Organs of Special Sense" are noteworthy. There are 291 cases noted, with 72 invalidings and one death. Diseases of the ear were responsible for the great majority of the invaliding cases and for the one fatal case. The report informs the public that a careful investigation had been made into all cases under treatment for ear trouble and that in the vast majority of these no connexion with gun-firing could be traced. It is, however, fairly well established that although actual disability rarely follows even continuous exposure to gun-fire, yet a certain degree of deafness and decrease in acuteness of hearing, especially in a crowd, is very liable to be noticed amongst officers and men who have been exposed to the shock of gun-fire, and this liability becomes greater the more continuous the exposure. "It is," concludes the report, "very necessary, therefore, that all officers and men exposed to gun-fire should as far as is practicable take advantage of one of the methods of ear protection now in use." As a review of the health of the whole fleet the report makes cheerful reading but the condition in one respect is, we consider, very unsatisfactory. Venereal disease is still far too common. The total number of cases recorded in 1907 was 13,522. The total number of days loss of service was 329,936, while the average daily number of men ineffective from these diseases was 903·9. These figures should be sufficient to convince the most sceptical of the grave deterioration of the national health implied and to remind them that the mischief may reach generations yet unborn.

We much regret to see the brevity of the appendix to the report, which consists of the laboratory report of the Royal Naval Hospital, Malta, by Staff-Surgeon H. C. WHITESIDE, R.N., and some "analyses of air in double bottoms of iron ships" by Staff-Surgeon OSWALD REES, R.N. Both these are valuable contributions to exact knowledge but when we remember the immense field of work of the medical officers attached to the Royal Navy and Marines "Per mare, per terram" and their opportunities for observing the types and forms of disease amongst all nations of the earth, plus the effects of geographical position, climate, and epidemic and endemic influences in determining and modifying their characters, there can be obviously no want of material for observation and research. As we recently indicated, we wish to look on the medical officers of the navy and army as a body of highly trained organised observers; dealing to such an extent as they must with the manhood of the nation, from their entry as recruits

Chambers's house and used to try experiments on "the girls" in electro-biology, otherwise hypnotism. These experiments were, however, says Lady Priestley, nothing to those which Simpson used to try with chloroform. Simpson, "with some of the liquid simply poured on a handkerchief would have half a dozen of us lying about in various stages of sleep. Our mother feared nothing." Later in life the Priestleys became very intimate with Pasteur and his wife and they had a considerable share in making his work appreciated in this country.

Among other interesting people with whom Lady Priestley came in contact was Mrs. Loudon, the widow of J. C. Loudon, the botanist and writer on agriculture. He must have been a man of iron will, for Lady Priestley relates how owing to rheumatic ankylosis and a subsequent fracture of the humerus which did not unite he found the affected arm so in the way that he determined to have it amputated. When the day came the arm was amputated (there were no anæsthetics in those days), and after the stump had been dressed "he was about to step downstairs, as a matter of course, to go on with his business." He was only persuaded with great difficulty to go to bed.

Loudon was the hero of the delightful story of the Waterloo Beeches, which as Lady Priestley does not mention it, we will, to quote the immortal Mr. Barlow, "now proceed to narrate." One day when Wellington was sitting in the House of Lords he received a note from Loudon to the following effect:—

> MY LORD DUKE,—It would gratify me extremely if you would permit me to visit Strathfieldsaye at any time convenient to your Grace, and to inspect the "Waterloo Beeches."
>
> Your Grace's faithful servant,
> J. C. LOUDON.

The "Waterloo Beeches," we may add, were those planted just after the battle as a memorial. Wellington read the letter twice over and misread the signature as C. J. London. He then replied as follows:—

> MY DEAR BISHOP OF LONDON,—It will always give me great pleasure to see you at Strathfieldsaye. Pray come there whenever it suits your convenience, whether I am at home or not. My servant will receive orders to show you as many pairs of breeches of mine as you wish; but why you should wish to inspect those that I wore at the battle of Waterloo is quite beyond the comprehension of
>
> Yours most truly,
> WELLINGTON.

When "My Dear Bishop of London" (C. J. Blomfield) received this epistle he was not unnaturally somewhat astonished. He showed it to the Archbishop of Canterbury and the other Bishops, who were as much exercised by it as if it had been an Education Bill. The Bishop of London said that he had not written to the Duke for two years. However, explanations eventually came about and the mystery was cleared up.

We will take our leave of Lady Priestley's book by saying that if anyone is tired of the burning questions of the day he will find relief and mental refreshment in reading this pleasantly told chronicle of an age which has gone for ever.

LIBRARY TABLE.

The Truth and Error of Christian Science. By M. CARTA STURGE. London: John Murray. 1908. Pp. 185. Price 2s. 6d. net.—The general nature of the claims of "Christian Science," more especially in regard to the efficacy of mental healing, is fairly well known, but the reasoning or philosophy on which these claims are based, as set forth in the writings of Mrs. Eddy, is probably less familiar. Miss Sturge, after long, sympathetic, and patient study of the published books on the subject, and after association with some of the genuine followers of the cult, has subjected the statements and views of "Christian Scientists" to a logical analysis and to a temperate and unbiassed criticism. The labour involved must have been considerable, since she has been at special pains to discover the general principles and to express them clearly; whereas the writings of Mrs. Eddy abound in contradictions and are generally lacking in sequence. Miss Sturge points out that those statements of the "Christian Scientists" which are true present no novelty, but are such as are generally taught in Christian doctrines or are affirmed by philosophers. The inconsequential character of Mrs. Eddy's deductions is well illustrated by Miss Sturge in a brief epitome of the chief doctrines of "Christian Science." From the main principle that All is God is reduced the generalisation that All is Mind, and further that mind alone is real. Matter is therefore regarded as non-existent, and the entire material world is the creation of what Mrs. Eddy calls Mortal Mind, whatever that may be, for Miss Sturge is unable to find a coherent definition of it. Since the material world is a delusion our bodies are non-existent and disease is therefore equally a delusion, although, curiously enough, as Miss Sturge points out, there must be a condition of bodily health, since Mrs. Eddy's book, "Science and Health," has for its object to teach us how to maintain it. The subject of "mental healing" is considered at some length and in this connexion the importance of suggestion as a therapeutic agent in appealing to some of the subconscious or subliminal activities of mind is emphasised, although Miss Sturge indicates that she does not mean to imply that "Christian Scientists" may not draw power from some higher or spiritual planes, as they claim to do, but the onus certainly lies with them to establish the proof of this. We can commend this small book as a thoroughly temperate and critical exposure of the glaring inconsistencies and exaggerated claims of this strange modern form of mysticism.

Landmarks and Surface Markings of the Human Body. By LOUIS BATHE RAWLING, M.B., B.C. Cantab., F.R.C.S. Eng., Assistant Surgeon, Demonstrator of Practical and Operative Surgery, late Senior Demonstrator of Anatomy, at St. Bartholomew's Hospital; late Assistant Surgeon to the German Hospital, Dalston; late Hunterian Professor, Royal College of Surgeons of England, &c. Third edition. London: H. K. Lewis. 1908. With 31 illustrations. Pp. 96. Price 5s. net.—The demand for this little book having necessitated the publication of a third edition the author has taken the opportunity of increasing its value by the addition of several illustrations. He has wisely refrained from altering the text which therefore remains the same as in the previous edition. The new illustrations besides being well conceived are beautifully executed and materially assist in elucidating the text. The book as it stands fills a long-felt want and we wish it a continuance of the success which it has so deservedly gained.

A Synopsis of Surgery. By ERNEST W. HEY GROVES, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng., Assistant Surgeon to the Bristol General Hospital; Surgeon to the Cossham Hospital; Senior Demonstrator of Anatomy at the University College, Bristol. Bristol: J. Wright and Sons, Limited. 1908. Pp. 486. Price 7s. 6d. net.—Nearly every student who has read a text-book of surgery feels the need as his examination draws near for some way of revising his knowledge, and for such a one this book should prove useful. It appears to contain all that is necessary in a synopsis and the phraseology is not too condensed. No synopsis should be used in place of a treatise on surgery, for the explanations are necessarily omitted or very brief, but such a book as this may legitimately be employed for revising knowledge. So far as we have examined it, it is accurate, but a few misprints occur, such as "bácillus coli commune." The final chapter on Surface Markings is likely to prove useful.

of Lucca, BRUNUS of Calabria, WILLIAM of Salicet, and his eminent pupil LANFRANC of Milan. The new movement spread to France, its chief centres being established at Montpellier about the beginning of the thirteeenth century and in Paris a little later. Towards the end of the thirteenth century LANFRANC was exiled from Milan; he stayed for a time at Lyons, where he wrote his "Chirurgia Parva," and thence he went to Paris where he was invited by the Faculty of Medicine to give a course of lectures on surgery, and the outcome of these lectures was his "Chirurgia Magna" which was completed in 1296. LANFRANC'S influence was personal and fleeting, though his work was carried on for a few years by HENRY of MONDEVILLE, under whom JOHN of GADDESDEN studied. After GUY DE CHAULIAC, who flourished about 1340, surgery suffered in France a fresh eclipse, this becoming almost total when the ecclesiastical authorities of Paris in 1350 forbade the members of the University to practise surgery which, as a mere handicraft, was despised by the cleric physicians. In England, after JOHN ARDERNE, there was no surgeon of great repute for over 200 years.

Throughout the Middle Ages the whole character of thought was ecclesiastical; nearly all the teaching was in the hands of the monks and there was scarcely any learning outside the monasteries. The care of the sick was one of the duties of the monks and from the eighth to the fourteenth century the practice of medicine fell into the hands of the monastic orders. So eagerly did some of the monks pursue the study and practice of medicine that they neglected their religious duties and the study of theology. They left their monasteries in order to attend lectures on medicine and to seek for patients. To stop the evils and scandals to which these absences eventually gave rise many decrees were promulgated by the several Councils of the Church and by the Pope in the twelfth century forbidding monks to practise medicine outside their monasteries. The higher clergy were forbidden to engage in any part of the art of medicine, but the lower clergy were allowed to practise medicine; no surgical operations, however, were permitted to them. The "regular clergy" did abstain, as a rule, from practising surgery, but they were often present at the operations performed by their assistants, directing what should be done. Universities were founded where medicine was taught and practised, but gradually surgery became divorced from medicine and was abandoned to laymen, a few of whom were fairly educated in surgery for the time. Some of these were probably the scanty representatives of the Græco-Roman schools but the greater number of those who performed surgical operations in those days were barbers. Most of these acquired their knowledge not by attendance at professional lectures but by tradition and practice, as indeed was the case with many medical practitioners in this country less than a century ago.

As the barbers grew in knowledge and skill they gradually secured official recognition. A corporation of barbers existed at Montpellier in 1252. In Paris as early as 1301 they had taken the title of "barber-surgeons" and were recognised by the Masters of Surgery who a few years earlier had formed themselves into a fraternity under the invocation of ST. COSMAS and ST. DAMIAN, the patron saints of surgery. The barbers of London were certainly a company at the beginning of the fourteenth century, for, as we have already mentioned, in 1308 a Master was appointed, and even then we find that there were two classes of the members of the company, the barbers proper and those "exercising the faculty of surgery."

The claims of barbers to practise surgery were everywhere countenanced by the cleric physicians, especially in Paris where the latter maintained a hostile attitude towards the regular surgeons. By the end of the thirteenth century the barbers had so extended their domain that they performed most of the ordinary surgical operations, except those for stone, cataract, and hernia, which were left in the hands of specialists, many of whom were itinerant. Under the patronage and protection of the physicians, the barbers continued to rise in status and importance and soon obtained almost a monopoly of surgical practice; and at Montpellier and at Paris the physicians both arranged for lectures on surgery and anatomy for the barbers. By educating the barbers the physicians enabled them to triumph over the regular surgeons, both in numbers and in the extent of their practice. In 1348 the Chancellor of the University of Oxford incorporated the barber-surgeons of that city and they enjoyed the privileges of the University of Oxford. In 1505 the surgeons and barbers of Edinburgh presented a petition to the magistrates and town council that their society might be recognised as one of the guilds with exclusive privilege of exercising their craft. This event was celebrated three years ago as the fourth centenary of the Royal College of Surgeons of Edinburgh. In 1446 HENRY VI. established a Guild of Barbers in Dublin and in 1572 ELIZABETH granted a charter, confirming a much older one, to the barber-surgeons of Dublin, uniting the barber-surgeons and the surgeons.

In London, as at Montpellier and Paris, there were three classes of medical practitioners—the cleric physicians, the lay surgeons, and the barbers practising surgery. Between the surgeons and the barbers there was for many years a keen rivalry and jealousy, and not seldom displays of ill-feeling. Each tried in turn to obtain supremacy over the other. In 1369 the Fraternity of Surgeons obtained from the mayor and aldermen of London an ordinance investing them with the power of presenting the defaults of unskilful surgeons, but seven years later the barbers complained to the court against unskilled practitioners in surgery and obtained an ordinance that two Masters should be appointed annually to direct and to rule the craft, to inspect instruments, and to see that none should be admitted to the franchise of the City without attestation of their skill by examination. In 1390, however, four Masters of the Surgeons' Guild obtained authority to present defaults among persons practising surgery. But in 1410 the barbers obtained from the Court of Aldermen confirmation of the privileges granted in 1376, with the significant addition that they should be enjoyed "without the scrutiny of any person or persons of any other craft or trade whatsoever." In 1423 the surgeons attempted to unite with the physicians to form a commonalty of physicians and surgeons, but the attempt failed, and in 1424 the surgical privileges of the barbers were confirmed. In 1462 the barbers received a charter of incorporation from EDWARD the FOURTH in the first year of his reign This charter, from which the Royal College of Surgeons discs and meat are contained in a strong metal vessel provided at the foot with a spout through which the juice escapes. We found that as much as 2½ fluid ounces of juice was obtained by submitting to pressure 4½ ounces of lean beef, which is a yield of well over 50 per cent., a result which may be regarded as the maximum possible. All the parts are accessible for cleaning. This handy little apparatus should find a strong appreciation in the hospital and in the sick room, as by its use a very nourishing fluid may be readily and almost instantly obtained directly from raw meat.

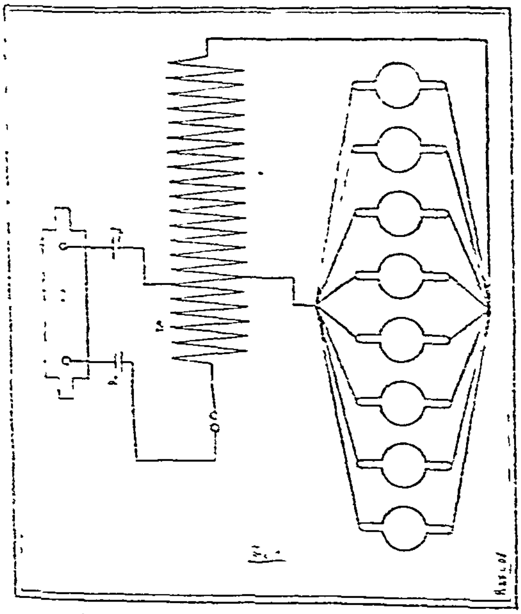
New Inventions.

X RAY TREATMENT OF INTERNAL PROCESSES.

THE different kinds of radiation used to an ever-increasing extent in modern medicine, and most of all Roentgen rays, are known not only to exert a curative effect on morbid tissues but at the same time to affect sound parts in a disadvantageous manner. They require, therefore, in order to avert any harmful secondary effects, the most careful measures of precaution.

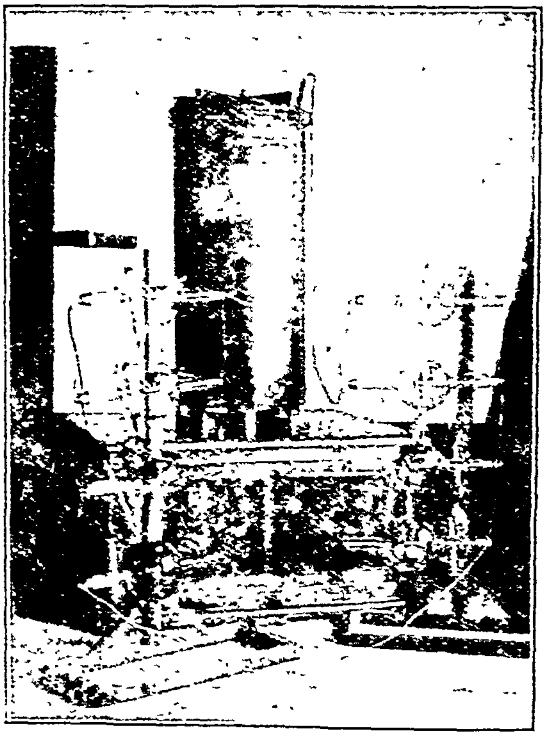
Now, of these two effects, that exerted on the morbid tissues is by far the stronger, and to this fortunate circumstance are due the curative effects insured by x ray radiation. It may be said fairly that in the application of x ray treatment medical men have so far been mainly limited to the surface of the body, there being no means available of generating a radiation of a sufficiently constant penetrative power to reach the deeper parts of the body without any damage to the skin. Owing to fluctuations in electro-tension the x ray bulb in fact gives out cathode rays of different speeds, which in turn produce x rays of a penetrative power differing in proportion, and all "hard" radiations hitherto obtained have been invariably mixed with "soft" (or less penetrating) rays which, being absorbed by the skin, resulted in severe injury to the latter. Now, Dr. G. Holzknecht of Vienna, by ingeniously combining different factors, recently suggested a process of generating a uniformly penetrative Roentgen radiation, by means of which internal processes, such as cancerous tumours or seats of tuberculous affections, would seem to be susceptible of most efficient treatment. This radiation is absorbed by the internal parts of the body at least as strongly as at its surface, and as any morbid parts are acted on far more rapidly and intensely than the sound tissues, the curative effects exerted in the interior of the body are attended by no injury to the skin. The factors utilised by Dr. Holzknecht are: (1) a considerable distance between the x ray bulb and the body; (2) filtration of the radiation; (3) production of specially penetrating rays; and (4) radiation in all directions. It may be truly said that the practical utilisation of the process was at first made difficult by the lengthening of the time of treatment due to each of those factors. Owing to the great distance the intensity of radiation in fact decreases (proportionally to its square, that is, by four times for a double distance); filtration results in part of the radiation being lost by absorption, and "hardness" of radiation is accompanied by another loss of energy, while the distribution over several directions in its turn results in a loss of intensity. The lengthening in the time of treatment was at first so considerable as to require from 50 to 100 hours to cause the same amount of radiation to act on the body as could be applied to the skin by a 15 minutes' treatment. By the use of several bulbs and the simultaneous treatment of several patients a relative shortening of the treatment could, it is true, be obtained. Now, Herr H. Bauer of Berlin, according to a communication to the recent X Ray Congress, has been able to design, on the basis of the principles suggested by Dr. Holzknecht, a really practicable apparatus, by the aid of which the time of treatment is reduced to quite normal limits, thus making the process accessible to a general application.

FIG. 1.



Schema showing arrangement of coil-lamps, &c.

FIG. 2.



General view of apparatus.

The inventor uses a high-tension circuit for the simultaneous operation of several Roentgen bulbs, analogous to those employed in wireless telegraphy. In Fig. 1 J represents an induction coil run without any interrupter by connexion to an alternate current circuit, and which feeds a high-tension circuit made up of the Leyden jars L_1 and L_2, the spark gap, and the self-induction coil S. In connexion with the spark gap the same principle has been made use of as was used in the "fulgurator" constructed by Bauer, decomposing the spark into a large number of small partial sparks, by arranging at short distances apart a considerable number of zinc plates between which small sparks are allowed to pass. This reduces the annoying crackling of the spark to a cocoa itself amounting to less than one-third of the weight of the article; but, Mr. Hehner says, "as one of these mixtures had, however, been sold as a mixture, it complied with the requirements of the law." The county council decided, however, to suggest to the County Councils' Association that it should consider the advisability of urging upon the Government the necessity for an amendment of the law permitting the use of a label barely of the size of a sixpenny-piece used in the sale of loose cocoa. But does such a small label comply with the requirements of the law, as Mr. Hehner says? Clause 8 of the Sale of Food and Drugs Act, 1875, says that the label must be "distinctly and legibly written or printed on ...... to the effect that the same is mixed." It is difficult to see how the notice can be distinct or legible on such a small space. However, good may arise from attention being called to the matter.

HEALTH AND SANITATION IN MAURITIUS.

REPORTING on the Blue Book of Mauritius for the year 1907, Sir J. Graham Bower, K.C.M.G., R.N. (retired), Colonial Secretary, puts the present estimated total population at 383,408, there having been an increase both in the Indian and general population. The public health was much better than in 1906, the death-rate decreasing from 40·0 per 1000 in 1906 to 34·7 in 1907, whilst the birth-rate increased from 33·5 to 37·7. An unsatisfactory feature is to be found in the high infantile mortality, and a very high proportion of stillbirths—8·5 per cent.—has at the same time to be recorded. Mauritius lies close to the edge of the southern tropic, and has the climate which is to be expected in such a latitude. It is also in the direct line of the track of the cyclones of the Southern Indian Ocean. But the climate at the lower levels, though unfavourable to man, is very favourable to vegetation; even a hurricane may prove to be a blessing in disguise, and the heat and rain of the summer months, though they fill the hospitals, push the growth of the sugar cane and thus help also to fill the pockets of the sugar planters. The high levels, though damp owing to the condensation of the trade winds, are not unhealthy; and it is poverty rather than climate which should bear the responsibility of the sickness and mortality amongst the population in the higher levels. There are in the colony 14 hospitals and asylums, including those attached to the jails. The admissions during the year numbered 23,355, an increase of 2984 over the previous year's figures, though the case-mortality—5·34 per cent.—was lower than that of 1906 by 0·51. Malarial fever accounted for 4272 admissions, against 3674 in 1906. Dysentery was answerable for 1286 admissions, as against 794 in the previous year. This higher incidence of dysentery was attributable principally to the prolonged drought which was experienced, notably from July to November, and the consequent great stagnation and pollution of the streams and rivers from which a great proportion of the population derive their water-supply. Influenza gave 1264 admissions, against 1768 in 1906, when the disease prevailed epidemically. 1114 admissions were registered for tuberculosis—an increase of 142. Only one case of pertussis came under notice, the epidemic of that complaint having come to an end in 1906. The number of cases of enteric fever notified in accordance with the Contagious Diseases Ordinance was 145, showing an increase of 64. This increase, however, was more apparent than real, being explained by the greater facility now afforded for the differentiation of the existing fevers by the creation of the bacteriological laboratory. Diphtheria was answerable for 60 notifications, against 33 in the previous year. Here again the increase was probably only apparent and indicated the influence of the bacteriological laboratory in determining the final diagnosis in doubtful cases. An epidemic of measles broke out in August. In spite of early precautionary measures the infection spread rapidly, 347 cases having been notified between August and December. Beri-beri, which is not endemic in the island, broke out simultaneously in three out of the four prisons of the colony in February. The source of the infection was traced to the use of a decorticated unstoved white rice from the East, which had been supplied to the prisons for some time. The epidemic at once subsided after the change of diet—from the rice in question to bread at first and to ordinary Indian rice later—had been prescribed and carried into effect. The yearly incidence of plague since 1898 has been as follows:—1899, 1416 cases, 1117 deaths, or 78·9 per cent.; 1900, 796 cases, 593 deaths, or 74·5; 1901, 1093 cases, 805 deaths, or 73·6; 1902, 506 cases, 386 deaths, or 76·3; 1903, 1395 cases, 1035 deaths, or 74·2; 1904, 568 cases, 449 deaths, or 79·0; 1905, 308 cases, 251 deaths, or 81·5; 1906, 434 cases, 344 deaths, or 79·3; and 1907, 224 cases, 178 deaths, or 79·5. It will probably be of interest to compare the alternations of malaria with those of plague; it will be noticed that both favour alternate years:—Malaria: number of cases, 1899, 4152; 1900, 2848; 1901, 4182; 1902, 3360; 1903, 4788; 1904, 3039; 1905, 5123; 1906, 3674; and 1907, 4272. The campaign against rats was carried on with increased vigour during the year under report, 125,558 of these vermin having been destroyed by the rat-catchers employed by the department. This figure compares very favourably with that for 1906, which was only 105,567. Surra continued throughout the year, though with less virulence. Its existence was detected, however, in the southern part of Black River, which had at first escaped contamination. A bacteriological laboratory was established in temporary buildings at Moka pending the construction of a more permanent home at Réduit. Much good research work has been done, but it is too early yet to speak of definite results. Nevertheless, the work in regard to surra is most hopeful. Good work has been done also by assisting the medical profession in cases of doubtful diagnosis.

ST. BARTHOLOMEW THE GREAT.

A MEETING was held on Nov. 27th in the Great Hall of St. Bartholomew's Hospital to support the effort which is now on foot to preserve the ancient gateway of St. Bartholomew the Great. The gate dates from the thirteenth century and originally gave entrance to the church. It is now mixed up with various secular buildings and the whole mass forms part of a property the trustees of which are desirous of modernising by pulling down the old houses. If this is carried into effect the gate would be left as little more than a dilapidated ruin. A letter was read by Sir Aston Webb, the architect of the church, in which it was stated that the trustees offered to sell the freehold of such houses and land as affected the gateway for £1875, the offer to be open to Jan. 1st, 1909. Some £200 more would be required for putting the premises into a habitable condition. Dr. Norman Moore moved:

> That in the opinion of this meeting it is desirable for the preservation of Smithfield Arch that the property over it and six feet to the side of it be secured, and that this meeting pledges itself to use its best endeavours to raise the sum of £1875 and a further £200 to put the house in a habitable state of repair.

Sir F. D. Dixon-Hartland, M.P., Mr. St. John Hope, and Canon Benham spoke in support of the motion which was unanimously adopted. It was announced that promises of support had been received amounting to £600. It is much to be hoped that the needful £1400 will be forthcoming. The city authorities will we are sure not be backward in preserving one of the few remnants of mediæval London which discs and meat are contained in a strong metal vessel provided at the foot with a spout through which the juice escapes. We found that as much as 2½ fluid ounces of juice was obtained by submitting to pressure 4½ ounces of lean beef, which is a yield of well over 50 per cent., a result which may be regarded as the maximum possible. All the parts are accessible for cleaning. This handy little apparatus should find a strong appreciation in the hospital and in the sick room, as by its use a very nourishing fluid may be readily and almost instantly obtained directly from raw meat.

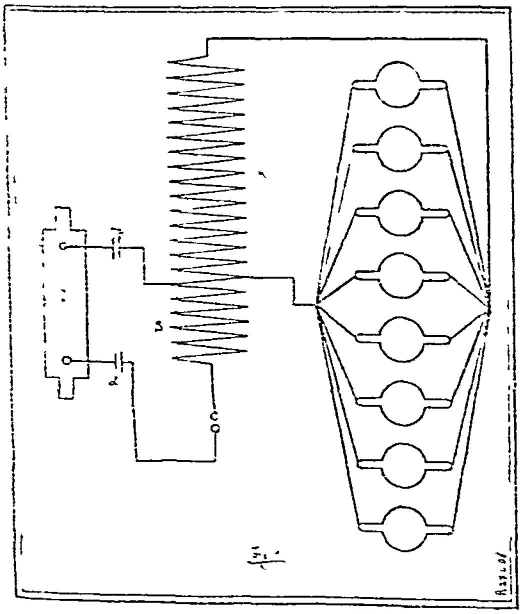
X RAY TREATMENT OF INTERNAL PROCESSES.

THE different kinds of radiation used to an ever-increasing extent in modern medicine, and most of all Roentgen rays, are known not only to exert a curative effect on morbid tissues but at the same time to affect sound parts in a disadvantageous manner. They require, therefore, in order to avert any harmful secondary effects, the most careful measures of precaution.

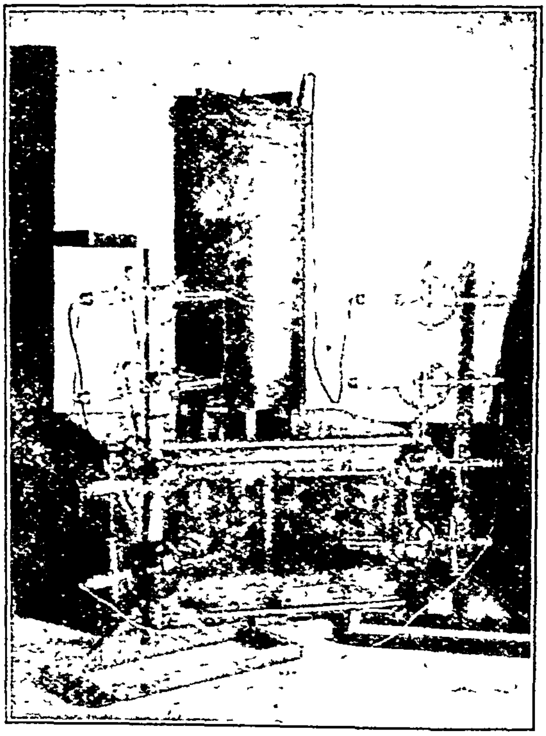
Now, of these two effects, that exerted on the morbid tissues is by far the stronger, and to this fortunate circumstance are due the curative effects insured by x ray radiation. It may be said fairly that in the application of x ray treatment medical men have so far been mainly limited to the surface of the body, there being no means available of generating a radiation of a sufficiently constant penetrative power to reach the deeper parts of the body without any damage to the skin. Owing to fluctuations in electro-tension the x ray bulb in fact gives out cathode rays of different speeds, which in turn produce x rays of a penetrative power differing in proportion, and all "hard" radiations hitherto obtained have been invariably mixed with "soft" (or less penetrating) rays which, being absorbed by the skin, resulted in severe injury to the latter. Now, Dr. G. Holzknecht of Vienna, by ingeniously combining different factors, recently suggested a process of generating a uniformly penetrative Roentgen radiation, by means of which internal processes, such as cancerous tumours or seats of tuberculous affections, would seem to be susceptible of most efficient treatment. This radiation is absorbed by the internal parts of the body at least as strongly as at its surface, and as any morbid parts are acted on far more rapidly and intensely than the sound tissues, the curative effects exerted in the interior of the body are attended by no injury to the skin. The factors utilised by Dr. Holzknecht are: (1) a considerable distance between the x ray bulb and the body; (2) filtration of the radiation; (3) production of specially penetrating rays; and (4) radiation in all directions. It may be truly said that the practical utilisation of the process was at first made difficult by the lengthening of the time of treatment due to each of those factors. Owing to the great distance the intensity of radiation in fact decreases (proportionally to its square, that is, by four times for a double distance); filtration results in part of the radiation being lost by absorption, and "hardness" of radiation is accompanied by another loss of energy, while the distribution over several directions in its turn results in a loss of intensity. The lengthening in the time of treatment was at first so considerable as to require from 50 to 100 hours to cause the same amount of radiation to act on the body as could be applied to the skin by a 15 minutes' treatment. By the use of several bulbs and the simultaneous treatment of several patients a relative shortening of the treatment could, it is true, be obtained. Now, Herr H. Bauer of Berlin, according to a communication to the recent X Ray Congress, has been able to design, on the basis of the principles suggested by Dr. Holzknecht, a really practicable apparatus, by the aid of which the time of treatment is reduced to quite normal limits, thus making the process accessible to a general application.

FIG. 1.



Schema showing arrangement of coil-lamps, &c.

FIG. 2.



General view of apparatus.

The inventor uses a high-tension circuit for the simultaneous operation of several Roentgen bulbs, analogous to those employed in wireless telegraphy. In Fig. 1 J represents an induction coil run without any interrupter by connexion to an alternate current circuit, and which feeds a high-tension circuit made up of the Leyden jars L_1 and L_2, the spark gap, and the self-induction coil S. In connexion with the spark gap the same principle has been made use of as was used in the "fulgurator" constructed by Bauer, decomposing the spark into a large number of small partial sparks, by arranging at short distances apart a considerable number of zinc plates between which small sparks are allowed to pass. This reduces the annoying crackling of the spark to a

Swallowing of solids became difficult. Radioscopy showed an aneurysm of the ascending part of the arch of the aorta of the size of the fœtal head. The aneurysm progressed until it extended three or four centimetres above the right clavicle and inspiration was attended by sub-costal and epigastric retraction. The displacement of the larynx increased; not only was it dragged downwards and backwards by traction of the trachea which was pushed backwards and to the left by the aneurysm but it was directly pushed to the left and backwards by the supraclavicular and suprasternal part of the sac which was in direct relation with the right side of the thyroid and cricoid cartilages. A movement of lateral torsion of the larynx was also produced. The upper part of the larynx projected forwards while the cricoid cartilage and upper part of the trachea, pushed backwards and to the left, lay deep in the neck and were no longer accessible to operation, which, however, the compression of the lower part of the trachea would have rendered useless. The dyspnœa increased and the patient died from asphyxia on July 8th, 1907. The necropsy showed an aneurysm of the size of an infant's head involving the whole of the ascending and transverse portions of the arch of the aorta. It compressed the superior vena cava, the innominate veins, and both pneumogastric and recurrent laryngeal nerves. The trachea was flattened and bent into a curve with concavity to the right. As the lower end of the trachea was fixed beneath the arch of the aorta by the left bronchus the pressure exercised by the aneurysm dragged its upper end with the larynx downwards, backwards, and to the left and at the same time lateral torsion of the larynx to the left was produced. The latter was all the greater as the upper part of the aneurysm pressed the right lateral surface of the larynx to the left and backwards. This condition of lowering, immobilisation, and torsion of the larynx M. Boinet describes as a new sign of aneurysm of the arch of the aorta ("*signe du larynx*"). The regurgitant waves in the right external jugular vein were explained by the obstruction of the superior cava and innominate veins, which distended the jugular veins and rendered their valves insufficient. Compression of both recurrent laryngeal nerves is rare in aortic aneurysm. M. Boinet thinks that the attack of influenza, the only infectious disease revealed by the history, played an important part in the development of the aneurysm.

THE SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

A MEETING of the National Committee for Great Britain and Ireland of the Sixteenth International Congress of Medicine was held at the rooms of the Medical Society of London on Nov. 25th to consider the necessary organisation for Budapest at the Congress of 1909 (August 29th to Sept. 4th). There were present, among others, Dr. F. W. Pavy (in the chair), Sir William S. Church, Sir Dyce Duckworth, Sir Thornley Stoker, Sir Felix Semon, Dr. D. Ferrier, Mr. Walter H. H. Jessop, Dr. F. W. Hewitt, Mr. James Berry, Mr. Hunter F Tod, and the honorary secretaries (Dr. Clive Riviere and Mr. D'Arcy Power). After the minutes of the last meeting had been read and confirmed and letters of apology from absent members had been received, a list of new members of the National Committee for Great Britain and Ireland was read to the meeting. Then the honorary secretaries announced that all the hotel and lodging arrangements at Budapest had been placed by the executive committee of the Congress in the hands of the International Sleeping Car Company. The London offices of the company are situated in Cockspur-street, Charing Cross, and members intending to visit Budapest next year were desired to make early application for rooms to the manager of the London branch. It was also announced that the South Eastern and Chatham and Dover Railway Companies were considering facilities for travelling by through trains to the Congress. The amount of reduction in the fare which would be conceded had not yet been made known but details would be published in due course. A communication from the executive committee at Budapest was then considered in reference to the formation of a permanent international commission to secure the continuity of policy in the international congresses. The general principle was approved and the draft rules were read and discussed. Some amendments were agreed to and it was decided that the Commission should consist of the presidents and general secretaries of the previous and forthcoming congresses and of a delegate from each national committee, the total number of members not to exceed 50. The Commission would appoint its own bureau, the *personnel* of which would be a president, two vice-presidents, a general secretary, and another secretary who, in the opinion of the British National Committee, should be a permanent and paid official residing at some convenient centre in one of the neutral European countries —e.g., at the Hague, Brussels, or Geneva. A letter from the general secretary was then discussed as to the most convenient intervals between the congresses. The National Committee passed a resolution, after a vote had been taken, recommending that the international medical congresses should be held every four years instead of every three years, as had been the custom heretofore. The meeting ended with a vote of thanks to the Medical Society of London for placing its rooms at the disposal of the National Committee.

URBAN AND RURAL INFANTILE DIARRHŒA.

THAT fatal infantile diarrhœa in summer is essentially an urban disease is very generally recognised, but the striking contrast between the summer rates of infant mortality in urban and rural populations, mainly due to difference in the fatality of diarrhœa, is not sufficiently realised. The recently issued quarterly return of the Registrar-General, relating to the three months ending with September last, affords some means for contrasting the recorded infant and diarrhœa mortality in town and country during the past summer. The mean rate of infant mortality during the third quarter of this year was equal to 145 per 1000 births registered in the 76 largest English towns for which the Registrar-General issues weekly returns; and to 130 per 1000 in 142 other smaller towns having populations ranging between 20,000 and 50,000. In England and Wales, exclusive of these 218 large towns, but including all the urban districts with populations under 20,000, the rate of infant mortality did not exceed 102 per 1000. In the six mainly rural counties of Bedford, Bucks, Herts, Suffolk, Wilts, and Dorset, with an aggregate population exceeding a million and a half, the mean rate of infant mortality last quarter was only 63 per 1000, and ranged from 58 in Berkshire to 66 in Buckinghamshire and in Dorsetshire. Even these low rural rates of infant mortality are somewhat overstated, as the Registrar-General's statistics do not afford the means for calculating the rates of infant mortality in the rural sanitary districts within those counties exclusive of the urban sanitary districts. So long, unfortunately, as the Registrar-General's statistics are based upon Poor-law unions, making up what are called registration counties, and not upon sanitary districts and administrative counties, the Registrar-General's statistics will fail to exert their full influence on sanitary authorities. Without the desirable correction for the urban districts in these six rural counties the mean rate of infant mortality therein was very considerably less than half the mean recorded rate in the 218 towns, having an aggregate population exceeding

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, NOV. 24TH (*continued*)

The Reading of the Minutes

A MOTION was agreed to to the effect that the minutes of the Council which had been printed and circulated should be taken as read instead of being read in extenso by the Registrar

Mr. HENRY MORRIS, in commenting on the motion, remarked that in this way the time and the finances of the Council would be economised, as the reading of the minutes usually took about 15 minutes.

The Apothecaries' Hall of Ireland.

The Council then resumed consideration of a motion with respect to the Apothecaries' Hall of Ireland, proposed during its last session by the PRESIDENT. The terms of the motion ran thus:—

> That the examiners appointed by the Council to assist at the qualifying examinations held by the Apothecaries' Hall, Dublin, be instructed to conduct the surgical part of these examinations, and, in addition, to supervise the medical and obstetrical portions with the object of securing that at each qualifying examination the required standard of proficiency is maintained.

When the discussion was broken off six months ago an amendment, moved by SIR THOMAS MYLES and seconded by DR R. SAUNDBY, was under consideration, and it was in the following terms "That the motion be amended by inserting after the words 'held by' the words 'the Society of Apothecaries of London and the.'"

DR F G ADYE-CURRAN (continuing the discussion on the amendment) said that he was in hopes that the Executive Committee might have seen its way after what passed last session to let this matter drop entirely, but he was afraid that he had rather over-estimated its generosity in that respect He held that the duties of the assistant examiners were entirely confined to the examination proper, and when the examination was done their duties were finished also It was incompetent that they should also act as inspectors There was a further inconsistency The assistant examiners were adepts in surgery, but they were called upon to report what sort of examination was conducted by midwifery experts. The treatment to which the Apothecaries' Hall had been subjected had scared away candidates from it. It had damaged its reputation and injured it from the financial point of view He would now ask the Council to let bygones be bygones and to allow the examinations of the Apothecaries' Hall to be conducted in the same way as those of other licensing bodies.

At the suggestion of DR SAUNDBY the amendment was withdrawn at this stage

SIR THOMAS MYLES then moved as an amendment

> That the assistant examiners in surgery appointed by this Council be instructed to report to the Council on the character and conduct of the various qualifying examinations at which they may be present and acting

He said that this amendment would place all bodies to which assistant examiners were sent on the same footing

DR. J LINDSAY STEVEN asked whether this modification of the first amendment was in order

SIR C NIXON said that it might be well to point out that it was only in the case of corporations that were unable to enter into combination that assistant examiners were appointed.

The PRESIDENT ruled the amendment in order.

SIR THOMAS MYLES (continuing his speech) said that the terms of his new amendment took away the sting There was a widespread feeling that the same justice was not meted out to the Irish Apothecaries' Hall as had been meted out in the case of the English institution. Unfortunately, there had been a good deal of hostility to the Apothecaries' Hall. The examinations had been subjected to a course of microscopic examination. His amendment, however, would help the Council to attain to a uniformity of standard throughout the United Kingdom.

DR. L. S. MCMANUS seconded the amendment.

SIR C. NIXON said that he was in sympathy with the amendment to this extent that the same regulations which had been made with regard to the Apothecaries' Hall of Ireland should apply equally to the examinations conducted by the Society of Apothecaries in London At the same time surely the Council should have power to ask its officers who assisted at the examinations to report how they carried out their trust. These examiners were appointed to secure a certain uniformity of standard—a certain proficiency of the way in which the examination was conducted.

SIR HUGH BEEVOR said that it was with the intention of producing a uniformity of standard that the special examinations had been going on in connexion with the Apothecaries' Hall of Ireland In the ordinary course of things they would expect that this result would be attained. Sir Thomas Myles now recommended that they should change their scheme in favour of one of which they had no experience. It did not seem to him logical that because John Smith must be under legal supervision, therefore Tom Smith must also be under legal supervision

MR A THOMSON asked why the Council did not appoint assistant examiners in medicine and midwifery

The PRESIDENT pointed out that the Council could only appoint these assistant examiners when the bodies applied for them

DR NORMAN P WALKER asked whether the inspection of examinations extended to the Apothecaries' Hall of Ireland.

The PRESIDENT replied that inspection had been uniformly applied to the Apothecaries' Hall of Ireland when its turn came, quite irrespectively of supervision.

DR D C MCVAIL said that he could not support the view taken by Sir Thomas Myles Because there was another body in London which had also assistant examiners it did not follow that there should be a like examination

The amendment was lost on a show of hands.

The original motion was carried by 15 votes to 4. Eight members of the Council did not vote.

The PRESIDENT moved further —

> That the examiners be instructed to report fully, for the information of the Council, as to the methods and standards actually adopted at each qualifying examination, and as to the steps they have taken in fulfilment of the duties imposed upon them by section 5 of the Medical Act, 1886

DR. NORMAN MOORE seconded the motion.

DR ADYE-CURRAN moved as an amendment

> That the reports by the assistant examiners in surgery at the Apothecaries' Hall of Ireland be discontinued for the present

He urged that the time had come when the Council might allow the examinations to be conducted in the same way as the examinations of other licensing bodies.

DR MCMANUS seconded the amendment, which was defeated by 18 votes to 6, and the motion was then carried by 21 votes to 3

The Council adjourned

WEDNESDAY, NOV 25TH

The Council resumed its sittings at its offices 299, Oxford-street, W. SIR DONALD MACALISTER, the President, was in the chair

Penal Cases

The Council took up the consideration of penal cases and during the whole of Wednesday, Nov. 25th, and Thursday, Nov 26th, was engaged in hearing charges against a medical man of infamous conduct towards female patients The charges, some of which were old ones, were found not proved and were accordingly dismissed

---

FRIDAY, NOV. 27TH

The Council resumed its sittings at its offices, 299, Oxford-street, W, SIR DONALD MACALISTER, the President, being in the chair.

The Council then took up the consideration (adjourned from May 28th, 1908) of the facts proved against Mr. Arthur Ward The Dental Committee drew up a further report on this case in which the following passage occurred —

> The committee find that Arthur Ward has since the date of the hearing of this case withdrawn the pamphlet complained of and has not since issued, and undertaken in the future not to issue, any pamphlet or advertisement of any kind

The PRESIDENT (after the Council had briefly deliberated *in camera*) announced the decision. He said I have to announce that the Council having further considered the charge proved against Mr. Ward and the reports of the giving the results of the application of diverse methods of resuscitation, cannot be made available for study. The committee also found that its inquiry was greatly handicapped by the fact that post-mortem examinations on the drowned are so imperfectly performed and recorded.

THE PROPOSED EASTBOURNE CENSUS.

THE consent of the Local Government Board to the application of the municipal borough of Eastbourne for a census enumeration of the present population of that borough is full of interest for those who have long advocated the urgent desirability of an intermediate enumeration of the population of this country between the decennial censuses. The borough of Eastbourne had in 1891 an enumerated population of 34,969, which had increased to 43,344 at the last census in 1901. Based upon the rate of increase of population during this intercensal period, the Registrar-General estimates the population of the borough at the middle of this year to be 49,789. The Eastbourne municipal authority appears to be anxious to attain the dignity of a county borough, for which a population of 50,000, as determined by a census, is a necessary condition. Hence the local desire for an immediate census instead of awaiting the next national census in 1911. We believe that the consent of the Local Government Board is conditional upon the census being effected by the local superintendent registrar, the local registrars, and necessary enumerators, under the control of the Registrar-General; the whole of the cost of this exceptional census is, moreover, to be borne by the borough council. We shall watch with interest the result of this local census but the experiment is not entirely free from objection. In the first place it seems doubtful whether the desire of Eastbourne to be created a county borough is an adequate ground for holding an intermediate census almost within two years of the next national census; and the consent to the application of Eastbourne will make it difficult to refuse similar requests from other boroughs with a similar object which could now reasonably await the result of the next census in 1911. There appears, moreover, in view of the strong local desire to prove the claim to a population of 50,000, to be some danger of an attempt to falsify the returns with a view to overstate the population, more especially as in the absence of statutory provision for the enumeration there will be no legal penalty for false returns.

THE PERILS OF BOVINE TUBERCULOSIS.

THE danger to the community from the unsuspected but tuberculous cow, to which we called attention last week, is ably dealt with by Dr. E. C. Schroeder, of the United States Bureau of Animal Industry, in Circular 118, issued by the United States Department of Agriculture. He clearly demonstrates the danger to public health through the consumption of milk or butter from cows which react to the tuberculin test. A series of excellent photographic reproductions is given of dairy cows in apparently splendid condition, all of which were found to be tuberculous. 40 per cent. of these animals were expelling tubercle bacilli in the fæces and consequently were liable to contaminate accidentally the milk during the process of milking as well as the butter prepared from the milk. The prevalence of tuberculosis among dairy cows has been variously estimated at from 10 to 90 per cent., and confirmatory evidence is afforded by the claim made by some dairymen that a milk famine would result from the condemnation of all tuberculous cows for dairy purposes. It is urgently necessary, therefore, that dairy herds should be free from diseased animals. The work of Dr. Albin Burkhardt showed that of 1452 human cadavers 91 per cent. showed tuberculous lesions, irrespectively of the cause of death, and other investigators have placed the figure at 66 to 96 per cent. It would appear that few persons entirely escape the disease, though the majority die from other causes and many are not conscious during life that they are affected. When it is considered that milk has also been shown to contain the germs of enteric fever, diphtheria, scarlet fever, and other diseases, and the poisons that cause the high death-rate from abdominal diseases among young children it does not seem to be possible to exaggerate the need for strenuous action to be taken with the object of securing a permanently pure supply of milk. Dr. Schroeder considers that dairy herds can be rendered free from tuberculosis by the proper application of the tuberculin test and the segregation of all reacting animals.

THE RESEARCH HOSPITAL AT CAMBRIDGE.

AT the latter end of the year 1905 a small hospital of only five beds was opened at Cambridge. It was founded for the study of special diseases and in particular of those diseases which are at present chronic, which disable the patient, for which no cure is at present known, and for which no satisfactory treatment has up to now been found. Cases of such diseases are not for the most part, and rightly so, accepted by ordinary hospitals, simply because so little can be done for them. It was for the study of such diseases that a number of medical men in Cambridge formed a committee and opened the above-mentioned hospital. The first disease to be studied was "rheumatoid arthritis," one which is perhaps less amenable to treatment and more crippling to those whom it attacks than any other. The course of study is as follows: a clinical study of certain new methods of treatment; the bacteriology of certain chronic infections associated with rheumatoid arthritis; a systematic examination of patients in order to discover the seats of such infection; observations on changes in the nervous system associated with rheumatoid arthritis; and a study of the morbid anatomy and histology of cases of rheumatoid arthritis and gout. So far no public appeal has been made for funds, the expenses having been met by the staff, by Cambridge medical students and by various friends, and by the fact that those engaged in the research take no fees and receive no remuneration. The annual expense of keeping the hospital open is £250, and it has been decided to make an appeal for help. The appeal is signed by Sir Clifford Allbutt, Regius professor of physic in the University of Cambridge; Dr. William Osler, Regius professor of medicine in the University of Oxford; and Sir Thomas Barlow, Sir W. Watson Cheyne, Sir William S. Church, Sir Victor Horsley, Sir Jonathan Hutchinson, Sir Donald MacAlister, Professor Howard Marsh, Mr. Henry Morris, and Sir R. Douglas Powell. The work of the committee is fourfold: (1) to give relief to the individual patient; (2) to benefit others suffering from similar diseases by throwing light on their origin and treatment; (3) to discover means of preventing their onset in those at present healthy; and (4) to impart the knowledge thus gained to others. This is a great work and we earnestly hope that the appeal, backed as it is by names of weight, will be successful. The hospital has recently been closed for want of funds. A sum of £8000 would enable it to be kept open permanently. The amount is not large but the benefits would be.

THE Society for the Study of Disease in Children having joined the Royal Society of Medicine as the Section for the Study of Disease in Children, Mr. R. Clement Lucas, the honorary treasurer of the late society, has handed over to the Royal Society of Medicine a cheque for £261 4*s.* 6*d.*, licensing bodies calling their attention to the recommendation of the Council of May 30th, 1907, and inquiring how far they had given effect to this recommendation by requiring students to produce evidence of having received practical instruction in the administration of anæsthetics.

In explanation, said the PRESIDENT, it ought to be said that the first clause of the Bill practically prohibited under a penalty any person who was not a legally qualified medical practitioner administering a general anæsthetic for any surgical or medical operation, act, or procedure, or during childbirth. The Executive Committee desired the Council to approve that principle. The other proposal was contained in Clause 2, which provided that "all examining bodies recognised by the General Council of Medical Education and Registration of the United Kingdom shall require that all candidates before presenting themselves for their final examination shall have received thorough theoretical and practical instruction in anæsthetics, and shall have personally administered anæsthetics under the supervision and to the complete satisfaction of their respective teachers." The objection to that was that it would override the functions of the General Medical Council. Such an enactment had not been found necessary in regard to other branches of medicine, surgery, and midwifery, and as the clause provided no penalty for its infringement it would be practically valueless.

It was then agreed that the first part of the Executive Committee's recommendation should be approved.

The PRESIDENT said that with regard to the second part of the committee's recommendation they felt that the resolution of the General Medical Council transmitted to the licensing bodies within the last year was one to which their special attention should be called in view of the interest taken in the subject in high quarters and of its importance, and that it might serve to emphasise the force of their recommendation if they communicated with all licensing bodies asking what steps they had taken to give effect to it. Accordingly, the committee recommended that the Registrar should be directed to communicate with licensing bodies calling attention to the recommendation of the Council of May 30th, 1907, and asking how far they had given effect to the recommendation by requiring students to produce evidence of having received practical instruction in the administration of anæsthetics.

On the motion of the PRESIDENT this recommendation of the Executive Committee was also adopted.

Advertising by Dentists.

The consideration of a resolution adopted by the Executive Committee in regard to a communication from the British Dental Association was the next business before the Council. This communication inclosed the following resolution passed at the annual general meeting of the association:—

> That in the opinion of this association advertising by certain registered dentists has contributed greatly to the growth of illegal practice by misleading a large proportion of the public, who, for this reason, fail to distinguish between the registered and unregistered practitioner. That the General Medical Council be earnestly requested to take immediate action to suppress as infamous conduct in a professional sense all advertising by registered dentists.

The committee also had before it a communication from Mr. A. H. HIGGS on behalf of himself and other registered dentists objecting to the resolution

> Because it goes far beyond the terms of the resolution of your Council on the same subject passed in 1894, which was decided upon after mature consideration of the statutory conditions regulating the practice of dentistry.

The communication also set forth that

> The Dentists Act itself contains no provisions specifically dealing with advertising, and certainly is far from prohibiting advertising altogether. Advertising was, in fact, practised before 1878 by dentists; at any rate, by the majority of the class who were registered by virtue of their being then in actual practice, so that any alteration in this respect would be an alteration in the conditions under which registered dentists were entitled to remain on the Register after they had once obtained registration. We feel that such an alteration would be unfair.

On this matter the Executive Committee submitted the following resolution:—

> The Executive Committee desire to point out that the General Council have no power to legislate or to issue resolutions binding upon the profession and having absolute prohibitive effect. And in view of their judicial functions in particular cases of professional misconduct, it is not desirable to pass a resolution condemning any practice in general terms until a series of cases decided before them has so clearly demonstrated the prevalence of that practice as to call, in the opinion of the Council, for a warning notice to the profession.

Mr. TOMES thought the existing resolution, the gist of which was that the issue of advertisements of an objectionable character might be carried so far as to constitute infamous and disgraceful conduct in a professional respect, was strong enough for the Council to act upon if necessary. He proposed to move the committee's recommendation in the following modified form:—

> The General Council desire to state that they have no power to legislate or to issue resolutions binding upon the profession and having absolute prohibitive effect, and in view of their judicial functions in particular cases of professional misconduct it is not at present desirable to pass any further resolution.

Sir THOMAS MYLES seconded the proposal.

Dr. SAUNDBY said the resolutions passed by the Council had had a prohibitive effect, and if the Council now declared they had no binding effect and might be disregarded they would do a great deal of harm. He suggested that the resolution should read:—

> The General Council desire to state that in view of their judicial functions in particular cases of professional misconduct it is not at present desirable to pass any further resolution on the subject of advertising by dentists.

Mr. TOMES accepted this form of the resolution and it was then agreed to.

Report of the Education Committee.

Dr. MACKAY, who was indistinctly heard, submitted a report on the curriculum in medicine from the Education Committee. Of recent years, he said, the whole question of the curriculum had been repeatedly raised before the Council and proposals had been remitted to the committee. The argument put forward by those gentlemen whose motion was remitted to the committee was that they were finding the subjects for study for the Final Examination apt to be neglected, particularly by those who had spent too long over the earlier examinations of their course and who had been retarded to such an extent that they had to make good the time lost on the earlier subjects at the expense of the later ones. There should be nothing of that kind. The tendency would be to spoil the work for the Final Examination, for which many would prepare by cramming and not educating themselves. That appeared to constitute a great danger and it was to that that the Education Committee had turned its attention. It was necessary to find out whether men were devoting less time to the Final than they should and whether the Final was being shirked in any way. The committee had collected statistics from all the licensing bodies on the subject. Their report said:—

> An examination of the figures makes it evident that there is wide divergence among the licensing bodies in respect of the periods allotted to the study of the subjects pertaining to the several professional examinations. Each body has what may be called a possible minimum course, which in most cases is clearly expressed in the regulations, and in the others, although not absolutely defined, may readily be deduced from the statistics presented as that followed by the individual students who pass unchecked through the curriculum. To simplify comparison a division of the whole course into two periods has been adopted. The first includes the time spent in the study of the preliminary sciences and of anatomy and physiology and extends to the completion of the examination in these subjects. The second includes all the remainder of the curriculum. In the preparation of the statistics pharmacy has been left out entirely owing to the great diversity of the conditions among the licensing bodies under which it is examined upon. In respect of the main outlines of the curriculum the bodies may be divided generally into three classes, viz.:—
>
> Class 1, in which the first period of the course extends to two years, 21 or 24 months as the case may be. The arrangements in this class probably approach more closely than those of the others to the original intentions of the Council with reference to the subdivision of the curriculum. The class includes the University of Dublin, the University of Durham, the University of Birmingham, and the Conjoint Examining Board in Ireland.
>
> Class 2, in which the first period of the course occupies less than two years, practically 18 months, and in which the second period is correspondingly prolonged. This class includes the Conjoint Examining Board in England and the Conjoint Examining Board in Scotland.
>
> Class 3, in which more than two years are required for the first period. The remaining bodies, the statistics of which have been analysed, belong to this class.

It was evident from a consideration of the facts that in the case of all the bodies included within the third group there was of necessity a certain amount of what might be called normal overlapping study between the subjects of the first and second periods of the course. In every instance three years' hospital attendance was given and in most final subjects such as pathology and surgery claimed a portion of the student's attention in the third year. Dealing with retardation, Dr. Mackay said their report stated:—

> The course may be lengthened as a whole in individual instances, or the first period may be lengthened and the second correspondingly shortened, by failure or delay on the part of the student in passing the examinations. What happens most frequently, as the statistics show,

Motor Union Insurance Company under their special policy also cover certain mechanical breakdowns, and if a chauffeur is employed this risk is worth considering. Fire risks are with careful men very remote, and it is as well to remember that if they are covered it should be for the full value, for if a car worth £300 is only insured against fire for, say, £100 and is absolutely destroyed, the company would only pay £33 6*s*. 6*d*., their proportion of the value.

Servants such as chauffeurs come under the Compensation Act, so if one is employed it is as well to insure against his being injured. Under the Secret Commission Act they are not supposed to make a profit on goods, such as spares, petrol, lubricating oil, which they buy for their employer, so if they should fall down the motor pit or get a back fire they may make up for the "perks" they lose by putting in a big claim under the Employers' Liability and the Workmen's Compensation Acts.

The following are some particulars of first-class companies and I must express my thanks to the various secretaries for the information which I am now able to give, and with these facts any would-be insurer should be able to decide for himself as to which company will answer his requirements the best.

The Commercial Union Assurance Company, Limited, of 24, 25, and 26, Cornhill, London, E.C., issue a special composite policy for cars used either for private or professional use. This policy covers: *public liability*, that is claims by the public for personal injury and damage to property *anywhere* in the United Kingdom up to an *unlimited* amount, and includes law costs incurred with the company's consent; *accidental damage* to the car and lamps, including tyres and accessories when damaged by an accident, which at the same time causes damage to the car itself *anywhere* in the United Kingdom; accidental damage to car sustained during transit by road, rail, *sea*, or inland waterway anywhere in the United Kingdom of Great Britain and Ireland. *Fire and burglary* are included up to the full value of the car *at the time of the fire or loss*. Urgent repairs up to £5 may be executed without waiting for intimation of the company's consent. The following table gives the annual premium for the above-named benefits:—

The h.p. is the lower of the two stated by the maker.	6-h.p.	8-h.p.	10-h.p.	12-h.p.	16-h.p.	20-h.p.
	£ *s.*	£ *s.*	£ *s.*	£ *s.*	£ *s.*	£ *s.*
Full indemnity	8 0	10 0	11 10	12 10	15 10	18 10
If insured bears the first £5 of each claim under each section...	7 0	8 15	10 5	11 5	14 5	17 0
If insured bears the first £10 of each claim under each section...	6 0	7 10	9 0	10 0	13 0	15 10
If insured bears the first £25 of each claim under each section...	4 0	5 0	6 0	7 0	9 10	11 10

For an additional premium of £1, the owner can insure his liability under the Fatal Accidents Act, 1846, the Employers' Liability Act, 1880, the Workmen's Compensation Act, 1906, and at Common Law, in respect of accidents to his chauffeur. Two cars belonging to the same owner (only one being out at a time) can be insured at a reduction of 20 per cent. on the total premiums for both cars. If both cars are out at one time, the reduction will be 10 per cent. For three or more cars special terms will be quoted. The above premiums are reduced by 5 per cent. if assured alone drives.

The Motor Union Insurance Company, Limited, of 1, Albemarle-street, Piccadilly, issue a special policy, which includes the subscription to and full membership of the Motor Union, and motorists who are already members of that body are entitled to deduct the sum of 1 guinea from the premium of the special policy of this company. This policy covers unlimited third-party risks, damage to car, the result of accident, to the full value insured, and repairs up to the value of £5 may be executed upon the authority of the assured, without waiting the sanction of the company, and by arrangement a replacement value of the car can be agreed upon. Special compensation if the repairs take longer than 20 working days, *after acceptance of estimate by the company;* lamps up to a limit of £10 are covered when damaged by an accident and so are tyres. For an extra premium of £5 5*s*. per cent. on the *full value* of the car the breaking or fracturing of any part of the motor, other than by accident or fire, can be covered, but only as far as the actual cost of dismantling and replacing of the broken part, and the owner has to bear the first 50*s*. of each breakdown—for example, the crank breaks, cost of repair and replacement £20, owner pays £2 10*s*. and carriage, the company pays £17 10*s*. The following is the premium chart, excluding charge for mechanical breakdowns:—

—	Value not exceeding—					
	£100	£200	£300	£400	£500	£600
	£	£ s.	£ s.	£ s.	£ s.	£ s.
Not exceeding 8 h.p.	9	10 0	11 0	12 0	—	—
" " 12 "	10	11 0	12 0	13 0	14 0	15 0
" " 16 "	12	13 0	14 0	15 0	16 0	17 0
" " 20 "	14	15 0	16 0	17 0	18 0	19 0

If owner carries first £5 of each claim, above premiums reduced by 15 per cent.; if £10, by 25 per cent.; if £25, by 40 per cent.

The United Legal Indemnity Insurance Society, Limited, of 222–225, Strand, London, whose policies are guaranteed by the Law Guarantee Trust and Accident Society, Limited, of Chancery-lane, a society with a capital of £2,250,000, issue a special policy for medical motorists. This gives unlimited indemnity against claims by the public, whether the result of injury to persons, animals, or property, and includes all law costs incurred with their consent. Accidental damage to the car is covered up to the full value, including lamps up to £5 each and tyres £8 each. Fire is also included up to the full value of the car, and the policy states the actual value of the car, which varies according to the age of the car. The society also pays for certain breakdowns, that is, for the following parts of the car, if fractured, though such fracture is not traceable to an accident, but to a defect: engine crank shaft, crank chamber, flywheel, front axle, rear axle (*but not the driving axle or shaft*), front or rear wheels, and springs. Immediate necessary repairs up to £5 may be executed without consulting the company, and I believe they are well known for the promptness and liberality of their settlement of claims, as well as lack of delay in having repairs executed. The premium varies from £12 10*s*. for a 6-h.p. car to £15 10*s*. for one of 16-h.p. The car may be driven by any competent and licensed person, and if the owner is his own driver they allow a deduction of 5 per cent.

The Ocean Accident and Guarantee Corporation, Limited, of Moorgate-street, London, E.C., issue a policy giving unlimited indemnity as far as claims by the public are concerned, and covering accidental damage to the car, including tyres and lamps up to full value, as well as fire up to full value. On receipt of the name of the maker of the car, date of make, horse power, original cost, and present value of car they will quote the premium chargeable for these risks, as it is their policy practically to make a rate for each and every risk as it comes before them, based upon the conditions under which the car is to be used.

The Car and General Insurance Corporation, Limited, of 1, Queen Victoria-street, London, E.C., issue a variety of benefits, as the following particulars will show:—

Mechanical breakdown.—Damage to car through (*a*) pre-ignition; (*b*) parts becoming slack or breaking adrift; (*c*) breakage of parts; (*d*) overheating; (*e*) freezing; (*f*) presence of any foreign substance; (*g*) defective lubrication; (*h*) chains riding off sprockets; (*i*) tyres, covers, or non-skidding devices coming off; (*j*) using too fierce a clutch, or engaging clutch too suddenly, will be covered anywhere in the United Kingdom up to full value [excluding fire, wear and tear, and depreciation, and the first £10 of each damage].

Accidental damage.—Damage to car by accidental and external means anywhere in the United Kingdom will be covered up to full value at time of damage [excluding fire, wear and tear, and depreciation.]

Tyres, lamps, accessories.—Damage to tyres, lamps, and accessories by accidental and external means whilst actually on insured car [whether car is damaged at same time or not] will be covered anywhere in the United Kingdom up to full value at time of damage [excluding punctures, fire, wear and tear, and depreciation].

Transit.—Damage to car by accidental and external means whilst being conveyed by road, rail, [illegible] United Kingdom, will be covered [illegible] [excluding fire, wear and tear, [illegible] sories].

Claims by the public.—Claims by the public for injury to persons [excluding passengers] or animals or damage to property caused by insured car, anywhere in the United Kingdom, including law costs incurred with the consent of the corporation, will be covered up to an unlimited amount.

London he could remember when there was no restriction on the student's course and when he might at any period of his studies go into the wards and pursue clinical studies while he had not done the first part of his course. The general custom of medical schools was now to prevent a man beginning his clinical studies before he had finished his preliminary studies. Of course, whether it would be wise to have a "watertight compartment" between the preliminary scientific studies and the clinical studies was a subject open to debate. He was certain that nothing whatever was gained by allowing students who had examinations in earlier subjects hanging over them to go on with the Final Examination. Therefore, he strongly approved of giving—and he thought the Council ought to give—every encouragement to the licensing bodies to insist on the period of clinical studies being invaded by no other studies whatever. If it was laid down that the period of clinical study should not be counted until a man had finished his anatomy and physiology, that would lead to an increase in the knowledge of clinical surgery on the part of practitioners when they were admitted to the Register. But the object of the chairman of the Education Committee at present was to bring about a general discussion on the subject.

Dr. NORMAN WALKER said that he had had an opportunity of discussing the subject of the report with three different licensing bodies. In each of these bodies there had been some difficulty in understanding the report. After thorough discussion each of these bodies had come to see that the report was a very reasonable one and the suggestion was one that could be given effect to. The particular proposal that two years and three months should at least be given to clinical work was a thing which would commend itself to every teacher. He thought that it should be made clear that it was clinical instruction that this report particularly dealt with and that the licensing bodies and the universities had in their discretion the regulation of the earlier education. They had in their own control the amount of anatomy and physiology to be taught. All that the members of the Council would like in the interests of the public was that the students should be well instructed in clinical surgery and medicine.

Mr. HODSDON considered that if the medical student knew that he was to have his second period lengthened unless he mastered the preliminary scientific subjects in the allotted time he would work more diligently during his first period. He was not clear with regard to the exemptions of Indian and colonial students.

Dr. LINDSAY STEVEN said that he agreed with the view expressed by Sir John Moore that anything which would permit of the student having his preliminary sciences and his anatomy and physiology over before he actually began hospital work would have a beneficial effect on medical education. With regard to the matters brought before the Council by Dr. Mackay the body which he represented had given careful consideration to the subject and it agreed that no regulation for lengthening the curriculum should be made by the Council. They were more in favour of what was called "the blocking system"—not allowing a student to proceed further until he had passed in his earlier subjects. He had been a clinical teacher for 25 years and from his experience he believed that it interfered with the practical instruction of the student if he was still reading for examinations in anatomy and physiology and it might be with earlier subjects. The body which he represented emphasised the need of devoting the fifth year entirely to clinical work.

The PRESIDENT said the complaint had been made that the earlier subjects were encroaching on the time given to the later subjects, and to verify whether that complaint was well founded required careful analysis of actual facts. That analysis had been made by Dr. Mackay, to whom the whole profession was profoundly indebted for the work he had done. No one could doubt that encroachment on the final stage of the curriculum did take place by reason of the undue extension of the earlier stage. That fact was ascertained for good and they had to face it. The remedy suggested by the Education Committee was that not less than a certain time should be allotted to the subjects in the final stage. He suggested that the issue should be concentrated on the single point of what was the minimum period which by regulations of the bodies should be devoted to the subjects of medicine, surgery, and midwifery. That would be intelligible to the public and the profession.

Mr. MACKAY said that he would be willing to withdraw the proposal and the Education Committee would consider the question again in the light of the debate which they had had that day. The subject caused considerable difference of opinion but he hoped that in time they would all get into one channel. The differences had chiefly been on the questions of overlapping and "watertight compartments." Some had said there should be no overlapping, but, on the other hand, a large number of the bodies at present countenanced overlapping to a large extent, and he thought the Council would find it difficult to put a stop to it. The committee in the interval would endeavour to find a solution of this and the other questions that had been raised.

The matter was then remitted to the Education Committee for further consideration.

The Apothecaries' Hall of Ireland.

The Education Committee submitted the following report:—

The Education Committee had under consideration the following communication:—

"Apothecaries' Hall, Ireland, 40, Mary-street, Dublin,
November 12, 1908.

"H. E. Allen, Esq., LL.B., Registrar, General Medical Council.

"DEAR SIR,—I beg to inclose for the information of the General Medical Council the following resolution which has been passed by my board at its last meeting.

"Yours faithfully,
"HENRY W. MASON, L.R.C.S.I., Secretary.

"Resolved:—'That after the 1st of April, 1909, the usual preliminary examination in general education which was held by this body for so many years be resumed.'"

This is an intimation, the report proceeds, that the authorities of the Apothecaries' Hall, Dublin, intend next year to revive the preliminary examination in arts which, in deference to the express wish of the Council, they have for many years discontinued. The committee are unaware of any circumstances which would justify so serious a reversal of the educational policy which, at the Council's instance, has been generally adopted by the licensing bodies, including the Apothecaries' Hall. The committee, therefore, strongly deprecate the proposed re-establishment of a preliminary examination conducted by a professional body which has no special relation to questions of general education. Should such an examination be notwithstanding instituted for candidates seeking the licence of the Dublin Apothecaries' Hall, it will rest with the Council to decide whether it should be recognised for the purpose of the registration of students in general. Such recognition would affect in a practical way the arrangements of other licensing bodies in regard to preliminary examination.

Accordingly the committee, in view of the grave educational issues involved, recommend that the Council's approval should not be given to the step contemplated by the Apothecaries' Hall, Dublin.

Dr. MACKAY moved the adoption of the report. Exactly the same intimation was received by the Council, he said, in 1903, when a motion was carried in certain definite terms. The committee saw no reason to change its mind and it had replied in the identical words of the resolution of 1903. The policy of the Education Committee had been to try to reduce the number of preliminary examinations and to insure that such examinations were only conducted by bodies which were general educational authorities.

Dr. LINDSAY STEVEN seconded the motion.

Dr. ADYE-CURRAN said that when some years ago the Apothecaries' Hall in deference to the Council ceased to hold preliminary examinations there was a condition that the Colleges of Physicians and Surgeons in Dublin should cease to examine also. That had not been done and for that reason the Apothecaries' Hall were working at a discount. In future the accommodation for students would not be sufficient and that was the reason why the body which he represented was anxious to resume its former examinations.

Sir C. NIXON said that the policy of the Council had been adverse to the conduct of preliminary examinations by bodies that conferred the licences. With regard to the examinations held by the joint Colleges of Physicians and Surgeons in Ireland a strong representation was made by the Education Committee to discontinue the examination. They acquiesced and sent a joint memorial to the Intermediate Education Board in Ireland, asking that body to hold special examinations at suitable times in the year for medical students. The Intermediate Board replied that the expense would be beyond what it could afford and in those exceptional circumstances the Council allowed the preliminary examinations by the joint Colleges to be retained. It would be a complete reversal of the policy of the Council to introduce a second body dealing with professional education to conduct preliminary examinations.

The PRESIDENT said that it would be extremely serious if the Apothecaries' Hall took any action which would tend to the predisposing condition, leucoplakia; and then he said probably he would not have had that leucoplakia if he had not smoked a good deal and if he had not had syphilis. Again, if he had been 25 instead of 45 he probably would not have had cancer. That man might have four brothers who would not show cancer because probably they had not had syphilis and had not smoked excessively. But there was no proof that those brothers were not susceptible to cancer. He had not collected any evidence on the question, but he was led to speak in the discussion because his name was mentioned in Mr. Bashford's paper, and he could not recollect why. Then he found that Dr. Bashford had unearthed a paper which he (Mr. Butlin) read 21 years ago, a report of the collective investigation of the committee of the British Medical Association, a reply to questions addressed to medical practitioners in different parts of the country. Although previously to that he had believed in the constitutional origin of cancer, when he commenced to examine those reports he was very much under the influence of Mr. Cripps's very clever paper. But when he finished with the report he had concluded that there was evidence of a very important kind which had never previously been referred to. The evidence so far did not afford sufficient ground on which to base a theory, but there were many facts which tended in the same direction, and in the absence of evidence to the contrary they must be held for the moment to have a very important place. The point which Dr. Bashford made with regard to the cases in his table concerning hæmophilia and night blindness was that the inheritance did not come down always through the males or always through the females, but sometimes through the male and sometimes through the female. But in Mr. Nettleship's pedigree it came down sometimes through the male and sometimes through the female.

Sir JOHN MCFADYEAN dealt with the question from the facts obtained from breeding and experimentation of cattle, horses, and other animals. With rare exceptions, newly-born calves did not react to tuberculin, and when newly-born non-reacting calves born of tuberculous parents were reared in circumstances which shielded them from infection they remained free from the disease. It had been alleged that tuberculosis was more prevalent in some breeds of cattle than in others—namely, chiefly in shorthorns and Jerseys, and especially also in the Ayrshire breeds. But a study of the question showed that this was not so much so as was generally thought. In forming such conclusions there was the obvious fallacy involved in any attempt to measure the resistance to tuberculosis by comparing the incidence of the disease amongst different groups and individuals without allowing weight to the fact that the disease was contagious, and that the opportunities for infection might have been widely different in the groups compared. The difference in degree of infection could be explained by dissimilarity of environment. Experiments had recently been carried out in which cattle had been infected with measured quantities of tubercle bacilli, and those researches showed that there was no single individual possessing powers of resistance much above or much below the average for animals of the same age and weight. So that in the case of bovines there seemed to be no varying degrees of susceptibility on the part of different breeds of animals. He thought the researches showed that it was not good advice to exhort the medical profession to provide statistical information necessary to establish the comparative incidence of tuberculosis in the descendants of tuberculous and non-tuberculous parents respectively. Such work as that must, he thought, be largely misdirected energy.

Dr. A. M. GOSSAGE desired to deal specially with the question of definite characters and abnormalities being handed down to descendants practically without alteration—i.e., the abnormality was found in the descendants in quite as severe a form as in the parent. That was joined on to another factor—namely, when the abnormal person crossed with a normal person, the result was that some of the children were abnormal and some normal. In order to explain those facts a theory was required, and the only one which covered the cases was that of Mendel. The facts with regard to human beings were not susceptible of confirmation by experiment and the information available was not sufficient to form a theory upon. But Mendel's theory was built up upon facts observed in plant life and lower animals. He proceeded to support the lines of argument already adduced by Professor Bateson of Cambridge in the first day of the debate and gave instances in conditions such as epidermolysis bullosa, diabetes insipidus, &c. With regard to hæmophilia, most of those subjects did not live long enough to beget offspring. Hæmophilia, however, had been found not to be a strictly sex limited disease, and it was not found to come out according to what one would expect according to Mendel's law.

Dr. F. C. SHRUBSALL showed a number of statistics obtained with regard to tuberculosis, chiefly from the records of Brompton Hospital, and viewing the matter from various standpoints. The action of direct heredity did not seem to have any effect in either lengthening or shortening the disease.

Mr. HOWELL T. EVANS showed a number of slides illustrating the perpetuation in successive generations of various abnormalities, such as cephalhæmatoma and cysts in the neck. He also showed photographs of peculiar instances in which an abnormality of the ear in a woman was perpetuated in her daughter, and helical fistula was illustrated in a similar manner. He expressed a strong view in favour of heredity of abnormalities.

Dr. G. A. HERON said that 35 years ago he was a member of the resident medical staff of one of the largest county lunatic asylums in the country, and he had continually noticed in the visitors who were closely related to the patients a low level of intelligence. One of the most striking features of those visitors was stupidity with marked slowness of comprehension. From that low stock had come many inmates of the asylum, and they illustrated various types of insanity, from the actual maniacal and the profoundly melancholic to that most pitiful of human beings, the drivelling idiot. Such observations concerning lunatics and their near relatives were so common that he felt justified in concluding that most of the types of insanity sprang from a stock which was characterised by a low grade of brain development, and that heredity had a no small measure of influence in the incidence of insanity. Whether the low grade brain was an indication of the survival of the unfit or the throwing back of an old time low-grade ancestry he did not know. And he reminded the meeting of the frequent occurrence of religious revivals and an accession of inmates to asylums, and a similar result was noticed in times of great excitement as during the Parliamentary election. When the cause of cancer was known it would be possible to speak with some authority on that subject, but it would be probably admitted that cancer attacked the individual chiefly through the alimentary tract—in other words, that it was an infective disease. The proneness of the body to become the seat of various infections, such as cholera, typhoid fever, small-pox, scarlet fever, relapsing fever, measles, ague, and rabies, was a well-known fact, and he submitted that the same applied to tuberculosis. Before Koch in 1882 demonstrated the true cause of tuberculosis practically every authority on medicine in this country and others believed that the disease was mainly dependent for its existence upon a peculiar hereditary tendency in certain families in consequence of which they fell easy victims to tuberculosis. It was now known that the influence of tuberculosis depended on the infection of the individual and not at all upon any hereditary taint or tendency in the person. And even if it were generally believed that tuberculosis was the expression of an inherited tendency, of what help would that fact be? He thought it probable that a person was to some extent protected from a second attack of tuberculosis by having had one attack, but that knowledge was not of much use in fighting a disease which killed about 50,000 people every year in England and Wales. But great strides were being made in the treatment of the disease, for the death-rate from tuberculosis had now dropped from 35 to 10 per 10,000 of the population.

At the concluding meeting on Dec. 2nd the following were the speakers: Mr. G. P. Mudge (biologist, London Hospital), Professor Karl Pearson, Dr. W. Bulloch, and Mr. N. Bishop Harman. Our account of this meeting will appear next week.

A GLOUCESTERSHIRE CENTENARIAN.—Mr. John Rogers of Tewkesbury celebrated the hundredth anniversary of his birthday on Nov. 20th and was the recipient of congratulations from the King, the Chancellor of the Exchequer, the Lord Mayor of Bristol, and many others.

Tuberculosis Prevention (Ireland) Bill.

The Council then took up consideration of a report of the Irish Branch Council with regard to a point in the Tuberculosis Prevention (Ireland) Bill now under consideration of the House of Commons. The report was in the following terms:—

> The Branch Council desires to bring under the notice of the General Medical Council that it is proposed by Clause 1, Sub-Clause 2, that "the Local Government Board, after consulting with the Irish Branch of the General Council of Medical Education and Registration of the United Kingdom, shall from time to time, by order, prescribe the forms and stages of tuberculosis to which, and the circumstances in which, this section shall apply." The Irish Branch Council, while quite willing to undertake the duty, is of opinion that it would be inequitable that the expenses incurred in discharging this duty should fall on the Irish Branch or on the General Council and desires an expression of the opinion of the General Medical Council on this subject.

Dr. LITTLE moved that the opinion of the Irish Branch Council should be adopted as the opinion of the General Medical Council. The Irish Branch suggested that its views should be brought to the notice of the Government and that the Government should introduce a clause providing for the necessary financial aid.

Dr. NORMAN MOORE asked whether the Royal College of Physicians and the Royal College of Surgeons in Ireland had been consulted in the matter.

Sir JOHN MOORE replied that even the Irish Branch Council had not been consulted.

Sir C. NIXON remarked that the Council should say that it expressed no opinion on the merits of the Bill. It was an extremely cumbrous one and it involved the expenditure of money. It was not likely to get the good results which were intended.

The PRESIDENT thought that it should be made clear that the duty imposed by the Bill on the Irish Branch Council was one involving expense on it and on the General Medical Council and neither was able to bear that expense.

After a short discussion the Council assented to the motion and the PRESIDENT intimated that he would write to the proper quarter expressing the view of the Council on the precise point before it, and expressing no opinion on any other part of the Bill.

Nurses' Registration Bill.

The PRESIDENT said that there was a motion on the notice paper with regard to the Nurses' Registration Bill, but before Sir John Moore moved it he might say a word or two in explanation. The General Medical Council was to have a representative on the council to be set up under the Bill. The rules to be issued by the Nursing Council were not to be submitted to the General Medical Council before they were approved of by the Privy Council as was the case with the rules of the Central Midwives Board. It had been thought by the promoters of the Bill that direct representation would be a more efficient way of proceeding than by submitting the rules to the General Medical Council.

Sir JOHN MOORE then moved:

> That it is expedient that the General Medical Council should stand in the same relation to the proposed General Council for the Registration of Nurses in the United Kingdom as the said General Medical Council does to the Central Midwives Board under Sections 3 and 16 of the Midwives Act, 1902.

He said that whilst this was not a Government Bill when it was introduced into the House of Lords, it was nevertheless adopted by the Earl of Crewe and the Government had given its support to it, even although only indirectly. The Council had had a very important say in the matter of the rules which were promoted by the Central Midwives Board, and these rules had been submitted to the English Branch Council acting for the General Medical Council. He did hold it was most desirable that some influential body like the General Medical Council should have some say in the rules which were to be adopted by the proposed Nursing Council. That council was to frame rules regulating its own procedure and setting out the course of training and other matters. It was most important that the medical profession should see that those rules did not in any way countenance the practice of medicine or surgery by the nurses who went on that Register. The only way to prevent that was to have the rules submitted to a medical body, such as the General Medical Council. The nurses should be placed in the same position as the midwives. He understood that the General Medical Council was to have a representative on the new council proposed by the Bill. It would be quite competent for him to report any rules to the General Medical Council to which he thought exception should be taken and it then could make representations. However, he would rather have the rules submitted to the General Medical Council.

Mr. MORRIS seconded the motion.

Dr. NORMAN MOORE thought that the Bill was a very serious matter. One effect of the Bill might be to establish an inferior but very powerful order of practitioners throughout the country. There were at the present time nurses who were consulted by families instead of a medical practitioner. The Bill, so far as one could judge, would tend in that direction. Therefore its working should be carefully watched.

Mr. MORRIS thought that the procedure adopted under the Midwives Act would be preferable to that now proposed.

Dr. LANGLEY BROWNE said that the medical profession was unanimously in favour of the registration of nurses. The Bill would be as great an advance to the nurses as the Medical Act was to the medical profession.

Sir C. NIXON said that it might be a great advance for nurses but would it be an advance to general practitioners? The proposals in the Bill would seriously interfere with the interests of general practitioners and he could not understand why they supported the Bill. The Bill ought to have been carefully considered by the Council to see what effect it would have on the medical profession.

Dr. LINDSAY STEVEN said the result of his experience was that he was on the whole opposed to the registration of nurses on the lines of the registration of medical men, because the Medical Register was the one which the nurses had always had in view in bringing forward the scheme which was in this Bill. The Council ought to have direct control over the registration of nurses and he would rather that the Council opposed the Bill altogether.

The PRESIDENT said that the Bill had passed the House of Lords and as it had now only to pass the House of Commons it might be law before the Council met again. Did the General Medical Council object to be represented on the Central Board? As the result of an informal vote the majority of the Council seemed to be in favour of the proposal made in the Midwives Act rather than the one in the present Bill.

Dr. McVAIL said that the Bill practically proposed to create an inferior department of the medical profession. A great deal that was done among the poor by medical men would be done by nurses who would soon begin to do medical work and surgery. The General Medical Council ought to look at this matter from the public point of view, and if the Council adopted this motion it would mean that it approved the whole Bill. He was not prepared without further consideration to approve the Bill even with the changes proposed to be made by Sir John Moore. He regarded it as injurious in the interests of the public if there was going to be founded another branch of the medical profession. He did not like this kind of thing being sprung upon the Council in this way.

Sir C. NIXON moved as an amendment that the Council having no opportunity of examining the provisions of the Bill should express no opinion as to whether it was desirable that it should be enacted by Parliament.

The PRESIDENT remarked that the Privy Council knew that the Council had recommended the registration of nurses. He read a resolution on the subject which had been passed. How could it go against its former resolution? It would be better if the members confined themselves to the points given to them for consideration and say that they had had no opportunity of discussing the other points in the Bill.

Sir C. NIXON said that they might be in favour of a certain measure of registration for nurses, but yet not in favour of a Bill which was to create an inferior order of practitioners in medicine. The Council should have an opportunity of discussing the Bill.

The PRESIDENT: That could scarcely be done unless the House of Commons put off the Bill.

Dr. McMANUS said that the vast majority of the practitioners were in favour of the registration of nurses. They wanted to know when they called in a nurse in a poor district that they would get a woman who had been properly trained and properly examined and of whom there was some guarantee about her responsibility and competence. Many a woman now of rather reprehensible character could put on a nurse's hat and cloak and call herself a nurse. If this Bill were passed medical men might be able to prevent this class coming forward.

Dr. LATIMER remarked that a qualified nurse was much more prone to call in a medical man than was the old unqualified woman.

12 in Glasgow, six in Dundee, three in Leith, and two each in Edinburgh and Aberdeen. The 16 fatal cases of whooping-cough corresponded with the number in the previous week; 11 occurred in Glasgow and two in Aberdeen. The nine deaths from scarlet fever showed a further slight increase upon recent weekly numbers and included four in Aberdeen and two in Glasgow. The five fatal cases of diphtheria, of which three were returned in Glasgow, showed a considerable decline from recent weekly numbers. The two deaths referred to "fever" (against seven and five in the two preceding weeks) were both returned in Glasgow; one was certified as enteric and the other as cerebro-spinal meningitis. The deaths referred to diseases of the respiratory organs in the eight towns, which had increased from 56 to 136 in the five preceding weeks, declined again to 133 in the week under notice, and were five below the number returned in these towns in the corresponding week of last year. The causes of 21, or 3·6 per cent., of the deaths registered during the week in the eight towns were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 1·1 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 19·3 and 24·2 per 1000 in the two preceding weeks, declined again to 22·2 in the week ending Nov. 28th. During the first nine weeks of the current quarter the death-rate in the city averaged 19·7 per 1000, whereas the mean rate during the same period did not exceed 14·0 in London and 13·7 in Edinburgh. The 168 deaths of Dublin residents during the week under notice showed a decline of 15 from the high number in the previous week, and included 11 which were referred to the principal epidemic diseases, against eight and 21 in the two preceding weeks. These 11 deaths were equal to an annual rate of 1·8 per 1000; the rate from these diseases in the same week did not exceed 1·3 in London and 0·6 in Edinburgh. Of the 11 deaths from these epidemic diseases in Dublin last week, six resulted from measles, two from diphtheria, two from whooping-cough, and one from scarlet fever, but not one either from "fever," diarrhœa, or small-pox. The six fatal cases of measles showed a decline of two from the number returned in the previous week; and the deaths from whooping-cough also showed a decline. The 168 deaths from all causes during the week included 41 of infants under one year of age and 33 of persons aged upwards of 60 years; the deaths of infants showed a considerable increase, while those of elderly persons had declined. Six inquest cases and six deaths from violence were registered, and 70, or 41·7 per cent., of the deaths occurred in public institutions. The causes of two, or 1·2 per cent., of the deaths in Dublin last week were not certified; the proportion of uncertified causes of death in Edinburgh last week was equal to 5·5 per cent., while in London the causes of all but two of the 1451 registered deaths were duly certified.

THE SERVICES.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel to be Colonel: William Adair Quayle (dated April 1st, 1908).

The King has approved of the retirement of the following officers: Colonel George Jerome Kellie (dated Oct. 15th, 1908); Colonel William George Hume Henderson (dated Nov. 14th, 1908); Lieutenant-Colonel Samuel John Thomson, C.I.E. (dated Jan. 17th, 1908); Lieutenant-Colonel James Barry Gibbons (dated Feb. 17th, 1908); and Lieutenant-Colonel William Henry Wilson Elliot, D.S.O. (dated Nov. 15th, 1908).

TERRITORIAL FORCE.

Yeomanry.

Nottinghamshire (Sherwood Rangers): Surgeon-Captain George Thomson, from the Nottinghamshire (Sherwood Rangers) Imperial Yeomanry, to be Surgeon-Captain, with precedence as in the Imperial Yeomanry (dated April 1st, 1908).

Royal Field Artillery.

1st Northumbrian Brigade: The undermentioned officers, from the 1st Northumberland Royal Garrison Artillery (Volunteers), are appointed to the brigade, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Major John Victor Walton Rutherford, Surgeon-Major (Honorary Captain in the Army) John Wreford, and Surgeon-Captain Robert Anderson Nesham (to be supernumerary).

Royal Engineers.

Headquarters, Welsh Divisional Engineers: Surgeon-Lieutenant James Herbert Dixon, from the 1st Cheshire Royal Engineers (Volunteers), to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Lieutenant James H. Dixon to be Surgeon-Captain (dated May 5th, 1908).

Infantry.

7th Battalion, The Prince of Wales's Own (West Yorkshire Regiment): The undermentioned officers from the 3rd Volunteer Battalion are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain Reginald George Hann and Surgeon-Captain Alexander Mackenzie. 4th Battalion, Alexandra, Princess of Wales's Own (Yorkshire Regiment): Surgeon-Captain Harry L. de Legh to be Surgeon-Major (dated Nov. 11th, 1908). 8th Battalion, The Worcestershire Regiment: Surgeon-Lieutenant Hubert R. R. Fowler to be Surgeon-Captain (dated July 14th, 1908). 5th Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): The undermentioned officers, from the 1st Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Major Edmund Vaudrey, Surgeon-Captain Richard Arnold Johnston (since deceased). 6th Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): The undermentioned officers, from the 2nd Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Lieutenant-Colonel Alfred Chawner and Surgeon-Lieutenant Arthur Wilson Shea. 7th (Robin Hood) Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): The undermentioned officer, from the 1st Nottinghamshire (Robin Hood) Volunteer Rifle Corps, is appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Lieutenant Alexander Tydd Mulhall. 8th Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): The undermentioned officers, from the 4th (Nottinghamshire) Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Captain Frederick William Johnson, Surgeon-Captain Arthur John Helm Montague, and Surgeon-Captain Harry Stallard (to be supernumerary). 5th Battalion, The King's Own (Royal Lancaster Regiment): Surgeon-Captain Bertram W. Hogarth resigns his commission (dated May 20th, 1908). Bertram Whewell Hogarth (late Surgeon-Captain, 5th Battalion) to be Captain (dated May 20th, 1908). 6th Battalion, The Northumberland Fusiliers: Surgeon-Lieutenant William George Richardson, from the 3rd Volunteer Battalion, to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1098). 4th Battalion, The Lincolnshire Regiment: Surgeon-Captain Arthur Stanley Green, from the 1st Volunteer Battalion, to be Surgeon-Captain, with precedence as in the Volunteer Force (to be supernumerary) (dated April 1st, 1908). 5th Battalion, The Lincolnshire Regiment: Surgeon-Captain John Williams Nicholson, from the 1st Volunteer Battalion, to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). The undermentioned officers, from the 3rd Volunteer Battalion, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Francis John Walker and Surgeon-Captain James Matthews Duncan. 3rd Battalion, The Monmouthshire Regiment: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Samuel Butler Mason, from the 4th Volunteer Battalion, The South Wales Borderers, to be Surgeon-Lieutenant-Colonel with honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). 4th Battalion, The Welsh Regiment: Surgeon-Lieutenant William Starbuck Griffith, from the

THE LANCET.

LONDON: SATURDAY, DECEMBER 5, 1908.

The Session of the General Medical Council.

THE Jubilee meeting of the General Medical Council—that is to say, the eighty-eighth session—occurring rather more than 50 years after the foundation of the Council, came to an end on Saturday, Nov. 28th, the members having got through in five days a practical programme and having also touched upon large subjects which will at a later time undoubtedly engage their attention more fully. The economy of time displayed nowadays in the debates of the Council is very praiseworthy. The sessions thereby have become less costly, which means that the pecuniary affairs of the Council are placed upon a much better foundation, while there is also no encouragement given to the making of long speeches which repeat the obvious or to the embarking upon subjects which are not in a sufficiently ripe condition to be discussed by the Council in full conclave. The minutes of the Council are now taken as read, an economy of time which is fully justified by the fact that they are circulated in type, and there is a general desire on the part of everybody to do what has to be done as expeditiously as possible without sacrificing efficiency. The best endeavours of the Council, however, may be defeated because of the wide range of business before it, for there is one direction in which it will always be very difficult to save time. The hearing of the penal cases cannot be arbitrarily curtailed or adjourned from session to session without good ground and the time taken up by the duty of the Council may be very great. It may be remembered that last session one penal case alone occupied the time of the Council for more than three days. It would have been unfair to the practitioner concerned not to have given to the consideration of the case all necessary time, as upon its issue depended the whole professional position of the impeached man, but, on the other hand, no question of public or professional morality or ethics was concerned which in the smallest degree represented the amount of money spent upon the protracted hearing. At one period in the present session it looked as if the same position would occur again as discussion of one of the penal cases occupied a day and a half out of the short session. It was absolutely necessary that the case should be discussed thoroughly, for the whole future of a medical man was at stake, but had there been three such cases in the penal list the session must again have cost so much money as seriously to affect the balance-sheet of the Council. This is a position which must be very apparent to the General Medical Council which would probably much like to remedy it, but we confess that we do not see what can be done. It has a duty which it must perform and it is the essence of that duty that all important evidence should be admitted, regardless of the time occupied thereby.

Two of the debates in the recent session touched upon important medical politics and serve to show that the Council is alive to the material needs of the medical profession, as well as to the necessity of maintaining such a position between medicine and the public by Act of Parliament that the public may not unduly suffer by the ministrations of unqualified or ignorant persons. Quackery can never be put down by law, while the magnificent invasion by modern medicine of many outlying scientific provinces renders it harder and harder for any Act of Parliament to define what is and what is not a procedure that may with expediency be undertaken by other than a medical man. The debates upon the report of the Unqualified Practice Prevention Committee of the Council and upon the Bill recently read in the House of Lords for the Registration of Nurses proved that the members of the Council are aware of the difficulties, and proved them also to be not afraid to state opinions which are at variance with those held by many general practitioners. The report of the Unqualified Practice Prevention Committee contained information as to the provisions existing for the prevention of medical practice by other than legally qualified persons in all those foreign countries where the experience would have obvious bearing on conditions in Great Britain, and in the report is included a supplementary statement by Dr. A. G. BATEMAN, drawn up from the Medical Acts of the different provinces in the Dominion of Canada and of the different States of the United States of America, the whole making an admirable synopsis of the professional status of medicine in the civilised world. Dr. H. W. LANGLEY BROWNE, having submitted this report, moved that the General Medical Council should transmit to the Privy Council a motion stating that the present Medical Acts do not sufficiently enable "persons requiring medical aid to distinguish qualified from unqualified practitioners" (Medical Act, 1858, Preamble) and requesting the Government to take steps for the appointment of a Royal Commission to inquire into the evil effects of unrestricted practice of medicine and surgery by unqualified persons. The motion was agreed to and for our part we sincerely hope that the Government will be able, and at an early date, to appoint the Royal Commission which is sought. We know perfectly well that there will be an outcry against such an action of the Government on the part of those persons who make a livelihood out of quackery, just as we know that other members of the public, often quite disinterested but almost always ignorant of the true aims of medicine, will set up a cry of medical priestcraft; but the sooner the views of serious and responsible persons upon the evils of unqualified medical practice are placed before the public in an authoritative shape the better it will be for the community. With this action of the General Medical Council we are in full accord and so will all our readers be.

Whether the general practitioners will quite approve the more or less qualified blessing bestowed by the Council upon the Bill for the Registration of Nurses is another matter. Some will say that a Bill for the Registration of Nurses implies the establishment of an inferior order of practitioners having no qualification to practise, and that

THE DIFFICULTY OF DEALING WITH CASES OF SENILE INSANITY: WHERE ARE THEY TO BE ACCOMMODATED?

To the Editor of THE LANCET.

SIR,—In the recent report of the Royal Commission on the Care and Control of the Feeble Minded reference is made to the evidence given by some of the members and officials of the Metropolitan Asylums Board and London County Council that many cases of senile decay are unnecessarily certified as imbeciles and sent to their institutions from the metropolitan workhouses and infirmaries. The report has recently been considered by the Infirmary Medical Superintendents' Society and the members of it feel that it is a matter of regret that no opportunity was given to the medical officers of infirmaries or workhouses to rebut these accusations and to put the position of affairs from their point of view. The society feels that the Commission has been misled and that, if the members of the society had been requested to submit evidence, they would have been able to place before the Commission facts which throw a very different light on the problem of these cases of senile insanity.

The evidence to which the society takes the strongest exception is that of Mr. J. T. Helby, the chairman of the Metropolitan Asylums Board. He is quoted as having said: "The Boards of Guardians appear to send all the senile decay people to us certifying them as imbeciles—a most cruel thing. Our Tooting Bec Asylum is practically nearly full of what are termed imbeciles of that character—nothing less than old men and women suffering from senile decay. In my opinion the proper place for this class of patient would be an infirm ward in the workhouse infirmary where the relatives could visit them." Mr. Helby does not seem to realise that his statement is as grave an accusation against the Metropolitan Asylums Board and its officials as it is against the members and officials of boards of guardians, since it implies that not only are patients being sent to these asylums illegally but that they are also being detained there illegally. If these patients are not insane then they should not be detained but should be returned to the guardians as recovered or as improperly certified. Since this is not done it is to be presumed that, despite Mr. Helby's statement, these cases *are* proper subjects for certification and detention and the only point then in dispute is where they should be detained.

Now these cases of senile insanity are demented and frequently noisy and restless. They disturb and terrify the other old people by their incoherent chattering and by their frequent attacks of screaming and vituperation. At night they are especially troublesome owing to their noisy talking and restlessness. They wander about the ward and often frighten the other inmates by trying to get into their beds. This and their unclean habits, resulting from their demented condition, render them an offence and a most serious source of distress to the other aged sane inmates of the workhouse, and still more so to the sick in an infirmary ward. It is obvious, indeed, that it is impossible to retain such cases in the ordinary wards of a workhouse or infirmary. It is, in fact, illegal to detain them unless separate accommodation from the sane inmates has been provided. Such separate accommodation has not been provided in the workhouses and the reason lies in the existence of the Metropolitan Asylums Board.

Amongst the duties allotted to this Board at its formation were the reception and relief of such insane paupers of the chronic or imbecile class as could be lawfully retained in a workhouse. This definition obviously includes the cases of senile insanity above described, but the only accommodation the Board has provided for them are the asylums at Tooting Bec, Leavesden, and Caterham. The distance of these asylums from many parts of London is undoubtedly a source of great inconvenience to many of the patients' friends, but for this the Metropolitan Asylums Board must take the blame. Instead of providing the simple accommodation that was required in numerous small buildings in different parts of London the Board preferred to erect, at an enormous cost, Tooting Bec Asylum, a palatial institution entirely wasted upon the chronic and imbecile patients for whom it was intended. Thus the whole difficulty of dealing with these patients and the hardship undoubtedly inflicted upon their friends have arisen entirely from the failure of the Metropolitan Asylums Board to provide proper accommodation for the detention of these cases. It would have been far better that the duty of providing the necessary accommodation had been left to individual boards of guardians who would have built then, no doubt, proper wards in the workhouses and infirmaries and provided an adequate staff for them. But it is curious to find the Board, whose duty it is to provide proper accommodation for these cases, attacking the guardians and their officials for sending the very cases for whom it is their duty to provide. Even as it is, only the most troublesome of these cases are sent to Tooting Bec Asylum. Many of them are treated in the observation wards of the workhouse during their acute outbreaks and returned to the general wards when the outbreak has subsided. This is shown by statistics obtained from 14 infirmaries. During 1907 118 cases of insanity were sent to Tooting Bec Asylum from these infirmaries, whilst 294 cases were retained and treated in their observation wards. When one remembers the number of inmates over 70 in the infirmaries and workhouses of London it is really astonishing to find that out of the 832 admissions to Tooting Bec Asylum in 1907 only 213 were over 70 years of age. There can be no doubt that much of the pressure on the accommodation of the Metropolitan Asylums Board for senile and infirm cases is due to the increasing age and infirmity of patients who were admitted to the Board's asylums when able-bodied.

With regard to the similar complaint made on behalf of the London County Council by Sir John MacDougall, two facts must be borne in mind which lead to many senile cases being sent to the county asylums. One is that the asylums of the Metropolitan Asylums Board refuse to admit a case if there is or has been the slightest suggestion that the patient is suicidal or dangerous to others. The other fact is that in many of the infirmaries the certifying justice does not call in the medical officer of the infirmary to examine the cases of alleged lunacy brought to and detained in the infirmary. The result is undoubtedly that many cases are sent to the county asylums which the medical officer would send to the asylums of the Metropolitan Asylums Board or detain in the workhouse for treatment.

One statement of Sir John MacDougall shows that he is not fully acquainted with the law bearing on the detention of lunatics. He is quoted as having said, referring to these old people, "There is a number of patients now certified that need not be certified." The answer to that is, if these cases are *not* insane, then, they ought to be discharged from the asylums, but if they are insane, then, it is illegal to detain them either in the workhouse or asylum unless they are certified. Sir John MacDougall's assertion that these cases are suitable for treatment in the workhouse shows that he is not aware that the workhouses do not possess proper accommodation for their treatment owing to the fact that the boards of guardians have relied upon the statutory obligation of the to advanced middle age, their fingers are literally on the pulse of the public health and their collective investigations should go far to solve some of the most difficult problems of our time. Medical statistics, however accurate the numerical quantities, require elucidation and intelligent comment. In the tables comparing the sickness amongst boys and youths in H.M.S. *Impregnable* and Shotley establishments during the year 1907 we are impressed with the difference in the ratio per 1000 of strength of pneumonia (*Impregnable* 28·36, and Shotley 20·53), of rheumatic fever (*Impregnable* 55·31, and Shotley 38·51), and of diseases of the digestive system (*Impregnable* 211·34, and Shotley 377·40). We should have welcomed from the medical officers in charge any suggestions as to the cause of such divergent ratios which might have confirmed or added to our knowledge as regards the etiology of these diseases and suggested aids to a rational prophylaxis. Again, we have no explanation of the very different ratios of disease at the great naval depots—

at Plymouth ...	21·91 per 1000 of force sick daily.
at Portsmouth ...	31·04 per 1000 „ „ „
at Chatham ...	64·07 per 1000 „ „ „
at Plymouth ...	34·72 per 1000 of force invalided.
at Chatham ...	44·34 per 1000 „ „
at Portsmouth ...	59·94 per 1000 „ „

We hope that motives of economy have not severely limited the information in regard to the health of the navy for the year 1907. These reports are most valuable, not only as concerns the medical archives of the services, but for the world-wide information and instruction of physicians and hygienists, both in their practical duties and as permanent records of the geographical distribution and varying types of disease.

Barber-Surgeons.

ON the 15th inst. the Company of Barbers will celebrate the six-hundredth anniversary of the first recorded appointment of a master of their company. There can be no doubt that the Company had existed for many years before 1308 but in that year it is recorded in the Archives of the Guildhall that "RICHARD LE BARBOUR, dwelling opposite to the Church of Allhallows the Less, was chosen and presented by the barbers of London on Tuesday, next after the feast of Saint LUCY the Virgin, in the second year of the reign of KING EDWARD, son of KING EDWARD before Sir NICHOLAS DE FARNDON, then Mayor of London, JOHN DE WENGRAVE, and other aldermen, to have supervision over the trade of the barbers." It may be mentioned that the feast of Saint LUCY is the 13th of December. The close connexion existing for many years between the surgeon and the barbers and the fact that the present Master of the Worshipful Company of Barbers is Sir JOHN TWEEDY, who was recently President of the Royal College of Surgeons of England, require us to notice this interesting anniversary.

The practice of surgery has arisen in different ways in different times. There can be little doubt that the treatment of wounds received in war first gave rise to a form of surgery. Indeed in the most primitive races now existing, races which are really in the Stone Age, the treatment of wounds has often reached a high state of excellence. Even up to the middle of the fifteenth century little is known of the practice and profession of surgery in England, but there are grounds for believing that they did not differ to any great extent from what obtained generally in France and in Northern Italy. In the fourteenth century England was still connected with France politically, for it possessed the Duchy of Aquitaine. English students were received into the schools of France, and they constituted one of the four scholastic "nations" admitted within the pale of the University of Paris. Many Englishmen studied medicine in Paris and at Montpellier, and English medicine and surgery in the thirteenth and fourteenth centuries were in the main a reflexion of French medicine and surgery, though the organisation of the profession in England was apparently more imperfect but more independent than in France. The facilities for surgical education and training were so few in this country that the earliest known English writers on medicine and surgery all studied in the French schools. GILBERTUS ANGLICUS, who flourished about the year 1200 and wrote "Compendium Medicinæ," the first known English work on medicine, studied at Montpellier. Rather more than a century later JOHN of GADDESDEN, who is mentioned in CHAUCER'S "Doctor of Phisik" and who was the author of "Rosa Anglica," studied medicine at Montpellier under GORDON and surgery in Paris under HENRY of MONDEVILLE. JOHN ARDERNE, a younger contemporary of GADDESDEN and the author of a small treatise "De Fistulis," also studied and probably practised in France. None of these writers, however, exhibited much originality; for the most part they were mere copyists: "*unus non dicit nisi quod alter.*"

All through the Middle Ages medicine and surgery in the West of Europe suffered in the general decline of learning and civilisation which supervened upon the break-up of the Western empire towards the end of the fifth century. The decadence of surgery was accelerated two centuries later by the destruction of the School of Alexandria, by the barbarian invasions of Western Europe, and by the rise and spread of the Mohammedan power. The tradition of Greek science and medicine passed for many centuries into the hands of the Arabians. Though they cultivated medicine with some success they neglected surgery. The Quran forbade the dissection of the human body and human anatomy was therefore almost unknown, so that operative surgery fell into disuse, and external applications, caustics, and cauteries took their place. Towards the end of the eleventh century, however, a brilliant but transient revival of surgery took place in the south of Spain under the influence of ALBUCASIS of Cordova. He wrote a treatise on medicine which contained a chapter on surgery. In this he comments on the timidity and incompetence of the surgeons of his day, and he mentions several instances of disastrous operations performed by surgeons unacquainted with anatomy. The writings of ALBUCASIS were translated into Latin and by the end of the twelfth century they were introduced into Italy, where remnants of learning still lingered. The medical school of Salerno had been famous from the ninth century and in the twelfth century other medical schools arose at Bologna, Naples, and other Italian towns under ROGER of Parma, HUGH sporadic and mild cases are often the precursors of an alarming epidemic. I am, Sir, yours faithfully,

Glasgow, Nov. 30th, 1908. THOMAS COLVIN.

THE STERILISATION OF POTABLE WATERS BY MEANS OF CALCIUM HYPOCHLORITE.

To the Editor of THE LANCET.

SIR,—I read with interest Dr. J. C. Thresh's article under this heading in your last issue, because it serves to corroborate the value of a method of sterilising water which was devised by Captain V. B. Nesfield, I.M.S., some six years ago and which has found very practical application in India. As it is obvious from Dr. Thresh's paper that Captain Nesfield's work is unknown to him, it will be useful to give a brief description of it, extracted from Captain (then Lieutenant) Nesfield's article, entitled "A Chemical Method of Sterilising Water without affecting its Potability," which was published in *Public Health* in July, 1903.

The method is based upon an extensive series of experiments made with bacillus coli, bacillus typhosus, and Shiga's bacillus of dysentery, and the sterilising agent employed is chlorine. The experiments were conducted in the bacteriological laboratories of St. Mary's Hospital. Each experiment was made with one litre of tap water into which had been poured 10 cubic centimetres of a 24, or 48, or 64 hour old broth culture of one of these organisms. Nesfield found that 0·125 gramme of chlorine per infected litre was invariably sufficient to sterilise it in five minutes. The water was dechlorinated subsequently with sodium sulphite in accordance with the formula—

$$Cl_2+H_2O+Na_2SO_3=Na_2SO_4+2HCl,$$

the hydrochloric acid formed being neutralised by the alkali present in commercial sodium sulphite.

The chlorine was first obtained from the liquid gas stored in lead-lined iron cylinders, such as might be used to sterilise supplies in military water-carts. Nesfield then set to work to devise a tablet which could be used to evolve small quantities of nascent chlorine for the use of individuals. For this purpose he found that 1½ grains of bleaching powder mixed thoroughly with ½ grain of sodium bicarbonate would sterilise a pint of water teeming with typhoid or coli bacilli in five minutes. At the end of this time ¼ grain of sodium sulphite rendered it free from chlorine and practically tasteless. The bicarbonate was added to keep the tablet dry and because the CO_2 contained in it acts sufficiently strongly as an acid radicle to liberate the very feebly combined chlorine from bleaching powder (chlorinated lime).

This method has proved successful in the presence of organic matter and Nesfield's sterilising tablets are now widely used by troops and travellers in India. Indeed, the Lieutenant-Governor of Agra and Oudh, in his interesting address on Sanitation in India which you published recently, cited them as one of the causes of the decline in the death-rate from cholera in his provinces.[1] Captain Nesfield devised his method especially for the prevention of water-borne disease amongst troops on active service. It is a remarkable tribute to its value that a practically similar process is now suggested as a means of purifying normal water-supplies.

I am, Sir, yours faithfully,

W. H. WILLCOX, M.D., B.Sc. Lond., F.I.C., D.P.H.,
Lecturer on Public Health to St. Mary's Hospital, W.

Queen Anne-street, W., Nov. 30th, 1908.

HEREDITY WITH SPECIAL REFERENCE TO CANCER, TUBERCULOSIS, AND DISEASE OF THE NERVOUS SYSTEM.

To the Editor of THE LANCET.

SIR,—In the last number of THE LANCET appears what purports to be a speech made by me at the Royal Society of Medicine. This report is inaccurate in many particulars. Words are put into my mouth which not only on this occasion but which on no occasion in my life have I ever used, thus showing that my speech was not only inaccurately reported but actually modified by some one with a totally different vocabulary before publication. I never said, as I am made to say, "that all would agree with Dr. Mercier's remarks concerning mutations." What I did say was "that *not* all would agree with Dr. Mercier's remarks, &c." I never said that my own view was "that there was no truth in Mendelism at all"; what I did say was "that so far the truth of Mendelism has not been *demonstrated* for any one character," and I asked on this very ground for the further collection of facts. I did not say that if the hypothesis of the inheritance of acquired characters were accepted, then I "feared Mendelism of every form collapsed"; what I did say was that if this hypothesis were accepted, then I "feared Mendelism and every theory hitherto proposed of heredity collapsed."

I might cite many other instances in which my statements have been given no meaning or a meaning opposite to that actually expressed by me, but the above will suffice to show why I feel compelled to repudiate entirely this account as representing what I said. It differs very materially from the report I have just received from the Royal Society of Medicine, and I would ask any one who is at all interested in my views to await before criticism the publication of that report. I am, Sir, yours faithfully,

KARL PEARSON.

University College, Gower-street, London, W.C., Nov. 28th, 1908.

⁂ Alas, where great condensations of technical speeches have to be made some speakers must find the reports "inaccurate in many particulars." For the omission of the "not" we apologise sincerely, but the suggestion that it was omitted for the purpose by ourselves or that we modified the report in any way after receiving it from the reporter's hands should not have been made. We join in asking anyone who is at all interested in Professor Pearson's views to await the publication of the report to be published by the Royal Society of Medicine, when time and space will allow of a fuller rendering of the speaker's words and where, it seems, Professor Pearson will be able to revise the proofs.—ED. L.

To the Editor of THE LANCET.

SIR,—Dr. Arthur Latham concludes his article on the Influence of Heredity upon Tuberculosis in THE LANCET of Nov. 21st, p. 1512, with seven conclusions. The first and final ones are very contrary to my acquaintance with the hereditary influence of laryngeal tuberculosis. The two conclusions are: "1. The hereditary transmission of the germ is so infrequent that it is a negligible factor. ...... 7. The theory that there is an inherited predisposition to tuberculosis is based on insufficient evidence." When I was in practice at Canterbury I looked after three sons of a clergyman who all died with laryngeal phthisis. There was one son I did not see who, I was positively sure, had throat consumption. There were two daughters of this family who were in good health all the time I knew them. The mother had died, it was told me, from laryngeal phthisis. The father lived to nearly 80 years of age. My diagnosis of the three cases I saw may be taken as correct, as for some years I was, before going to Canterbury, surgeon to a throat hospital in London. I am, Sir, yours faithfully,

Broadstone, Nov. 25th, 1908. PUGIN THORNTON.

DIVISION OF THE AUDITORY NERVE FOR PAINFUL TINNITUS.

To the Editor of THE LANCET.

SIR,—I am much indebted to Dr. W. Milligan for his letter which appeared in THE LANCET of Nov. 14th, p. 1477, reporting two cases in which he divided the auditory nerve. My paper was written from the neurological and physiological points of view. I did not discuss the surgical advantages of the various operations which have been performed on the auditory nerve because the data before us are as yet quite inadequate to form a judgment of any value. Till further experience has been gained we can only say that probably in some cases the spiral ganglion of Corti or the part of the labyrinth innervated from the ganglion of Scarpa of England, as recited in its charter of 1800, dates its constitutional history, was granted to the Freemen of the Mystery of Barbers of the City of London practising surgery. Provision was made for the appointment of two Masters annually to inspect the instruments of those practising surgery, and no person was allowed to practise surgery in London unless first approved by the Masters of the Company. It is interesting to note that the Senior Warden of the Company when this charter was granted was WILLIAM HOBBES, sergeant-surgeon to the KING. The Guild of Surgeons had maintained its separate existence, but in 1493 it entered into an alliance with the Barbers' Company and eventually in 1540 the two companies were united by Act of Parliament. Four Masters were to be appointed annually, two to be surgeons and two to be barbers; barbers were forbidden to perform any surgical operations, except the drawing of teeth, and surgeons were not to exercise the craft of barbery and shaving. THOMAS VICARY, the sergeant-surgeon to HENRY VIII., and author of a well-known book on anatomy, and who had already been Master of the Barbers Company, was elected the first Master of the United Company. The union thus effected lasted for more than 200 years. At first the privileges conferred on the Company excited some opposition, for an Act was passed allowing unlicensed persons to treat outward sores and swellings with herbs and ointments. In 1684 a petition for the dissolution of the united Company was presented to the KING but no further steps were taken. In 1744 the attempt was renewed and a petition was presented to Parliament for the solution of the union; and in the next year an Act was passed establishing two separate companies. The barbers were allowed to retain the whole of the corporate property, real and personal, with the exception of the Arris bequest and Gale's annuity for anatomy lectures, founded in 1646 and 1655 respectively, and these trusts are still held by the Royal College of Surgeons.

---

[1] THE LANCET, Oct. 24th, 1908, p. 1209.

We have thus traced from the earliest records the connexion existing between the barbers and surgeons of London and in consequence of that association all Fellows and Members of the Royal College of Surgeons of England can rejoice with the members of the Barbers' Company on the occasion of the 600th anniversary of the first record of the existence of that body. The happy association by which, as we have pointed out, the present Master of the Barbers' Company is Sir JOHN TWEEDY, a distinguished and learned surgeon, and very recently President of the Royal College of Surgeons, is yet another reason for the interest of surgeons in this anniversary.

Annotations.

"Ne quid nimis."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the council of the Metropolitan Hospital Sunday Fund was held at the Mansion House on Nov. 30th under the presidency of the Lord Mayor, Sir George Wyatt Truscott. The absence of Dr. James Grey Glover was deeply felt by all present, for he was one of the most conscientious workers for the Fund from its inception in 1872. In addition to the death of Dr. Glover the report of the council referred to the loss which the Fund had sustained during the year by the deaths of Canon Fleming, Sir George B. Bruce, and Mr. C. E. Layton. From a financial point of view the statement of the council was satisfactory, though no stronger word can be used. The total collection for the year was £80,181. The collections in the various places of worship resulted in a sum of £40,000, being £2547 less than in 1907. The council recorded its opinion that in the present state of hospital finances extensions and additions should be discouraged by the Fund except in cases where the hospital could show that it had the means to provide and to maintain them. The Archdeacon of London moved the following recommendation which the general purposes committee made at its meeting on Oct. 7th last:—

> That the Lord Mayor for the time being continue to hold the office of President and treasurer of the Fund, and that a deputy-chairman be appointed, such office to be annual, like those of the chairman of the committees, the present Lord Mayor, Sir John C. Bell, Bart., being asked to become the first holder of the office.

He pointed out that although the Lord Mayor was actually the head of the Fund, he had so many engagements that it was impossible for him to attend every meeting of the Fund. Therefore it was thought desirable that a deputy-chairman should be appointed. This recommendation having been duly seconded and adopted it was agreed that the annual meeting of constituents should be held on Dec. 16th next, and that June 13th, 1909, should be fixed for the next Hospital Sunday. It was also stated that the Fund would receive altogether between £600,000 and £700,000 from the estate of the late Mr. George Herring.

WEST SUSSEX AND THE SALE OF FOOD AND DRUGS ACT.

IT is a matter for congratulation to notice that the increased attention which is being paid to the necessity of a purer milk-supply is having its effect at least in West Sussex. Out of 40 samples of milk taken in the western half of the county during the past quarter only one was adulterated, and at a meeting of the county council on Nov. 27th that body was congratulated upon the result of the labours of the Sale of Food and Drugs Act committee in applying the Act more strictly and with such excellent effect. At a former meeting of the council the sum of money allotted for the purposes of the committee was increased with the object of taking more samples of foodstuffs generally than heretofore. Thus 40 samples of milk were taken, and in view of the controversy over the Board of Agriculture's milk standard the report of Mr. Otto Hehner, the West Sussex county council's analyst, is worthy of record. It will be remembered that a year ago an annotation appeared in THE LANCET under the heading of "Justices and Adulteration," in which attention was called to the fact that the Sale of Food and Drugs Act committee of the council avowed its intention to discontinue its labours if adequate penalties were not imposed in cases where proceedings were taken for adulteration. This action of the committee has been followed with the desired result, and the chairman at the recent meeting of the council said that a great deal of necessary help had been afforded to the council by the action of certain benches of magistrates who had taken up the subject seriously and inflicted such penalties on offenders as had deterred a great number of people from watering the milk which they sold to the poor. Particular complaint was made a year ago as to the decision of certain justices in cases of adulterated cocoa, and the Sale of Food and Drugs Act committee has been continuing its attentions as regards loose cocoa. Three samples, the analyst found, contained nothing but the powder of the cocoa-bean, partly de-fatted. Two samples were mixtures of cocoa, sago starch, and sugar, the asylum and sanatorium. The initiative for the erection of the magnificent asylum was afforded by a group of indefatigable medical men and laymen. When the necessity of building also a new general hospital in Vienna became clear it was decided to use for this purpose the extensive grounds encircling the old lunatic asylum, situated a few hundred yards away from the hospital and to spare no expense in erecting a modern asylum on better grounds. The committee took for its motto, "The best is just good enough for our unhappy wards," and both architect and physicians have interpreted it in a liberal spirit.

The asylum estate comprises an area of about 1,900,000 square yards. One-third of these grounds is reserved for future extensions of the buildings, whilst the remaining 1,200,000 square yards are covered by houses and gardens and streets, for the institution forms a veritable town. A wall and railings, three English miles long, encircle the estate. The soil consists of clay and the sub-soil of marlstone and limestone and the climatic conditions are no less favourable. The pavilions forming the asylum proper are in the middle of the grounds, the sanatorium buildings are on the east side of it, and the administrative buildings on the west side. The asylum has 33 pavilions arranged in four parallel rows, the distance between the pavilions being from 40 to 60 yards, whilst the streets resulting from the arrangement of buildings in rows are from 70 to 85 yards broad. The male and female patients are accommodated in separate blocks on each side of the central buildings which comprise the chapel, social hall, kitchens, and an administrative building. The blocks for curable patients in the asylum consist of two bungalow pavilions with 40 beds in each, five two-storeyed pavilions with 70 beds apiece for patients generally quiet, four two-storeyed houses with 60 beds each for noisy patients, and two three-storeyed buildings each having 100 beds for quiet patients, making altogether 870 beds. The blocks for the incurable inmates consist of four two-storeyed houses, each containing 100 beds, two similar pavilions for refractory patients and cripples with 100 beds each, and two three-storeyed houses with 100 beds each for quiet patients. There are besides two pavilions for tuberculous patients, with 24 beds each, in two-storeyed houses; these contain, also, isolation wards for infectious diseases, with six beds for men and six for women. Quite separated from these pavilions is another with accommodation for 40 patients of the troublesome-dangerous type. 86 patients can be housed in the farmhouses attached to the asylum. They are employed in farmwork with excellent result. The sanatorium is intended for nervous or mentally affected patients of the better classes. They have to pay 10 or 20 crowns (9*s.* to 18*s.*) per day. The equipment is, of course, more luxurious; there are a pavilion for entertainments, a concert hall, and a library, but there are also pavilions for unruly patients or patients with dirty habits; altogether 356 beds in 13 pavilions. The number of beds at present at disposal in the whole institute is 2200, but arrangements have been made which would enable another 800 beds to be placed in the wards at a day's notice, still leaving ample space. Thus 3000 inmates can be accommodated in a very satisfactory manner. Each pavilion is surrounded by a garden and has attached to it rooms for attendants and nurses, quite separated from the wards. The gardens for troublesome or noisy patients are inclosed by a wall 9 feet in height; the semi-quiet patients have gardens with a low rail around them; and the quiet patients are trusted in open gardens. In the sanatorium are all appliances for hydro-electro-therapy, gymnastics, and a cold and warm swimming bath. Air baths and sun baths are also provided for.

A few words must be said about the buildings situated in the central avenue of the asylum. There are four pavilions there. The first one contains the offices and the quarters of the directors and the receiving room for new patients. The next one behind the first named is a large hall for concerts, lectures, receptions, and other indoor amusements. The musical entertainments and indoor games which are held by the patients for the patients are a very successful innovation much appreciated by the afflicted inmates. Behind this building a large kitchen has been installed in its own pavilion. There are 19 large steam kettles of 1900 gallons capacity; open fireplaces and baking ovens are heated by gas, otherwise all the machinery is driven by electricity. A large pantry with spacious storerooms is provided for in the cellar. A refrigerator plant, together with a special ice and soda-water factory, are situated at the wings of this kitchen pavilion which is one of the best equipped, most up-to-date buildings in the institute. The food for 3000 persons is prepared here and distributed in "thermos" vessels to all the 60 pavilions. These "thermos" vessels are constructed with a view to prevent the cooling of the food during the transport which sometimes lasts from 25 to 30 minutes by tram. Behind this pavilion and raised above all other buildings is a large chapel, with an enormous cupola of gilt brass, towering over the mass of buildings and visible many miles into the country. The chapel will seat 1000 persons and service is held there every morning.

Two other features of the asylum must be mentioned. A very important installation is the disinfecting plant, capable of holding 15 cubic metres at a time. It is situated in the administration wing and is worked by steam under pressure of from 12 to 15 atmospheres. If necessary, formaldehyde gas can be used also. The operating theatre is also located away from the patients' pavilions, not far from the church. The laundry can deal with the linen for 3000 persons within 24 hours; all work is done by steam and part of the necessary heat is obtained by the burning of refuse and waste in a special combustion plant. At the farthest end of the institute a pathological laboratory, together with the mortuary and mortuary chapel, have been erected. The area covered by buildings is 75,000 square yards, the rest of the estate being laid down in park, gardens, streets, and orchards. A system of electric trams allows of a swift communication between all pavilions, and 248 telephones connect the physicians and attendants with all the 518 wards and with the offices. There are 216 rooms containing one bed only, 63 rooms with two beds, 31 with three beds, and so on, or in relative proportion. The cubic volume of air allowed per bed is from 40 to 70 cubic yards in the asylum and from 70 to 140 cubic yards in the sanatorium. The windows are equal to from one-sixth to one-third of the surface of the floor. In every floor of the patients' pavilions are a bathroom, built with three or five baths, and a visiting room for friends of the patients. A medical officer's room is also fitted in every pavilion, with all necessary outfit for examination and treatment. Water-closets, with noiseless flush, are fitted in the wards for dangerous or noisy patients, otherwise they are in the corridors. In the pavilions for noisy patients there are altogether 56 side rooms for occasional outbreaks of violence; these measure 15 by 9 feet, and have a xylolith covering on the walls and doubly fastened doors. Most of the troublesome patients are housed in the special pavilion mentioned above. The floor consists of stone slabs covered by linoleum in the wards, of "terrazzo" slabs in the kitchen and baths, and of wood in the entertainment halls, visiting rooms, and staff quarters. The drainage system is in connexion with the main drains of the city. The length of the drainpipes is 8 miles; these can be flushed easily from a reservoir holding 100 cubic yards.

The question of heating 60 pavilions offered many difficulties; it was finally decided to decentralise the heating. Each building has either its own low-pressure steam-heating system, or iron stoves or tile stoves. The latter method has been adopted in all private rooms and localities not occupied by patients. All ovens and all machinery chimneys are fitted with smoke-consuming appliances. Ventilation of the rooms and wards is obtained by ventilators attached to the north corner of the ceiling and all upper windows can be opened on a horizontal axis. In the noisy pavilions an iron railing is fixed between the inner and outer windows, so that they can be kept open safely in summer time. The buildings are lighted by electricity throughout. Where necessary the lamps are fixed high up on the ceiling. Gas is used for lighting the streets and corridors as well as for heating purposes. A "key system" controls the night guards, so that their rounds are checked adequately.

The hospital staff consists of the Primarius (Director), four chief physicians, and 12 resident medical officers, and the staff of nurses and male attendants consists of 760 persons. More than 100 other persons are engaged in the different household occupations. The following statistics are interesting. The yearly rations for the institute have been estimated at 75,000 pounds of sugar, 1,300,000 pints of milk, 10,000 pounds of butter, 500,000 eggs, 250 tons of meat, besides large quantities of bacon, sausages, and lard. The gardens contain 100,000 trees, 30,000 bushes, and 6,000 fruit trees.

are still extant, and some of the great London landlords who derived much of their wealth from what was originally church property might also be approached.

THE KEEPING PROPERTIES OF JAM.

EVERY housewife who makes jam knows that the keeping powers of the several batches made vary. Some samples will go mouldy in a short time, while others will keep in good condition almost indefinitely. The differences observed may be due to some jams being more concentrated than others, as, of course, it is only a concentrated solution of sugar which is antiseptic. It seems certain, also, that cane sugar is a much more satisfactory preservative than glucose, and the argument of jam-makers that glucose is necessary in order to keep the jam from crystallising is put out of court by the fact that if the jam is well made the acids of the fruit should change enough cane sugar into invert sugar to insure against sugar crystals separating. This involves, however, long boiling and nowadays jams, we are told, must be made as cheaply as possible. Hence the superiority of the home-made jam which contains a larger proportion of digestible sugar (and parenthetically, it may be added, more fruit too) than as a rule does the commercially prepared article. It would be a somewhat curious fact if it proved that, after all, jam owed its keeping powers not entirely to sugar but in part to what may be regarded as an artificial preservative—namely, formaldehyde. It has been agreed that formaldehyde is an objectionable preservative for foods on account of its toughening effect upon foods in general and upon protein in particular. And yet it would appear that formaldehyde is readily formed in small quantities by merely boiling solutions of cane sugar, the amount produced depending possibly on the duration of the boiling. According to this, it would not be surprising to find formaldehyde present in many jams as a perfectly unintentional, or even normal, constituent. Its presence, indeed, may be essential to the keeping powers of the jam. The subject deserves further investigation, since analysts may be put off their guard and be the means of instituting proceedings for fraud where no fraud exists. Moreover, there is no evidence that the health of the jam-eating public suffers at all in spite of the small quantities of formaldehyde present in this favourite and nutritious article of diet.

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION.

THIS association is always on the watch lest anything should threaten evil to the health of the community and other localities must envy Manchester the possession of such an organisation. Some time ago an estate called Platt Fields, in Rusholme, was bought by the corporation, always to be used as an open space. Since the purchase, however, various exhibitions, such as an agricultural show, taking up a large space, and an electrical exhibition, have been held on the ground. For such purposes it is well adapted but the committee of the association, at a meeting presided over by Dr. A. Emrys Jones, adopted a motion protesting emphatically against its permanent use for any other purpose than that authorised by the town's meeting. Mr. William Thomson, who has for years devoted much attention to the prevention of lamp accidents, presented an encouraging report (which will be found in THE LANCET of Nov. 28th, p. 1618) showing that a marked diminution has taken place in the number of alleged lamp explosions since the association first entered on the investigation of the subject. The reduced number of explosions indicates great improvement in the construction of lamps, but Mr. Thomson thinks that they would be still further reduced if the length of the wick tube were increased. At the same meeting the honorary secretary, Dr. George Ashton, proposed an important motion, which was seconded by Mr. N. Kolp and carried, "urging on the authorities that the time has come when the youth of the country should be required to submit to systematic physical training up to the age of 22." Service in the Territorial Army was recommended as one means of effecting the wished-for improvement in the national physique. Quite apart from any military considerations, though they may prove to be most important, the improvement that might be hoped for in the condition as to health and general bearing of a large proportion of our youths and young men is earnestly to be sought for, as it is urgently needed. If the average be taken of the crowds of workers coming out from the mills and works of our busy towns, or of the loafers slouching at the street corners, it is obvious that there is more decadence than progression shown in their physical condition. It is permissible also to hope that the discipline and the subtle effect of acting in concert with others may do something to supplement the teaching in our elementary schools, which seems to impart a smattering of sundry "isms" but to leave courtesy, or even decent manners, as matters not worth considering in these progressive days. If these things are not beyond hoping for, what an improvement may some day be found in the character of our citizens. But will the authorities be moved to action?

DISPLACEMENT OF THE LARYNX AS A SIGN OF ANEURYSM OF THE ARCH OF THE AORTA.

AT the meeting of the Académie de Médecine of Paris on Nov. 10th, M. E. Boinet reported the following remarkable case. A night watchman, aged 59 years, was attacked in April, 1904, by a band of ruffians, struck and kicked on the upper part of the chest, gagged, bound, and thrown into water from which he was rescued almost dead. An attack of influenza complicated by broncho-pneumonia followed. He slowly recovered and some weeks later during a violent attack of coughing he felt an acute pain at the internal part of the second right intercostal space and a pulsatile tumour appeared at this point. Some months later he went to the Hotel-Dieu with all the signs of an aneurysm of the ascending part of the arch of the aorta projecting in the second right intercostal space, covered by thin, tense skin threatening to rupture. It was accompanied by expansile pulsation and a systolic murmur. There was no history of syphilis. Under rest in bed, milk diet, large doses of potassium iodide, and subcutaneous injections of gelatin considerable improvement took place and he resumed work. In June, 1905, he returned to hospital with considerable distension of the veins of the neck, particularly of the right external jugular vein which when emptied by drawing the finger upwards along it and continuing the pressure on its upper end showed regurgitant waves of blood. The radial pulses were regular, equal, and synchronous. The heart was slightly hypertrophied and a mitral regurgitant murmur was heard. The same treatment was followed and he again resumed work. In May, 1906, his general condition was good but the aneurysm had made progress. It had pushed forward the first two ribs and upper part of the sternum, caused subluxation of the clavicle, and projected in the right supraclavicular and suprasternal fossæ. The aneurysm further progressed and pressed directly on the larynx, displacing it downwards and to the left. In March, 1907, there was marked dyspnœa, accompanied by stridor and spasms of the tongue, larynx, and œsophagus. Symptoms of compression of the recurrent laryngeal nerve followed; the voice was lost for two or three hours and then after some attacks of coughing the expectoration of mucus returned. Later the voice became stifled, hoarse, and bitonal. The laryngoscope showed complete paralysis of the left vocal cord.

Cadbury so generously gave for the purpose, requires extensive alterations and additions before it will be available for its purpose. It is estimated that the provision of the necessary sanitary blocks and general equipment will cost at least £5000. The necessity for the hospital is rendered evident by the fact that the Crippled Children's Union has registered in its books 1000 children, 400 of whom are suffering from tuberculous bone disease, and of the latter 100, who are in the acute stage, are being treated at home under very disadvantageous conditions. There is at present very little hospital accommodation for children suffering from hip and spinal diseases which require prolonged treatment and the committee wishes to increase the facilities for such cases as soon as possible, but the rate of the progress which it will be able to make depends entirely on the support of the public.

Prevention of Cruelty to Children.

Though the prevention of cruelty to children is not directly medical work it results indirectly in an amelioration of the public health. It relieves many children from bodily and mental suffering and it tends to elevate some parents' conceptions of their duties and responsibilities. The society which undertakes the work is therefore in a sense a medical agent, and it is pleasant to note that our Birmingham branch is extending the scope of its work by engaging the interest and services of individuals living in outlying districts. It is also helped by the lady inspectors of health, of whom there are about 17 associated with the health department of the city. These ladies make house-to-house visitations in the districts where the society meets with most of the cases in which it is necessary to interfere, and they are instrumental not only in discovering cases which would otherwise not be brought to light but also in preventing much unnecessary hardship. That the services of the society are very necessary in this district is demonstrated by the annual report of the Birmingham branch which was presented at the annual meeting held in the council house last week. During the year 1179 complaints were made to the branch and of these 1028 proved to be well established and the children affected numbered 3710. In the majority of the cases warnings proved sufficient, in 51 cases the children were placed in better conditions either with relatives or in emigration homes, and 41 people were prosecuted, convictions being obtained in all but two cases. The record is excellent and the small proportion of prosecutions indicates that the society is acting on good lines.

The Dudley Guest Hospital.

The annual report of the Dudley Guest Hospital shows that the bequest of the late Mr. Hugh Lewis's estate has not been an unmixed blessing, for the knowledge of the bequest had apparently caused many people to cease or to reduce their subscriptions, with the result that the yearly income of the hospital has fallen from £4183 in 1907 to £3822 in 1908, that is to the lowest point it has attained since 1905. The number of in-patients treated during the year was 950. The average cost per bed was £64 5*s.*, and the cost per patient £4 9*s.* 4*d.* In the eye department 125 cases were admitted during the year, and the average cost per case was £3 4*s.* The financial result of the year's work is that the adverse balance has been increased to £902; this the committee thinks is a very serious matter and it earnestly appeals to the friends of the hospital for more support.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospitals and Port Sanitary Committee: Sir William Hartley and the Treatment of Tuberculosis.

Mr. John Utting, M.R.C.S. Eng., has been re-elected chairman of the hospitals and port sanitary committee of the city council, and in taking the chair alluded to the efficient measures which were adopted to deal with the recent outbreak of plague in the port. In this matter the committee had not only to safeguard the health and lives of the citizens but also to prevent the dislocation of a world-wide commerce. They were working under the international convention of Paris, and if all the signatories were loyal to the convention the risks would be reduced to a minimum. As to the hospitals, they had now under treatment 983 cases, against about 600 this time last year, and during the year there had been an increase of 1000 cases, due almost entirely to scarlet fever of a mild type. 87 cases of pulmonary tuberculosis had been treated at the Fazakerley hospital. The results were eminently satisfactory, and the medical officer recommended that the beds available for that disease should be increased from 25 to 50. It was important that they should get hold of cases in an early stage. The offer of Sir William Hartley to give £5000 for a fund to assist those dependent on patients undergoing treatment in the early stage was a generous one, and he (the chairman) suggested that they should invite representatives of the health committee and the consumption hospital and Sir William Hartley to a conference on the subject, which, it appears, had already been done.

The Liverpool Milk-supply: Caution to Dairymen.

Dairymen who send tuberculous milk to Liverpool or those who neglect to notify the existence of cows showing signs of infection will in future have their names and addresses printed and published in reports delivered to the members of the city council and available to any ratepayer. The dread of publicity, being far greater than the fear of a monetary penalty, will be an important factor in preserving the purity of the milk-supply.

The New Chancellor of the University of Liverpool.

The annual meeting of the court of governors of the University was held on Nov. 28th in the town hall, the Lord Mayor presiding, when the Earl of Derby was unanimously elected chancellor of the University in the room of the late Earl of Derby, K.G.

Sir Rubert Boyce and the Hairdressers' Association.

A few days ago a large party of the members and friends of the Liverpool Hairdressers' Association were afforded the opportunity of inspecting the various departments of the University. Among the University staff who took charge of the visitors in their tour of inspection were Sir Rubert Boyce, Professor Wilberforce, and Professor Watkinson. Sir Rubert Boyce impressed on the association, as a body of men who were constantly coming in contact with all classes of people, the desirability of knowing something about the origin of particular diseases. He suggested that they should try to obtain a course of lectures at the University which would be useful to them in their business and promised to assist them in every way that he could. Vice-Chancellor Dale, in a letter to the secretary of the association, said he was glad to hear from them that the visit had proved interesting. He also promised to make inquiries as to the feasibility of carrying out Sir Rubert Boyce's suggestion.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Inspection of Meat.

THERE were issued last week by the Local Government Board for Scotland regulations that have been framed under the provisions of the Public Health (Regulations as to Food) Act, 1907. This Act is entitled "An Act to enable Regulations to be made for the Prevention of Danger arising to Public Health from the Importation, Preparation, Storage, and Distribution of Articles of Food." The regulations that have been prepared by the Local Government Board are of two kinds and are entitled "Unsound Food Regulations" and "Foreign Meat Regulations" respectively. The unsound food series deals with articles of food brought by ship to any port in Scotland from any place outwith this country, and have been framed with the object of securing that such articles of food shall be dealt with at the port of discharge. The regulations give the medical officer of health power to examine articles of food on board the ship if he considers it necessary. The procedure to be adopted is much the same as that prescribed in Section 43 of the Public Health (Scotland) Act, 1897, at present in force. If the medical officer of health is of opinion that the article of food is unsound he is given power to seize and to carry it away and to obtain a warrant of condemnation from a sheriff, magistrate, or justice. In are still extant, and some of the great London landlords who derived much of their wealth from what was originally church property might also be approached.

THE KEEPING PROPERTIES OF JAM.

Every housewife who makes jam knows that the keeping powers of the several batches made vary. Some samples will go mouldy in a short time, while others will keep in good condition almost indefinitely. The differences observed may be due to some jams being more concentrated than others, as, of course, it is only a concentrated solution of sugar which is antiseptic. It seems certain, also, that cane sugar is a much more satisfactory preservative than glucose, and the argument of jam-makers that glucose is necessary in order to keep the jam from crystallising is put out of court by the fact that if the jam is well made the acids of the fruit should change enough cane sugar into invert sugar to insure against sugar crystals separating. This involves, however, long boiling and nowadays jams, we are told, must be made as cheaply as possible. Hence the superiority of the home-made jam which contains a larger proportion of digestible sugar (and parenthetically, it may be added, more fruit too) than as a rule does the commercially prepared article. It would be a somewhat curious fact if it proved that, after all, jam owed its keeping powers not entirely to sugar but in part to what may be regarded as an artificial preservative—namely, formaldehyde. It has been agreed that formaldehyde is an objectionable preservative for foods on account of its toughening effect upon foods in general and upon protein in particular. And yet it would appear that formaldehyde is readily formed in small quantities by merely boiling solutions of cane sugar, the amount produced depending possibly on the duration of the boiling. According to this, it would not be surprising to find formaldehyde present in many jams as a perfectly unintentional, or even normal, constituent. Its presence, indeed, may be essential to the keeping powers of the jam. The subject deserves further investigation, since analysts may be put off their guard and be the means of instituting proceedings for fraud where no fraud exists. Moreover, there is no evidence that the health of the jam-eating public suffers at all in spite of the small quantities of formaldehyde present in this favourite and nutritious article of diet.

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION.

This association is always on the watch lest anything should threaten evil to the health of the community and other localities must envy Manchester the possession of such an organisation. Some time ago an estate called Platt Fields, in Rusholme, was bought by the corporation, always to be used as an open space. Since the purchase, however, various exhibitions, such as an agricultural show, taking up a large space, and an electrical exhibition, have been held on the ground. For such purposes it is well adapted but the committee of the association, at a meeting presided over by Dr. A. Emrys Jones, adopted a motion protesting emphatically against its permanent use for any other purpose than that authorised by the town's meeting. Mr. William Thomson, who has for years devoted much attention to the prevention of lamp accidents, presented an encouraging report (which will be found in The Lancet of Nov. 28th, p. 1618) showing that a marked diminution has taken place in the number of alleged lamp explosions since the association first entered on the investigation of the subject. The reduced number of explosions indicates great improvement in the construction of lamps, but Mr. Thomson thinks that they would be still further reduced if the length of the wick tube were increased. At the same meeting the honorary secretary, Dr. George Ashton, proposed an important motion, which was seconded by Mr. N. Kolp and carried, "urging on the authorities that the time has come when the youth of the country should be required to submit to systematic physical training up to the age of 22." Service in the Territorial Army was recommended as one means of effecting the wished-for improvement in the national physique. Quite apart from any military considerations, though they may prove to be most important, the improvement that might be hoped for in the condition as to health and general bearing of a large proportion of our youths and young men is earnestly to be sought for, as it is urgently needed. If the average be taken of the crowds of workers coming out from the mills and works of our busy towns, or of the loafers slouching at the street corners, it is obvious that there is more decadence than progression shown in their physical condition. It is permissible also to hope that the discipline and the subtle effect of acting in concert with others may do something to supplement the teaching in our elementary schools, which seems to impart a smattering of sundry "isms" but to leave courtesy, or even decent manners, as matters not worth considering in these progressive days. If these things are not beyond hoping for, what an improvement may some day be found in the character of our citizens. But will the authorities be moved to action?

DISPLACEMENT OF THE LARYNX AS A SIGN OF ANEURYSM OF THE ARCH OF THE AORTA.

At the meeting of the Académie de Médecine of Paris on Nov. 10th, M. E. Boinet reported the following remarkable case. A night watchman, aged 59 years, was attacked in April, 1904, by a band of ruffians, struck and kicked on the upper part of the chest, gagged, bound, and thrown into water from which he was rescued almost dead. An attack of influenza complicated by broncho-pneumonia followed. He slowly recovered and some weeks later during a violent attack of coughing he felt an acute pain at the internal part of the second right intercostal space and a pulsatile tumour appeared at this point. Some months later he went to the Hotel-Dieu with all the signs of an aneurysm of the ascending part of the arch of the aorta projecting in the second right intercostal space, covered by thin, tense skin threatening to rupture. It was accompanied by expansile pulsation and a systolic murmur. There was no history of syphilis. Under rest in bed, milk diet, large doses of potassium iodide, and subcutaneous injections of gelatin considerable improvement took place and he resumed work. In June, 1905, he returned to hospital with considerable distension of the veins of the neck, particularly of the right external jugular vein which when emptied by drawing the finger upwards along it and continuing the pressure on its upper end showed regurgitant waves of blood. The radial pulses were regular, equal, and synchronous. The heart was slightly hypertrophied and a mitral regurgitant murmur was heard. The same treatment was followed and he again resumed work. In May, 1906, his general condition was good but the aneurysm had made progress. It had pushed forward the first two ribs and upper part of the sternum, caused subluxation of the clavicle, and projected in the right supraclavicular and suprasternal fossæ. The aneurysm further progressed and pressed directly on the larynx, displacing it downwards and to the left. In March, 1907, there was marked dyspnœa, accompanied by stridor and spasms of the tongue, larynx, and œsophagus. Symptoms of compression of the recurrent laryngeal nerve followed; the voice was lost for two or three hours and then after some attacks of coughing the expectoration of mucus returned. Later the voice became stifled, hoarse, and bitonal. The laryngoscope showed complete paralysis of the left vocal cord.

arrangement to which they objected and the Board also proceeded to appoint the medical officers and the midwives for those districts without regard to the right of the guardians to make the appointments. In giving judgment the Lord Chief Justice, after discussion of some technicalities, stated his opinion that "the paramount discretion was with the Local Government Board. The real substance of this is that the rearrangement was for the benefit of the people of the district." Mr. Justice Gibson referred to the fact that the guardians never gave any reply to the Local Government Board but simply characterised the official proposal as "ridiculous." Mr. Justice Kenny concurred with the views of the other judges.

Ulster Medical Society.

The annual dinner of the Ulster Medical Society was held in the Medical Institute, Belfast, on Nov. 26th, Mr. T. S. Kirk, the President, being in the chair. The President gave the toast of "The King" and then "The Lord Lieutenant of Ireland," to which the Lord Mayor of Belfast (Sir Robert Anderson) replied, both the Lord Mayor and the President laying stress on the work done by Lady Aberdeen in the anti-tuberculosis campaign. The next toast, "Our Guests," was given in a very humorous way by Mr. R. J. Johnstone, and to it Mr. A. J. Horne (President of the Royal College of Physicians of Ireland) and Mr. John Lentaigne (President of the Royal College of Surgeons in Ireland) responded. Finally the toast of "The President" was given by Professor W. St. C. Symmers, to which Mr. Kirk replied. During the evening some excellent songs were sung by Dr. J. E. MacIlwaine and Mr. R D. Patterson. This annual reunion of the Ulster Medical Society, at which about 60 were present, was in every respect a great success and the arrangements were admirably carried out by Dr. H. Stevenson (honorary secretary of the society).

The Sewage Pollution of Belfast Lough.

On Nov. 24th a Local Government Board inquiry was opened in the City Hall, Belfast, by Sir J. A. MacCullagh (medical inspector), with whom sat Mr. P. C. Cowan, M. Inst. C.E. (chief engineering inspector), into an application of the city council of Belfast for a loan of £112,300 for the purpose of carrying out a scheme for the purification of the sewage of the city and for completing the Sydenham and Knock drainage scheme. The inquiry lasted until the afternoon of the 27th, when it was adjourned until Dec. 15th. Several witnesses (the city surveyor, the city accountant, the chairman and another member of the improvement committee) were examined. There is a very formidable opposition to this scheme on the part of the Harbour Commissioners, the residents on the shores of Belfast Lough, the Castlereagh rural district council, the Belfast rural district council, the Holywood urban council, and others, the main lines of opposition being two--first, that the scheme was incomplete and partial and would only lead to a purification of from 20 to 30 per cent.; and secondly, that it did not comply with the statutory obligations of the Belfast corporation as defined by the Act of 1899. A curious fact came out by the city accountant estimating the population of Belfast during the present year as 380,344, while at the Health Commission the chairman of the public health committee estimated the population of Belfast for 1906 as 388,159, showing a remarkable decrease in two years.

Vice-Regal Visit to Donegal.

The Lord Lieutenant of Ireland and Lady Aberdeen have spent the past week in various parts of the north-west of Ireland, opening a Tuberculosis Exhibition in Donegal on Nov. 24th, after visiting Belleek on the previous day. At Donegal Mr. H. T. A. Warnock read an address cordially welcoming them and referring to the gratitude of the Irish people to the Countess for her great exertions to promote Irish industries and thanking her for her energy in prosecuting the anti-tuberculosis campaign. The Lord Lieutenant also spoke and the Countess of Aberdeen declared the exhibition open. Subsequently it was decided to open a branch in Donegal of the Women's National Health Association of Ireland. During the remainder of the week their Excellencies visited various parts of the north west—Trillick (where the tuberculosis van "Eire" was started on its tour throughout Ireland), Omagh (where the County Hospital was inspected), Enniskillen (where Lady Aberdeen visited the County Infirmary with its open-air consumption chalet), and Ballyshannon (where the Tuberculosis Exhibition had moved from Donegal). The enterprise shown in spending a week—at a most inclement part of the year—in an out of the way district of the country so as to promote the Women's National Health Association of Ireland and to inspect and to encourage various native industries is recognised by all parties.

Dec. 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Pneumonia occurring Simultaneously in Husband and Wife.

AT a meeting of the Hospitals Medical Society held on Oct. 30th M. Widal related on his own behalf and on that of M. Chauffard, two cases of pneumonia occurring simultaneously in husband and wife. Both patients had drunk upon the same day, in accordance with their usual custom, a quantity of cold water. On the following day both patients were attacked with pneumonia at a few hours' interval. The disease ran a similar course in both, the two crises occurred on the same day and the two temperature charts were similar. It is difficult to suppose that in these two cases the one was infected by the other, as the rigor in the one so closely followed that in the other. Neither were there any influences such as fatigue or insanitary conditions present, so it would seem as if the infection was to be put down to the water. On Nov. 6th M. Netter referred to the subject and gave it as his opinion that in cases of simultaneous pneumonia in husband and wife the virulence of the pneumococci present in the mouth might be exalted by cold, such as, for instance, the ingestion of cold water.

The Light Treatment of Lupus.

At the November meeting of the Society of Dermatology and Syphilography M. de Beurmann and M. Degrais exhibited some apparatus used in phototherapy. At the St. Louis Hospital there is now a department in which four Finsen lamps are available capable of treating 128 patients per day. The two pieces of apparatus shown at the meeting were the one a method for easily focussing the lenses for the light from an electric arc, and the other a method of keeping up regular automatic compression of the region treated.

Altitude and Sunlight Cure of Cutaneous Tuberculosis.

At the same meeting of the same society M. Hallopeau gave an account of the results obtained by M. Rolier in the treatment of various tuberculous affections, and in particular that of lupus, by the rays of the sun at a high altitude. The patients are exposed almost naked and the effects are excellent. It would seem that the pigmentation which results from exposure to the sun is of great importance in rendering the penetration of the rays more complete. M. Balzer gave an account of a case of lupus of the nose which had been cured by exposure to the rays of the sun at sea level. M. de Beurmann said that this method gave good results in gummata and certain forms of cutaneous tuberculosis. A high altitude was, however, preferable, for there the chemical rays of the sun were more active and the heat rays less so.

Cancer of the Rectum and Fulguration.

On Oct. 24th at the Society of Medicine M. Bizard gave an account of a case of a man, aged 41 years, who had suffered for two years from cancer of the rectum. Various surgeons had agreed that the only thing to be done was to make an artificial anus. Treatment of the growth by fulguration was begun in the month of November, 1907. The results were excellent. The local trouble disappeared for the most part and the patient has gained 26 pounds in weight since the treatment was begun. This case and others like it would seem to show that fulguration is one of the best methods of treatment for cancer, even for those cases which are considered inoperable.

Atoxyl in the Treatment of Malaria.

M. Vassal has been able to study the effects of atoxyl in 17 cases of malaria at the native hospital of Nhatrang in Annam. He uses a 10 per cent. solution which he injects deeply into the muscles of the thigh, the dose being 1 gramme of atoxyl. In other cases he gives the salt by the mouth in doses of 10 centigrammes per day for ten days and upwards. Employed by itself in these large doses, atoxyl is neither antipyretic nor antiparasitic, but if

21,000,000; while of 1000 children born in these six rural counties only 63 died under the age of one year, the mean proportion in the 218 towns was 142 per 1000. During last summer quarter 11,119 deaths in England and Wales were referred to diarrhœa, of which 8498 occurred in the 218 largest towns, and but 2621 in the remainder of England and Wales, with a population of about 14,000,000, mainly rural, but including all urban districts with populations under 20,000. The annual death-rate from diarrhœa during last quarter in the whole of England and Wales was equal to 1·25 per 1000, against 2·07, the average rate in the ten preceding corresponding summer quarters. The annual death-rate from diarrhœa last quarter was 1·71 per 1000 in the 76 largest towns, ranging from 0·03 and 0·06 in Hastings and Bournemouth, to 4·20 in Hull, 4·28 in Middlesbrough, 4·50 in Burnley, and 6·09 in Rhondda. In the 142 smaller towns the mean annual diarrhœa rate was equal to 1·25 per 1000 and in the remainder of England and Wales the mean rate did not exceed 0·73 per 1000. In order, however, to show more clearly the comparative immunity from summer diarrhœa in rural populations, it should be noted that in the six essentially rural counties enumerated above, although they include several populous urban districts, the mean annual death-rate from diarrhœa during last quarter did not exceed 0·16 per 1000 and was less than one-tenth of the mean rate that prevailed in the 76 largest towns. Striking as is this contrast, however, these figures underestimate the comparative immunity from fatal infantile summer diarrhœa in rural districts, not only because it is at present impossible to exclude from the statistics for rural counties the facts relating to urban districts situated therein, but because it is also impossible to ascertain from the Registrar-General's returns how many of the deaths attributed to diarrhœa in administrative counties and sanitary districts are of infants under one year of age or of children aged under five years. It appears from the Registrar-General's last issued annual report relating to 1906 that in the whole of England and Wales 92·2 per cent. of the deaths attributed to diarrhœa in that year were of children aged under five years and 74·9 per cent. of infants under one year of age; but the proportions of the deaths of young children from diarrhœa are probably much larger in the summer quarter of the year.

CATALYSIS VERSUS VITAL ENERGY.

As is well known, the discovery of a method of synthesising urea was the first step in the destruction of the "vital theory" and it was soon found that many other products of animal metabolism could be built up from inorganic materials without the aid of vital processes. Indeed, the term "organic" chemistry had not long been adopted before it became a misnomer. Many reactions were explained by the assumption of a "vital energy" and the action of enzymes was generally attributed to a vital force rather than a purely chemical change. In this connexion it is of interest to refer to a communication from the Johns Hopkins University by Mr. S. F. Acree on the Catalytic Reactions Induced by Enzymes.[1] His work, supplementing that of Dr. Hudson and other investigators, serves to clear up much of the mystery that hitherto has surrounded the action of enzymes. According to the modern view the addition of an enzyme to a reacting system brings about a catalytic change because the enzyme unites with some constituent, called a "substratum," of the reacting system and forms a new compound which furnishes the same end-products more or less readily than does the substratum. This conception harmonises with the facts connected with enzymic catalysis and renders unnecessary the assumption that an enzyme stores up within itself a vital energy which is given up to the reacting system and, perhaps, after transformation causes an acceleration of the reaction similar to that produced by heat, light, and other physical agents. The new theory of catalysis clears up the mystery of catalytic action and points to the probability that all organic reactions are essentially like the inorganic reactions. The vital energy theory, on the other hand, fails to harmonise with some known facts and there is no corroborative evidence that enzymes store the energy necessary to bring about the reactions which they set up. For example, O'Sullivan and Tompson showed that invertase can catalyse at least 100,000 times its own weight of cane sugar without losing its reactivity to a measurable extent. If it be assumed that the action of the enzyme is due to the possession of a vital energy invertase would be compelled to give off enormous quantities of energy, perhaps as much as radium is capable of producing. While allowing that the question requires to be tested further by experiment Mr. Acree holds that the discoveries of the last few years have removed the doctrine of vital energy beyond the reasonable limits of possibility. He who would revive this creed must first offer new facts.

RESUSCITATION OF THE APPARENTLY DROWNED.

Early in the present year the chief surgeon of the Metropolitan Police, Mr. Clinton T. Dent, requested the Royal Society of Medicine to make a pronouncement as to the best method now available for the resuscitation of the apparently drowned. The request was occasioned by the fact that the Royal Life Saving Society, the influence of which on matters relating to rescue and resuscitation is coextensive with the British Empire, had adopted the method recently recommended by Professor E. A. Schäfer, while the Royal Humane Society and Metropolitan police continued to employ the method introduced by the late Dr. Silvester. The council of the Royal Society of Medicine, following the custom of the Royal Medical and Chirurgical Society, nominated the following as a committee to report on the matter: Sir William S. Church (President), Dr. F. H. Champneys, Mr. F. Warrington Haward, Dr. Leonard E. Hill, Professor Arthur Keith, Professor E. H. Starling, Dr. Arthur Latham, and Mr. Herbert S. Pendlebury, the two last named acting as honorary secretaries, while Mr. J. Y. W. MacAlister acted as official secretary. The committee, the report of which has just appeared, recommends Professor Schäfer's method as preferable to either that of Marshall Hall or of Silvester for the resuscitation of the apparently drowned. The recommendation is somewhat unexpected when we remember the criticism to which Professor Schäfer's method was subjected when brought before the Royal Medical and Chirurgical Society in December, 1903. The reasons which induced the committee to prefer the Schäfer method are: (1) the prone position favours the escape of water and mucus from the mouth and trachea; (2) it gives a larger exchange of respiratory air; (3) it gives an effectual upward pressure on the diaphragm, thus stimulating the heart; and (4) there is in Schäfer's method less risk of injury to the abdominal viscera or to the ribs. It is sincerely to be hoped that the finding of the last resuscitation committee may have a more abiding value than those of its four predecessors. Certainly more than one of the reasons given for the adoption of the Schäfer method are open to criticism, especially the second; even Professor Schäfer does not claim a superior but only a sufficient respiratory exchange for his method. It is a matter of regret that the records of the Royal Humane Society, kept for nearly 150 years and the cryoscopic work. Bechmann's apparatus is probably the simplest to use and gives very accurate results. The lecturer exhibited this apparatus and demonstrated to the society the determination of the freezing point of some serum from a case under observation. Normally, he said, the freezing point should be $-0{\cdot}56^\circ$ C. ($\delta = 0{\cdot}56$) for the blood. For the urine it should be from $-1{\cdot}2^\circ$ to $-2{\cdot}5^\circ$ C. ($\Delta = 1{\cdot}2$ to $2{\cdot}5$). It was observed that even after an intravenous infusion of 2000 cubic centimetres, the freezing point of the blood would become normal in four hours. He concluded that cryoscopy indicates the extent to which the kidneys are getting rid of the effete products of metabolism and that in certain cases of unilateral renal disease it was a most valuable aid to differential diagnosis.

The Care and Treatment of Epileptics.

At the opening of the new Hospital for Epileptics and Lunatics Dr. Donath gave a short address on the care and treatment of epileptics. He remarked that society was wholly responsible for the conditions which gave rise to epilepsy and it was the duty of society at large to contribute to the care of the unfortunate victims of those conditions of its own creation. More than 85 per cent. of epileptics were hereditary sufferers, and alcoholism in the parents was responsible for the great majority of cases. It had been said that not less than one in every three children of alcoholic parents suffered from epilepsy. Colonisation of the sufferers was the only way in which epileptics could be cared for properly. He said that up to now they had been shut up with the insane in most of the lunatic asylums in Hungary, a state of affairs which was unfair to both classes of patients. The majority of physicians were willing to admit that purely medical or surgical treatment was of little or no value except in very exceptional cases. More had been done by insisting on a truly hygienic mode of living, strict regulations of the habits of life, and particularly by suitable and interesting employment and surroundings.

New Regulations for School Hygiene.

Under the direction of the Minister of Education the Board of Education has drafted a new set of regulations for the supervision of school children by medical practitioners who will periodically examine the health of the children attending the schools, as is the case at present in Austria. As the chief object of the regulations is the prevention of disease they refer rather to prophylactic work than to the treatment of sick children. The school medical officers will have control in all matters relating to the physical and psychical well-being of the pupils, they will supervise the gymnastic exercises, and before each school term they will examine the children as to the state of the eyes, ears, throat, and spine, so as to discover any who may be unfit for the work of the class in regard to singing, gymnastics, and needlework. First aid may be given if necessary but otherwise medical treatment is not to be undertaken. The proposed remuneration is almost as much as in Austria, about £2 per class per annum. It is also proposed to appoint special practitioners for prophylactic work alone.

Treatment of Eclampsia.

At a meeting of the Nagyvárad Medical Society Dr. Révész laid down the principles of treatment of eclampsia. They consist only in controlling the convulsions and eliminating the toxins. Chloroform is the most trustworthy agent for controlling the convulsions but its injurious effect on the cardiac and vascular systems precludes its use for any extended period. Morphine restricts the eliminative function and prolongs the post-eclamptic stupor. Chloral controls the convulsions, is less toxic than morphine, has no injurious effects on secretion, and can be continued for long periods. Dr. Révész considers the most satisfactory method to be the employment of chloroform until chloralisation is complete. Veratrum would seem to meet the indications but has not been sufficiently tried. To secure elimination of the toxins catharsis by means of calomel, croton oil, or high flushings of the colon is of prime importance. Fluids by the mouth and rectum and cupping over the kidneys will stimulate diuresis. Diaphoresis is best obtained by the hot-air bath or hot pack. The uterus should be emptied as speedily as possible by forceps or version if the cervix is dilated. A closed cervix should be dilated by the fingers or rubber bags. If the cervix is rigid and "cartilaginous" Cæsarean section, vaginal or abdominal, should be performed.

Nov. 27th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Malarial Fever.

THE mortality returns show that the deaths attributed to "fever" in the North-West Provinces amount to approximately two-thirds to three-quarters of the total number of reported deaths. The death ratio from "fever" per 1000 of the population in the period 1883–92 was 24·41; it rose in the next decade to 25·17, and in the five years 1903–07 to 26·88. After making allowance for lung affections and tuberculosis, and in late years for undiagnosed plague, a large proportion of these deaths must be undoubtedly put down to malaria; the exact proportion it is impossible to define, but a high death-rate attributed to "fever" may be safely taken as an indication of the prevalence of malaria. And not only are many deaths directly attributable to that cause, but the prevalence of malaria by undermining the stamina of the people makes them more susceptible to fall victims to other diseases. In attempting to improve the conditions under which the people live, the special attention of the Government should be devoted to measures for minimising the prevalence of malaria. With the object of investigating the causes of malaria in the districts of the provinces and of making recommendations for removing them as far as this can be done, the Lieutenant-Governor has decided, as stated by him in his speech at the opening of the recent sanitary conference, to place an officer on special duty, and has for this purpose selected Major J. C. Robertson, I.M.S., a deputy sanitary commissioner in these provinces, now on leave. Major Robertson will take up this investigation immediately. He will be under the control of the sanitary commissioner who will furnish him with detailed instructions approved by the Lieutenant-Governor for his guidance in making the inquiry intrusted to him. The latter looks to district and other officers to afford him all possible assistance in carrying out this work and trusts that he may also be accorded the coöperation of all non-official residents interested in the improvement of the conditions of life in the provinces.

Malaria in Calcutta.

Some interesting remarks concerning malaria in this city are made by Dr. T. F. Pearse, health officer of the Calcutta corporation, in his report on the administration of his department for the past official year. Dr. Pearse states that the proportion of deaths from malaria is very small in Calcutta compared with that in the province of Bengal, and the difference is not entirely explained by the more accurate registration of the causes of death now made in the city. Comparatively little true malaria is "caught" within the limits of Old Calcutta, although the suburbs are more fever-ridden than the central parts, and there is no reason to believe that malaria kills off a larger proportion of the inhabitants than previously. Indeed, the Calcutta statistics of recent years tend to show the contrary. Hindus and Mahomedans suffer equally; but malaria is no respecter of persons, at any rate in India, although females seem to die from this disease in greater proportion than males. The present epidemic of autumn fever extends all over the central parts of the country and Bombay. It is more widespread than has been known for several years and its effects are felt both in towns and villages. The area affected is so large that but little can be done to check the outbreak, though the distribution of quinine is proceeding as rapidly as possible. The conditions of rural life especially are such that the application of scientific methods is beset with many difficulties.

Plague.

Except in the Bombay Presidency plague does not so far show any signs of recrudescence. In the Punjab, which has suffered so severely in the last few years, the Ludhiana and Ferozepore districts report a certain number of deaths every week and the disease has a slight hold still upon the Canal colonies and in Patiala State, but the weekly mortality is small. In the United Provinces there are a few cases in the Gorakhpur division, but the latest returns show only 16 deaths in the week. In Bengal out of 72 deaths 49 occurred in the Monghyr district. Plague has reappeared in the Berars, Amraoti town and district being most affected; and in the Hyderabad and Mysore States the mortality is what might be expected at this season of the year. On the being the cash lying at the bank, and has also transferred £500 Consols, invested capital.

WE regret to announce the death, on Nov. 27th, of Dr. William Alfred Elliston of Felixstowe, in his sixty-ninth year. Dr. Elliston was the President of the British Medical Association in 1900 and the father of Mr. Guy Elliston, the general secretary of the British Medical Association. We hope to publish some notes of his career.

A TELEGRAM from the Acting Governor of Mauritius, received at the Colonial Office on Nov. 27th, states that for the week ending Nov. 26th there were 11 cases of plague and 8 deaths from the disease.

MOTORING NOTES.

By C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

THE question of insurance of a motor car, especially for one used daily, as medical men use their automobiles, is a most important one, and as since referring to the matter in a recent article I have had a good many letters from professional colleagues, I thought that perhaps the profession might like particulars as to some of the chief offices that undertake this class of risk, the salient features of their policies, and the points to which to pay attention when contemplating such an insurance.

I think it may be taken as beyond doubt that all who own or drive motors should be covered against any sum they may become legally liable to pay as damages and costs for injury to any person or persons, or for damage to property caused by the car while in charge of either the owner or his driver. However carefully a man drives someone may fall in front of the car, and then, whether the driver is to blame or not, even whether the person is actually injured or not, there is the possibility of an action for compensation. If these risks are covered the insurance companies defend the action, or, what is more often the case, they compensate the alleged injured party, save all worry, and relieve the insured of all responsibility. The one point to make certain about is that the policy covers all likely risks. A policy for, say, £100 third party risks, is of little value, for if someone should unfortunately be injured or think himself damaged a sympathetic jury might give him £500 damages, and then the insured would have himself to pay the extra £400, and in addition be uncovered as to third party risks for the rest of the term of his policy. A good many take out an insurance and get a special discount by carrying themselves the first £5, or £10, or even £25, of each claim, the discount being as much as 40 per cent. in the last-named instance with the Motor Union Insurance Co., but it appears to me not a good plan. Only recently I read in the *Autocar* a letter from a gentleman whose policy covers all liability with the exception of the first £5 of any claim; he had an accident consisting of damage to car £6 10*s*. and injury to a wall £3; the company merely allowed £1 10*s*. for the car damage and nothing towards the other claim. I understand that this is perfectly correct, and also that under such a policy if a car slightly injured, say, ten people and four dogs, and if the 14 claims were each for less than £5, the insured would himself have to pay each claim and the company would not be liable for any of them. The conclusion seems that if it is worth while to insure then it is as well to cover all liability.

Some companies, such as the Commercial Union, United Legal Indemnity Insurance Society, the Motor Union Insurance Co., D. A. Kinlock's Lloyd's Policy, and the Car and General Insurance Corporation, Limited, now issue, either alone or combined with their composite policies, protection against all claims for personal injury and damage to property up to an unlimited amount and without any limit as to the number of accidents. As while on a professional round one frequently has to enter private roads, such as a private park or a drive up to the patient's house, and as then damage might be done to a gate or fence, I think it would be as well to insist that third party risks should cover damage though done on a private road, if the same has to be entered for the purpose of paying a professional call. I notice that the Commercial Union Company especially state: "*Accidents to car are not limited to a public thoroughfare.*"

Personally I always drive myself, and nearly all the companies, I notice, allow a 5 per cent. reduction in the premium if the car is driven only by the owner, which is, I think, wise, as the owner is certainly more careful of his property than a paid driver would be. I remember last year having to go to Gravesend to conduct some St. John Ambulance examinations; a fog came on and I took over four hours in covering the nine miles to my home, and next day I heard a colleague's chauffeur remarking how, if he had been the driver, no matter how dense the fog might have been he would have done it in not much over the hour. His speech made me very glad that I was my own driver and also made me comprehend why the insurance companies allow a reduction if the owner is his own driver.

The question of covering damage to one's own car is a debateable one. If a driver is employed it is probably as well to cover this risk; if the owner is his own chauffeur he may like to take these risks himself. I now do so. Still, "pride may have a fall," and some day I may regret my saving of a few pounds a year needed to cover this extra risk. I was sorry that I had not done so some six years ago, when my hub brake drum fell off on Hog's Trough Hill, Brasted, and my but two-year-old Benz, which cost £260, became a wreck that merely fetched £30, so when the new car arrived I did not refuse to see the soft-spoken gentleman who called to expatiate on the advantages of insurance; in fact, I listened, was convinced, and insured. One day an unminded coal-cart horse elected to have a free motor drive; he decided on my little two-seater and jumped in alongside of me. I like both the mechanically propelled and the vehicles drawn by living animals, but I rather bar the two combined, so with a little effort and a big jump over the steering column and radiators I retired and left the quadruped in possession. Alas, the animal had a trade jealousy of the horseless carriage, and anyway the car was not built for the job, and the axle and body suffered. Though I was not to blame—in fact, the owners of the coal-cart were fined for leaving their horses unattended—still the insurance company kept me waiting some time before they sanctioned the repairs needed, and then were not over-generous. I had a trouble to get a new front axle, as their repairer wished to straighten the old one which had bent when the horse posed himself on it. Insurance companies are now, I believe, more generous, and the companies I name I have heard are most fair and anxious to satisfy their customers. All the companies mentioned here permit small repairs up to £5 to be executed without waiting for the company's consent; and, what is most important, a replacement value of the car can be agreed upon by arrangement at the time of effecting the insurance. This latter is of consequence, as otherwise if the car is totally destroyed by accident or fire the company would only pay the market value, which in the present state of the motor trade may be very different to the replacement value.

Most policies now include damage to lamps and tyres when the car is also damaged, though the majority have a limit of £5 for each lamp and only pay the cost of repairing rubber tyres where the damage is directly and immediately due to the accident for which compensation is payable, and they exempt superficial incisions.

For an additional premium certain of the companies undertake to provide the assured with a temporary car or to pay compensation at the rate of £10 a week during the repair of any damage to the car claimable under the insurance; others without extra premium agree to pay special compensation of £1 per day if repairs of insured damage to car are not completed within 20 working days from date of acceptance of estimate by the company, but I somehow think that they seldom have to pay under the latter clause. Still, with foreign cars there is always the possibility that great delay may occur in obtaining spare parts, but probably the insurance company would not accept an estimate until the repairer had the new parts in hand. I remember a friend who some two years ago cracked his water jacket and he was kept waiting over two months for a new cylinder cover. I myself only this year had to wait three weeks for a large crown wheel, but I am pretty positive that if I had been so insured I should not have been paid by the insurance company.

The United Legal Indemnity Insurance Company and the officer, said that Sydney's infant mortality-rate for the last two and a half years was only 91 per 1000. Already the city authorities had a system by which 65 per cent. of nursing mothers in the city and practically all the poor ones were visited by a lady inspector who gave advice as to the feeding and management of infants.

Friendly Societies.

Some time ago the New South Wales branch of the British Medical Association submitted a model agreement to the friendly societies in that State which contained a provision—

> That any person joining a lodge shall be deemed ineligible for any medical benefit from such lodge, if on joining he and his wife have a joint income of over £200 per annum, or at any time thereafter their joint income exceeds £300.

This has been submitted to the societies concerned and rejected, practically unanimously. At a meeting of the Friendly Societies' Association it was moved—

> That the British Medical Association be informed that this association will not agree to any model agreement containing a wage limit.

A subsequent motion desiring a conference was lost.

Public Health of Victoria.

The annual report of the Victorian Board of Public Health sets forth that a vigorous aggressive movement has been made against tuberculosis. With the extension of accommodation for consumptives the board has felt justified in enforcing the notification of cases. It is not claimed that this is entirely effective but the number of notifications is increasing. In 1904, 413 cases were reported and in 1907, 841. The mortality from tuberculosis is said to be falling steadily. Under the Milk and Dairy Supervision Act records are kept of 68,000 dairy cows. 287 cows have been discovered to be diseased and 126 have been destroyed.

Sydney Quarantine Station.

The Sydney quarantine station is situated just within the North Head at the entrance to the harbour. The suburb of Manly, which is one of Sydney's pleasure resorts and the home of surf-bathing, now runs up to within a mile or two of the quarantine area. It has been pointed out that the present site of the quarantine ground cuts off a large area that might be used as a picturesque pleasure reserve, and a movement is on foot to shift the quarantine buildings to some other part of the harbour. The question will, however, be one for the Commonwealth Parliament, as there is not likely to be any alteration made before the control of quarantine is handed over to the Federal authorities.

Oct. 20th.

Obituary.

RAHEEM MAHOMED BUKSH, M.R.C.S. ENG., L.S.A.

Raheem Mahomed Buksh, who died at The Hall, Balaam-street, Plaistow, on Nov. 15th, was at the time of his death honorary surgeon to the Plaistow Dispensary. He had previously been house surgeon and house physician at the London Hospital, where he was very well known to everyone and enjoyed general esteem and respect. After being house surgeon at the Poplar Hospital, where he went from the London Hospital, he settled at Plaistow, and in course of time obtained a considerable practice. Here he was helped by his deceased wife who had been a nurse at the London Hospital and whose kindness to the very poor was of the practical sort that comes from experience. The grateful appreciation of these unfortunate people of the efforts made in their behalf was evidently regarded by both husband and wife as a more than adequate return for their labours. For some time Mr. Buksh had been in indifferent health, though he had allowed but few even amongst his most intimate friends to be aware of it. Most fortunately he suffered little if at all from his condition, and his last days were cheered by the kindly attention of Dr. W. J. Hadley and his old and highly esteemed friend Mr. T. H. Openshaw. The interment took place at Brooklands on Nov. 20th in the Mahomedan section, the ceremony being attended by a number of his old fellow students and patients. He was reverently laid to rest by his Indian fellow countrymen residing in London.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Alonzo B. Ball, formerly professor of medicine in the College of Physicians and Surgeons, New York.—Dr. Turner Anderson, professor of midwifery and gynæcology in the University of Louisville.—Dr. San Martin y Satrústegui, professor of clinical surgery in the University of Madrid.—Dr. Benjamin Anger, formerly surgeon to the Paris Hospitals.—Dr. J. B. McGaughey of Winona, one of the most popular practitioners in the State of Minnesota. In early life he fought on the side of the Union Army in which he attained commissioned rank. While outside the lines at Stevenson, Alabama, caring for his wounded colonel, he was captured by the enemy and was for a time in Libby prison. After the war he studied medicine and graduated at the University of Michigan. He was one of the two delegates from Minnesota to the last Convention of the American Medical Association, and he served for many years as a member of the State Board of Medical Examiners.—Dr. Albert Carrier, formerly physician to the Lyons hospitals—Dr. Félizet, formerly surgeon to the Paris hospitals—Dr. Paul Vidal, formerly surgeon to the Marseilles hospitals.—Dr. Kiutsch, *privat-docent* of children's diseases in the University of Moscow.—Dr. Vincenzo Brigidi, formerly professor of pathology and anatomy in Genoa.

Medical News.

TRINITY COLLEGE, DUBLIN.—At the Final Medical Examination, Part II., held recently the following candidates were successful:—

> *Midwifery.*—Ralph T. St. J. Brooks, Frederick A. Anderson, Victor B. Kyle, Howard S. Millar, John D. Kernan, Harold S. Sugars, William Knapp, Edwin B. Bate, Charles B. Jones, and James D. Murphy.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Georg Jürgens, assistant physician in the second medical clinic of the Charité, has been granted the title of Professor. Dr. Gustav Schütz, teacher of mechanical therapeutics, has also been given the position of Professor.—*Cologne (Academy of Practical Medicine):* Dr. Ferdinand Zinsser, chief medical officer of the City Hospital at Lindenberg, has been appointed Professor of Dermatology; Dr. August Prochsting, chief medical officer of the City Eye Hospital, Professor of Ophthalmology; and Dr. Carl Cramer, chief medical officer of the Bürger Hospital, Professor of Orthopædic Surgery.—*Gottingen:* Dr. Eichelberg has been recognised as *privat-docent* of Mental Diseases.—*Kiel:* An orthopædic polyclinic or out-patient department has been attached to the University Surgical Clinic.—*Nantes:* Dr. Mirallié has been transferred at his own request from the chair of Forensic Medicine to that of Pathology.—*Rouen:* Dr. Dévé has been appointed to the chair of Internal Pathology in succession to Dr. Brunon.—*Vienna:* Dr. Ferdinand Hochstetter of Innsbruck has been appointed to the chair of anatomy vacated by the death of Dr. Toldt. Surgeon-General Florian Kratschmer, Ober-Sanitätsrat, has been knighted.

THE IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.—This association held its autumn dinner on Nov. 24th, at the Hotel Cecil, Strand, London, under the chairmanship of the President, Surgeon-General Sir Charles MacDonagh Cuffe. The toast of "Our Defenders," proposed by Judge Rentoul, was responded to by Dr. Samuel Browne, late Surgeon, R.N. Major V. H. W. Davoren, R.A.M.C., who also replied, said that Mr. Haldane had provided them with a scheme for a large territorial force which it was hoped would be carried out completely when the country understood that it was the duty of every able-bodied man to assist in the national defence. He declared that under the able directorship of the present officer in command the Army Medical Service was in a more efficient state than at any time in its previous history. Dr. J. A. Macdonald submitted the toast of "The Guests" and said that the name of one of them, Sir Robert Hart, would stand as one of the foremost of that honoured band of Irishmen which had rendered the name of Britain the foremost in all matters of progress, humanity, and religion. Sir Robert Hart, in his reply, described the difficulties in the way of progress in medical science in China but gave some

Fire, explosion, &c.—Loss of or damage to car [including tyres, lamps, and accessories whilst actually on insured car] by fire, explosion, self-ignition, or lightning, anywhere in the United Kingdom, will be covered up to full value at the time of fire.

Theft.—Loss of car by theft [excluding accessories, unless car stolen at same time] will be covered anywhere in the United Kingdom up to full value at time of theft.

The h.p. is the lower of the two stated by the maker.	6-h.p.	8-h.p.	10-h.p.	12-h.p.	16-h.p.	20-h.p.
	£ s.	£ s.	£ s.	£ s.	£ s.	£ s.
Full indemnity (except mechanical breakdowns, excess £10)	8 10	11 0	12 10	13 10	16 0	19 0
Full indemnity. Excess first £5 each claim under each section (except mechanical breakdowns, excess £15)...	7 0	9 10	11 0	12 0	14 10	17 10
Full indemnity. Excess first £10 each claim under each section (except mechanical breakdowns, excess £20)...	6 0	8 10	9 10	10 10	13 0	16 0
Full indemnity. Excess first £25 each claim under each section (except mechanical breakdowns, excess £35)...	4 0	6 0	7 0	8 0	10 0	12 0

This company also issues a policy excluding mechanical breakdowns at a somewhat lower premium, about £1 in each case.

A special "Lloyd's" policy is issued by Mr. D. A. Kinlock (Messrs. Leslie and Godwin) of 52, Cornhill, London, E.C. This covers all third-party claims, as well as damage to insured car, including lamps and tyres, also loss by fire or theft. An important feature claimed is that the policy contains a clause to the effect that the value of a sum to be fixed at the time of effecting the insurance is admitted for all purposes of loss or damage, and so in the event of total destruction by fire or accident the owner obtains a replacement sum instead of the market value of the property. Mr. Kinlock does not issue a scale of rates but treats each car upon its merits. I also understand that he allows a return of from 25 to 30 per cent. of the premium when no claim is made under the policy.

The Railway Passengers' Assurance Company of 64, Cornhill, London, E.C., issue policies giving benefits, as shown in the table given below:—

Benefits secured.	£10 10*s.* premium insures up to the undermentioned amounts.	£16 premium insures up to the undermentioned amounts.	£18 10*s.* premium insures up to the undermentioned amounts.	£20 5*s.* premium insures up to the undermentioned amounts.
1. Indemnity against legal claims for damage to persons and property.	£100 for one accident with a limit of £300 in one year.	£200 for one accident, with a limit of £600 in one year.	£250 for one accident, with a limit of £750 in one year.	£300 for one accident, with a limit of £900 in one year.
2. Indemnity against damage to car (lamps and tyres excepted) caused by collision or external and accidental means (other than explosion or self ignition or combustion), not occasioned by any known defect in the car. [N.B.—The first £2 of any damage is borne by the assured.]	£50 for one accident, with a limit of £150 in one year.	£100 for one accident, with a limit of £300 in one year.	£150 for one accident, with a limit of £450 in one year.	£200 for one accident; with a limit of £600 in one year.
3. Indemnity against damage to car caused by explosion or self-ignition or combustion not occasioned by any known defect in the car.	£100.	£150.	£200.	£250.
4. Indemnity against loss of car by theft or burglary or damage to car caused by attempted theft or burglary.	£100.	£150.	£200.	£250.
5. Insurance of paid driver...	Not provided for in above premium (but may be at an extra charge).	£100 for death. £1 a week during total disablement. (Limit 26 weeks.)	£100 for death. £1 a week during total disablement. (Limit 26 weeks.)	£100 for death. £1 a week during total disablement. (Limit 26 weeks.)

ROYAL SOCIETY OF MEDICINE.

DEBATE ON HEREDITY, WITH SPECIAL REFERENCE TO CANCER, TUBERCULOSIS, AND DISEASE OF THE NERVOUS SYSTEM.—(*Continued from p. 1627.*)

Mr. H. T. BUTLIN reopened the discussion, directing his attention chiefly towards the question of cancer. He said that the labours of the Imperial Cancer Research Committee had shown that certain animals—for instance, certain mice—showed a susceptibility to cancer, while other mice were comparatively immune. And it was natural to infer that if such were true of mice it would be true also of men. And that susceptibility had been shown to be really born in the animal. With regard to heredity, on the one hand it exercised a far-reaching influence, and yet there were curious limitations. For instance, it was said by those who held that cancer was due to heredity that collateral branches must be shut out and that one must not talk of the heredity of cancer skipping a generation. He gave an instance of a man who had a peculiar instinct which enabled him to assess readily the value of old curios and it was said by his friends that he must be a Jew. But he said he was not, but when inquiry was made it was discovered that one of his ancestors married a Jewess, and he felt sure that that strain was in the blood. The susceptibility to hay fever seemed also to be inherited, but some members of a family were susceptible to hay fever while the others were not. The same family predisposition and limitation were seen in cases of exostosis. It was generally accepted that certain features could be inherited, such as the shape of the nose, the colour of the eyes and hair, the qualities of meanness and cowardice on the one hand, and courage and generosity on the other. It was also admitted that the strength or weakness of certain parts could be inherited, and so could abnormalities. Many believed also that the tendency to gout could be similarly transmitted. It had been said that those who believed in heredity could not support their side by figures, but at all events it was supported by logic, and there was also such evidence as was afforded by Dr. Bashford's figures. The arguments against heredity were put forward by his colleague at St. Bartholomew's, Mr. Cripps, 30 years ago. The arguments came to this: that one must exclude in the evidence in favour of inheritance those cases in which the disease had skipped a generation, and also that evidence which depended upon the number of collateral relatives who suffered from the disease, and one must exclude those cases in which the disease was not of the same variety in all the members of the family. But those who believed in heredity did not feel disposed to accept those restrictions. Another objection made was that there was no regular proportion of the number of those who suffered from cancer in the susceptible families and that there was not enough cancer shown in the families which were regarded as susceptible. He would take the instance of a man with epithelioma on the edge of his tongue. The man said he scratched his tongue with a carious tooth weeks or months previously. Mr. Butlin found that in front of his tongue there were leucoplakia and chronic superficial glossitis and there was a clear history of syphilis long ago. The man was over 40 years of age. After thinking out the etiology of the disease he said it was, first, that he had injured his tongue by his carious tooth; secondly, that he had on his tongue for a considerable time officer, said that Sydney's infant mortality-rate for the last two and a half years was only 91 per 1000. Already the city authorities had a system by which 65 per cent. of nursing mothers in the city and practically all the poor ones were visited by a lady inspector who gave advice as to the feeding and management of infants.

Friendly Societies.

Some time ago the New South Wales branch of the British Medical Association submitted a model agreement to the friendly societies in that State which contained a provision—

> That any person joining a lodge shall be deemed ineligible for any medical benefit from such lodge, if on joining he and his wife have a joint income of over £200 per annum, or at any time thereafter their joint income exceeds £300.

This has been submitted to the societies concerned and rejected, practically unanimously. At a meeting of the Friendly Societies' Association it was moved—

> That the British Medical Association be informed that this association will not agree to any model agreement containing a wage limit.

A subsequent motion desiring a conference was lost.

Public Health of Victoria.

The annual report of the Victorian Board of Public Health sets forth that a vigorous aggressive movement has been made against tuberculosis. With the extension of accommodation for consumptives the board has felt justified in enforcing the notification of cases. It is not claimed that this is entirely effective but the number of notifications is increasing. In 1904, 413 cases were reported and in 1907, 841. The mortality from tuberculosis is said to be falling steadily. Under the Milk and Dairy Supervision Act records are kept of 68,000 dairy cows. 287 cows have been discovered to be diseased and 126 have been destroyed.

Sydney Quarantine Station.

The Sydney quarantine station is situated just within the North Head at the entrance to the harbour. The suburb of Manly, which is one of Sydney's pleasure resorts and the home of surf-bathing, now runs up to within a mile or two of the quarantine area. It has been pointed out that the present site of the quarantine ground cuts off a large area that might be used as a picturesque pleasure reserve, and a movement is on foot to shift the quarantine buildings to some other part of the harbour. The question will, however, be one for the Commonwealth Parliament, as there is not likely to be any alteration made before the control of quarantine is handed over to the Federal authorities.

Oct. 20th.

Obituary.

RAHEEM MAHOMED BUKSH, M.R.C.S. ENG., L.S.A.

Raheem Mahomed Buksh, who died at The Hall, Balaam-street, Plaistow, on Nov. 15th, was at the time of his death honorary surgeon to the Plaistow Dispensary. He had previously been house surgeon and house physician at the London Hospital, where he was very well known to everyone and enjoyed general esteem and respect. After being house surgeon at the Poplar Hospital, where he went from the London Hospital, he settled at Plaistow, and in course of time obtained a considerable practice. Here he was helped by his deceased wife who had been a nurse at the London Hospital and whose kindness to the very poor was of the practical sort that comes from experience. The grateful appreciation of these unfortunate people of the efforts made in their behalf was evidently regarded by both husband and wife as a more than adequate return for their labours. For some time Mr. Buksh had been in indifferent health, though he had allowed but few even amongst his most intimate friends to be aware of it. Most fortunately he suffered little if at all from his condition, and his last days were cheered by the kindly attention of Dr. W. J. Hadley and his old and highly esteemed friend Mr. T. H. Openshaw. The interment took place at Brooklands on Nov. 20th in the Mahomedan section, the ceremony being attended by a number of his old fellow students and patients. He was reverently laid to rest by his Indian fellow countrymen residing in London.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Alonzo B. Ball, formerly professor of medicine in the College of Physicians and Surgeons, New York.—Dr. Turner Anderson, professor of midwifery and gynæcology in the University of Louisville.—Dr. San Martin y Satrústegui, professor of clinical surgery in the University of Madrid.—Dr. Benjamin Anger, formerly surgeon to the Paris Hospitals.—Dr. J. B. McGaughey of Winona, one of the most popular practitioners in the State of Minnesota. In early life he fought on the side of the Union Army in which he attained commissioned rank. While outside the lines at Stevenson, Alabama, caring for his wounded colonel, he was captured by the enemy and was for a time in Libby prison. After the war he studied medicine and graduated at the University of Michigan. He was one of the two delegates from Minnesota to the last Convention of the American Medical Association, and he served for many years as a member of the State Board of Medical Examiners.—Dr. Albert Carrier, formerly physician to the Lyons hospitals. —Dr. Félizet, formerly surgeon to the Paris hospitals—Dr. Paul Vidal, formerly surgeon to the Marseilles hospitals. —Dr. Kiutsch, *privat-docent* of children's diseases in the University of Moscow.—Dr. Vincenzo Brigidi, formerly professor of pathology and anatomy in Genoa.

Medical News.

TRINITY COLLEGE, DUBLIN.—At the Final Medical Examination, Part II., held recently the following candidates were successful:—

Midwifery.—Ralph T. St. J. Brooks, Frederick A. Anderson, Victor B. Kyle, Howard S. Millar, John D. Kernan, Harold S. Sugars, William Knapp, Edwin B. Bate, Charles B. Jones, and James D. Murphy.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Georg Jürgens, assistant physician in the second medical clinic of the Charité, has been granted the title of Professor. Dr. Gustav Schütz, teacher of mechanical therapeutics, has also been given the position of Professor.—*Cologne (Academy of Practical Medicine):* Dr. Ferdinand Zinsser, chief medical officer of the City Hospital at Lindenberg, has been appointed Professor of Dermatology; Dr. August Prochsting, chief medical officer of the City Eye Hospital, Professor of Ophthalmology; and Dr. Carl Cramer, chief medical officer of the Bürger Hospital, Professor of Orthopædic Surgery.—*Gottingen:* Dr. Eichelberg has been recognised as *privat-docent* of Mental Diseases.—*Kiel:* An orthopædic polyclinic or out-patient department has been attached to the University Surgical Clinic.—*Nantes:* Dr. Mirallié has been transferred at his own request from the chair of Forensic Médicine to that of Pathology.—*Rouen:* Dr. Dévé has been appointed to the chair of Internal Pathology in succession to Dr. Brunon.—*Vienna:* Dr. Ferdinand Hochstetter of Innsbruck has been appointed to the chair of anatomy vacated by the death of Dr. Toldt. Surgeon-General Florian Kratschmer, Ober-Sanitätsrat, has been knighted.

THE IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.—This association held its autumn dinner on Nov. 24th, at the Hotel Cecil, Strand, London, under the chairmanship of the President, Surgeon-General Sir Charles MacDonagh Cuffe. The toast of "Our Defenders," proposed by Judge Rentoul, was responded to by Dr. Samuel Browne, late Surgeon, R.N. Major V. H. W. Davoren, R.A.M.C., who also replied, said that Mr. Haldane had provided them with a scheme for a large territorial force which it was hoped would be carried out completely when the country understood that it was the duty of every able-bodied man to assist in the national defence. He declared that under the able directorship of the present officer in command the Army Medical Service was in a more efficient state than at any time in its previous history. Dr. J. A. Macdonald submitted the toast of "The Guests" and said that the name of one of them, Sir Robert Hart, would stand as one of the foremost of that honoured band of Irishmen which had rendered the name of Britain the foremost in all matters of progress, humanity, and religion. Sir Robert Hart, in his reply, described the difficulties in the way of progress in medical science in China but gave some

THE LANCET, *SATURDAY*, Dec. 4th, 1830.

PROPOSED IMPROVEMENT IN THE CONSTRUCTION OF SPECTACLES.

By MARTIN EVANS, *M.D.*, *Teignmouth.*

MANY of your readers may be inclined to suppose that the subject of the present letter is misplaced, when inserted in the columns of your invaluable Journal. However, I am disposed to look upon any information which tends to remedy a defect in the organs of our most useful sense, the eyes, as perfectly adapted to them.

For some time past, I have been in the habit of using the doubly-concave eye-glass, commonly employed by young people, and have found that its utility may be very much, indeed wonderfully increased, by fixing it in a particular direction in relation to the eye. The statement for procedure in the experiment may appear obscure without the assistance of a diagram, but I shall endeavour to make myself as intelligible as the nature of the subject admits. That part of the glass which rests at the inner canthus should be fixed as a centre, whilst the part towards the external canthus is directed *forwards* to a degree which varies in different persons. When it reaches this point or focus, the object viewed appears extremely clear, so much so indeed as to justify an assertion of increase in a double ratio. Persons who do not require the aid of glasses cannot appreciate this improvement. Those only whose vision is so far impaired as to need such artificial contrivance will pronounce on its application. My experiments on the doubly-convex glasses of old people, have not been sufficient to bear me out in extending the principle to them; neither have I as yet arrived at a satisfactory rationale of the process; some of your readers, therefore, may be ingenious enough to do so. From the knowledge of this circumstance, I venture to suggest to Opticians a practical improvement in the construction of spectacles. It is the following:—Let the space between the lenses, or that part which rests on the ossa nasi, be formed with a *pretty stiff* horizontal joint in the centre, in order that an obtuse angle could be formed when necessary, the vertex represented by the joint, the sides by those parts of the spectacles which surround the lenses and directed *forwards* to a certain extent as above mentioned. This shape, although at present appearing unhandsome, would by time, and its utility, be reconcilable to our ideas of beauty in figure.

Teignmouth, Devonshire, October 25, 1830.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7591 births and 4847 deaths were registered during the week ending Nov. 28th. The annual rate of mortality in these towns, which had been equal to 15·9 and 15·6 per 1000 in the two preceding weeks, was again 15·6 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these towns averaged 14·6 per 1000, and in London the mean rate during the same period did not exceed 14·0. The lowest annual death-rates in these towns last week were 4·7 in East Ham, 5·8 in Burton-on-Trent, 5·9 in Coventry, and 6·2 in Hornsey; the rates in the other towns ranged upwards, however, to 23·4 in Stockport, 23·5 in Stockton-on-Tees and Walsall, 25·4 in Rotherham, and 26·2 in Middlesbrough. In London the death-rate last week was equal to 15·8, and was higher than in any week since the beginning of May last. The 4847 deaths from all causes in the 76 towns were within four of the number returned in the previous week, and included 407 which were referred to the principal epidemic diseases, showing a further slight decline from the numbers in recent weeks; of these 407 deaths, 140 resulted from measles, 102 from diarrhœa, 66 from diphtheria, 41 from "fever," 30 from whooping-cough, and 28 from scarlet fever, but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 1·3 per 1000, against 1·4 in each of the two previous weeks; the rate from these diseases was also equal to 1·3 per 1000 in London. No death from any of these epidemic diseases was registered last week in Burnley, Swansea, Northampton, Hornsey, Reading, or in five other smaller towns; the annual death-rate therefrom, however, ranged upwards in the other towns to 3·6 in Stockport, 3·7 in Warrington, 5·6 in Leicester, 7·4 in Rotherham, and 7·6 in Middlesbrough. The fatal cases of measles in the 76 towns, which had steadily increased in the nine preceding weeks from 31 to 126, further rose to 140 in the week under notice; they caused annual death-rates equal to 1·5 in Oldham, 2·2 in Huddersfield, 2·5 in Stockport, 4·6 in Leicester, and 4·9 in Rotherham. The 102 deaths attributed to diarrhœa during last week showed a further decline of 37 from the numbers in recent weeks, and were fewer than in any week since the beginning of July last; the highest annual death-rates from this cause during the week were 1·5 in West Bromwich, Warrington, and Oldham, 1·6 in Rotherham, and 1·9 in Tynemouth. The 66 deaths from diphtheria showed an increase of ten upon those returned in the previous week; they included 37 in London and its suburban districts, three in Birmingham, two in Liverpool, four in Manchester and Salford, two in Sheffield, three in Hull, and two in Newport. The 41 deaths referred to "fever" during the week were within one of the number in the previous week, and included 15 in London and its suburban districts, four in Manchester and Salford, and two in Liverpool. The fatal cases both of whooping-cough and scarlet fever were below the average, and differed but slightly from recent weekly numbers; the two deaths from scarlet fever in Handsworth were equal to an annual rate of 1·5 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 3881 and 3809 at the end of the two preceding weeks, had risen again to 3831 on Saturday, Nov. 28th; the new cases of this disease admitted to these hospitals during the week under notice were 491, against 500 and 421 in the two preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily increased in the six preceding weeks from 159 to 334, declined to 318 in the week under notice, and were 112 below the corrected average number in the corresponding week of the five years 1903–07. The causes of 53, or 1·1 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were again duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 43 other smaller towns; the 53 uncertified causes of death in the 76 towns included, however, six in Liverpool, four in Birmingham, four in Sheffield, four in Preston, three in South Shields, three in Manchester, and three in West Bromwich.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 16·9 and 17·3 per 1000 in the two preceding weeks, declined again to 16·4 in the week ending Nov. 28th. During the first nine weeks of the current quarter the annual death-rate in these eight towns averaged 15·0 per 1000, and exceeded by 0·4 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 12·1 and 14·8 in Paisley and Perth, to 18·2 in Greenock and 18·4 in Aberdeen. The 577 deaths in the eight towns showed a decline of 33 from the number returned in the previous week, and included 57 which were referred to the principal epidemic diseases, against 68 and 62 in the two preceding weeks; of these 57 deaths, 25 resulted from diarrhœa, 16 from whooping-cough, nine from scarlet fever, five from diphtheria, and two from "fever," but not one either from measles or small-pox. These 57 deaths were equal to an annual rate of 1·6 per 1000, which exceeded by 0·3 the mean rate from the same diseases in the 76 English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had been 29, 24, and 22 in the three preceding weeks, rose again to 25 in the week under notice, and included her physical condition to the Board which will then consider whether a certificate should be granted to her; and (2) that a caution as to the health of intending candidates should be sent to all recognised training schools, recognised teachers, and approved midwives. It was agreed that Dr. G. E. Herman should be asked to inspect and to report on the maternity department of the Middlesex Hospital subject to the consent of the governing body of the hospital.

GLASGOW UNIVERSITY CLUB, LONDON.—This
nner on Nov. 27th, under the chair-
hibald Barr, in the Balmoral Hall of
W. The
has been
e club from 1901 to 1908, and has
at the club is in a position of great
prosperity with a membership of nearly 330. Professor Barr, after had been duly honoured, proposed d the Club." He mentioned that when he was appointed to the first professorship of engineering in the University of Glasgow it was his duty to deliver before the Senate an oration in Latin, which he described as the deadest of dead languages. This effort of his had a most remarkable result, for his eloquence so satisfied the craving of the Senate for Latin oratory that no one since had been asked to address them in that dead language. In the course of some humorous remarks on the origins of the learned professions he said that the beginning of medicine appeared to be wrapped in mystery, but he thought it would be agreed that the "medicine man" must have been developed at a late period because of the records of longevity that had come down to them from the earliest times. Dr. Guthrie Rankin then proposed the health of Dr. Hawthorne and spoke of his work for the club. Dr. Hawthorne, in reply, acknowledged the compliment paid to him and must have been much gratified at the enthusiastic reception accorded to his speech. Sir Donald MacAlister, in an eloquent and witty speech, proposed "The Guests," which was replied to by Professor James Little, who was followed by Sir William H. White, submitting the "Health of the Chairman," which was suitably acknowledged.

MIDDLESEX HOSPITAL.—A meeting of the court of governors was held on Nov. 26th; Mr. Andrew Clark presided. Major-General Lord Cheylesmore expressed the profound regret of the board at the death of the Earl of Derby, a true friend who had been for 17 or 18 years on the board. It was intended to erect a tablet to his memory in the chapel of the hospital and the secretary would be pleased to receive subscriptions for it. By the death of Sir Elliott Lees, too, they had lost a vice-president who never failed to display the keenest solicitude for the welfare of the hospital. To Mr. J. A. Mullens and his sons they gratefully acknowledged their indebtedness. It was unanimously recommended that the Earl of Derby, himself (Lord Cheylesmore), and the Hon. G. W. Spencer Lyttelton should be appointed vice-presidents of the hospital, and that Dr. William Duncan and Mr. William Hern should be elected consulting obstetric physician and consulting dental surgeon respectively. Mr. W. Salmon Nowell and Mr. H. Watson Turner had been appointed dental surgeon and assistant dental surgeon to fill vacancies. The value of the new observation wards had been proved during the past six months and lying-in wards had been successfully re-established. A contribution of £2500 towards their cost had been made by the trustees of the Zunz bequest. He regretted that their special appeal for funds for the Cancer Research Laboratories had not been very successful and the board urged that they should be helped in carrying on this great work, for which they required £2500 annually. The board was anxious that any interested should visit the hospital and see for themselves the work being done in the cancer wards and the Cancer Research Laboratories, which would create a wider sympathy and bring adequate financial support.

1st (Pembrokeshire) Volunteer Battalion, to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (to be supernumerary) (dated April 1st, 1908). 4th Battalion, The Duke of Edinburgh's (Wiltshire Regiment): Surgeon-Major Herbert Paget Tayler, from the 1st Wiltshire Volunteer Rifle Corps, to be Surgeon-Major, with precedence as in the Volunteer Force (dated April 1st, 1908). 6th Battalion, The Durham Light Infantry: Surgeon-Captain William Murray Mackay, from the 2nd Volunteer Battalion, to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

Royal Army Medical Corps.

Professor William Osler is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the South Midland Territorial Division (dated Sept. 21st, 1908).

For attachment to Units other than Medical Units: Surgeon-Captain Thomas Harper, from the 1st Ayrshire and Galloway Royal Garrison Artillery (Volunteers) to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Captain James Henry Hunter, from the 3rd Durham Royal Garrison Artillery (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Lieutenant Henry Goudie, from the 3rd Durham Royal Garrison Artillery (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Captain and Honorary Surgeon-Major Charles Sempill de Segundo, from the 20th Middlesex (Artists') Volunteer Rifle Corps, to be Captain with the honorary rank of Surgeon-Major, with precedence as in the Volunteer Force (dated April 1st, 1908). James Bertie Simpson (late Captain, 1st Sutherland Volunteer Rifle Corps), to be Captain (dated Sept. 1st, 1908). George Edward James Antoine Robinson, to be Lieutenant (dated Oct. 8th, 1908). Samuel Maclean (late Surgeon-Lieutenant, 1st (Cumberland) Volunteer Battalion, The Border Regiment), to be Lieutenant (dated Oct. 19th, 1908).

1st East Anglian Field Ambulance: Gerald Moore Hetherington to be Lieutenant (dated June 23rd, 1908).

3rd Lowland Field Ambulance: The following announcement is substituted for that which appeared in the *London Gazette* of Sept. 15th, 1908:—The undermentioned officers, from the 1st Edinburgh (City) Royal Garrison Artillery (Volunteers) are appointed, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain Alexander Morrison McIntosh to be Captain. Surgeon-Lieutenant James Hunter Harvey Pirie to be Lieutenant.

3rd Welsh Field Ambulance: Ernest Brice to be Lieutenant (dated May 20th, 1908).

3rd Wessex Field Ambulance: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel Henry Darville Brook, from the 20th Middlesex (Artists') Volunteer Rifle Corps, to be Major with the honorary rank of Surgeon-Lieutenant-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908).

2nd London General Hospital: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Clement Godson, from the 18th Middlesex Volunteer Rifle Corps to be Lieutenant-Colonel with the honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908).

3rd London General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated Dec. 2nd, 1908):—To be Lieutenant-Colonels: James Kingston Fowler, Rickman John Godlee, Sir Thomas Barlow, Bart., K.C.V.O., and Charles Robert Bell Keetley. To be Majors: Sidney Philip Phillips, Augustus Joseph Pepper, William Pasteur, Alfred Pearce Gould, John Rose Bradford, Arthur William Mayo Robson, Arthur Pearson Luff, and Arthur Edward James Barker. To be Captains:—Sidney Harris Cox Martin, Bilton Pollard, Walter Essex Wynter, James Ernest Lane, Arthur Francis Voelcker, John Bland-Sutton, Henry Albert Caley, Raymond Johnson, James Samuel Risien Russell, John Murray, Frank Joseph Wethered, Horace Stansfield Collier, Harold Batty Shaw, Thomas Herbert Kellock, Frederick John Poynton, Vincent Warren Low, Wilfrid Harris, William Sampson Handley, Sir John Francis Harpin Broadbent, Bart., and Rupert Thomas Hampden Bucknall.

4th London General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated Dec. 2nd, 1908):—To be Lieutenant-Colonels: Francis de Havilland Hall, Albert Boyce Barrow, Nestor Isidore Charles Tirard, and Clinton Thomas Dent. To be Majors: William Murrell, Sir William Watson Cheyne, Bart., C.B., Norman Dalton, George Robertson Turner, Sir Hugh Reeve Beevor, Bart., Stanley Boyd, Richard Grainger Hebb, and Alfred Herbert Tubby. To be Captains: Frederick Walker Mott, Walter George Spencer, William Aldren Turner, Albert Carless, James Galloway, Frederic Francis Burghard, Alfred Milne Gossage, Herbert Furnivall Waterhouse, Cyril Ogle, Frederick Charles Wallis, Raymond Henry Payne Crawfurd, Charles Gibbs, Arthur Latham, William Turner, William Hunter, Francis Jaffrey, William Cecil Bosanquet, Arthur Henry Evans, James Stansfield Collier, and Herbert Stringfellow Pendlebury.

Sanitary Service: George Reid to be Major (dated August 10th, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery: 1st Devonshire: Surgeon-Lieutenant Arthur Goulston resigns his commission (dated April 1st, 1908). 1st Warwickshire: Surgeon-Captain George Haddow resigns his commission (dated March 31st, 1908).

Rifle: 1st (Pembrokeshire) Volunteer Battalion, The Welsh Regiment: Surgeon-Captain Percival A. Lloyd resigns his commission (dated April 1st, 1908).

Consequent on the disbandment of the *Army Medical* Reserve of Officers, as constituted by the Royal Warrant of 1888, the undermentioned officers cease to be officers therein:—Surgeon-Lieutenant-Colonels: Rowland H. Coombs, George S. Elliston, James K. Anderson, Peter B. Giles, Andrew Clark, William R. Smith, Duncan McFadyen, James Duncan, Thomas Fort, Henry W. King, Walter S. Cheyne, Edward J. Lloyd, Edward Williams, Samuel B. Mason, Robert R. Brown, Charles Arrol, William J. Naismith, D.S.O., Edmond W. Symes, Robert de la Poer Beresford, Robert B. Smith, Edward B. Reckitt, Augustus S. Daly, Alfred Chawner, Edmond J. Lawless, Robert L. Sparrow, Francis J. Walker, Arthur T. Wear, William Ferguson, John Adam, Edwin J. Hunter, Frederick K. Pigott, William M. Roocroft, Alexander D. Fraser, Clement Godson, Andrew A. Watson, Henry W. Roberts, William H. Packer, John J. de Z. Marshall, John P. Massingham, Arthur B. Wade, Frederick W. Gibbon, George M. Lowe, Thomas Philip, Charles N. Lee, James W. T. Gilbert, David Lennox, William Nettle, James Turton, Murdo Mackenzie, James Mill, George Hollies, Charles A. MacMunn, Charles Graham Grant, Thomas McC. Foley, Robert B. Graham, Walter C. James, Charles L. Fraser, Henry C. Lamport, and Joseph Adams. Surgeon-Majors: Andrew A. Abraham, John A. Jones, John W. Ellis, Evan Evans, Thomas F. Dewar, John V. W. Rutherford, Ernest W. Barnes, William A. Dingle, William B. Mackay, Andrew P. Arnold, Robert Stirling, William O. Evans, Richard J. Bryden, Richard R. Sleman, Philip B. Bentlif, Robert T. Meadows, Frederick V. Adams, Edward H. Moore, Richard J. M. Coffin, Stanley S. Hoyland, William Kinnear, Hugh R. Bramwell, James A. Rigby, Josiah T. Thomas, William L. Edwards, Henry J. Mackay, David Todd, Henry D. Brook, James H. G. Whiteford, William P. Whitcombe, Walter A. Atkinson, Robert Mitchell, Thomas E. Stuart, William B. Cockill, Casper R. Laurie, Henry T. Challis, Hugh Dickie, Atwood Thorne, Sydney A. M. Copeman, John H. Stacy, John M. Moir, Alexander B. Lyon, Campbell Boyd, James A. Clark, Thomas Holt, Robert E. Beveridge, John S. Mackay, Eustace M. Callender, James P. S. Ward, Robert T. Ferguson, Arthur L. Jones, Samuel J. J. Kirby, Arthur P. Nuttall, Arthur D. Ducat, Charles G. Maclagan, Arthur H. Vernon, David Smart, Bonner H. Mumby, William Richardson, Edgar W. Livesey, Lewis W. Pockett, George Melville, James Cameron, Richard H. Luce, William P. Peake, George G. Oakley, and William K. Clayton. Surgeon-Captains: Francis H. Thompson, Harry L. de Legh, John H. P. Graham, James P. Brown, Conrad T. Green, Henry Waite, Thomas Thompson, Thomas Kay, William H. Vickery, Cecil A. Corke, James Taylor, John C. Wright, David R. Dobie, Edmond U. F. MacW. Bourke, Albert Henderson, Edmund E. Dyer, James S. Swain, Harry M. Brownfield, Hugh N. A. Taylor, Albert Ehrmann, Albert Hilton, Edward Gray, Francis A. Brooks, Neish P. Watt, Claud W. Marshall, Wilfred Curtis, George F. Whyte, without the express written consent of the Local Government Board." In his judgment these would work better into the fabric of the Bill.

Mr. *ADKINS said that the proposed clause was an extraordinary attack* on local self-government. The clause was framed in a way which showed distrust and dislike of county councils. He thought that the amend- President of the Local Government Board county councils as an unwarrantable inter-

Mr. *MUNRO FERGUSON* said that the difficulty in Scotland was to get efficient service and to get rid of the inefficient men. The second was the more difficult, because if they had an amiable person as a public servant he might have every vice but they could not get rid of him. If they gave a right of appeal he did not think it could be regarded as an attack on county councils, but he thought all local authorities should have a free hand in the matter of dismissals.

Mr. MASTERMAN said that the Local Government Board proposed to do for the county medical officers what it did in the case of all large municipalities. It proposed by *Order to prescribe the qualifications* and duties of the medical officer of health. The proposals of the Government were a *bonâ-fide* attempt to carry out what was demanded by social and sanitary reformers and to encourage a real and active county medical service.

Mr. BURNS, in the course of further discussion, said that the Local Government Board wanted to unify the public health service from the circumference to the centre. They wanted a general and broad uniformity of public health laws, regulations, and by-laws. It was impossible to prescribe all the duties of the officers in a schedule to the Bill. That would not allow the variation which was essential to public health, having regard to the constant advance of medical science.

Mr. RAINY thanked the Government on behalf of the medical profession for the medical clauses and declared that they would do much to promote good medical service in the country.

The amendment was then withdrawn and the amendments outlined by Mr. BURNS were agreed to.

The following provisions of the clause were then agreed to:—"(1) The Local Government Board may by Order prescribe the duties of medical officers of health appointed by a county council under section seventeen of the Local Government Act, 1888, whether before or after the passing of this Act. (2) The medical officer of health of a county council shall, for the purposes of his duties, have the same powers ed on a medical officer of health t. (3) The power of county council l section to make arrangements with respect to medical officers of health shall cease, without prejudice to any arrangement made previously to the date of the passing of this Act."

The second of the above subsections was an amendment proposed by Mr. BURNS.

Th "(1) The clerk of a rural district council shall officer of health of the county council a copy omplaint, or information, a copy of which it is the duty of the district council to forward to the county council Working Classes Act, ls). (2) The medical the medical officer of n his power to give, county council may is duties. (3) If the uncil fails to comply ole on summary conviction in respect of each offence to a fine not exceeding ten pounds."

These subsections were agreed to after "rural district council" in the first line of the first subsection had been substituted for "district council."

On the motion of Mr. THEODORE TAYLO was agreed shall arise council anc l to the Local Government under this Board, whose decision shall be final and binding."

The clause was then passed. The succeeding clause excludes Scotland from the operation of this part of the Bill, and it was agreed also to exclude the Administrative County of London. The clause then received the approval of the Committee and this concluded the consideration of Part III. of the Bill.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ARCHIBALD, W., M.D., Ch.B. Glasg., D.P.H. Cantab., has been appointed Medical Officer of Health of the Borough

BEIRNE, J. W., M.B., B.S. Irel., has been app under the Factory and Workshop Ac District of the county of Roscommon.

ENGLISH, E., M.D. Durh., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Swinton District of the county of York.

GRIFFITH, WILLIAM, M.B., Ch.B. Vict., has been appointed Casualty Medical Officer to St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.

GROSVENOR, WILSHAW WILLIAM, M.D. Dub., L.R.C.P. Lond., M.R.C.S., has been appointed Physician to the Gloucester General Infirmary and Eye Intstiution.

HAMILTON, W. CROSBIE, M.B., C.M. Edin., has been appointed Assistant Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

HAWKER, GEORGE POOLE DAVID, M.B., B.C. Cantab., has been appointed Honorary Assistant Surgeon to the West of England Eye Infirmary, Exeter.

KETTLE, E. H., M.B., B.S. Lond., has been appointed Assistant Path logist to the Cancer Hospital.

LANGMEAD, FREDERICK, M.D. Lond., M.R.C.P. Lond., has bee appoin eadnought" Hospita Greenv ry's Hospital.

LEWIS, A. appointed Certifyin Surgeo Act for the Rochfo District of the county of Essex.

LYNCH, M. E., L.R.C.P. & S. Irel., has been appointed Certifyin Surgeon under the Factory and Workshop Act for the Clashmo District of the county of Waterford.

MACPHERSON, J. T., M.D. Aberd., has been appointed Medical Offic to the Nicholls Hospital, Manchester.

MARTIN, ANTONY A., M.D. Lond., D.P.H., has been appointed Cert fying Surgeon under the Factory and Workshop Act to the Municip Borough and Rural District of Eastbourne.

ROBINSON, FRANK, M.D., D.P.H., has been appointed Medical Officer Health of the County of Cambridge.

SAWYER, JAMES E. H., M.D. Oxon, has been appointed Registrar of th 1st Southern General Hospital of the Royal Army Medical Corps o the Territorial Force.

SOLLY, REGINALD VAUGHAN, M.D., B.S. Lond., F.R.C.S. Eng., L.R.C.P Lond., has been re-elected Medical Registrar and Pathologist at th Royal Devon and Exeter Hospital, Exeter.

STRUTHERS, J. W., M.B., Ch.B., F.R.C.S. Edin., has been appointe Assistant Surgeon to the Royal Infirmary, Edinburgh.

THOMAS, W. J., M.R.C.S., L.R.C.P. Lond., D.P.H. Lond., has been ap pointed Clinical Assistant to St. John's Hospital for Diseases of th Skin, Leicester-square, W.C.

THORNTON, G., M.D. Edin., M.R.C.P. Lond., has been appointed Medica Superintendent of the General Hospital, Colombo, Ceylon.

TURTON, EDWARD, M.D. Vict., B.Sc., Ch.B. Edin., M.R.C.P. Lond., has been appointed Honorary Consulting Physician to the Hul Hospital for Women and Orthopædics.

WATERFIELD, WILLIAM HENRY, L.R.C.P., L.R.C.S., L.M. Irel., ha been appointed Medical Officer to the Workhouse, and District Medical Officer and Public Vaccinator by the Stonehouse (Devon) Board of Guardians.

YEATS, WILLIAM, M.D. Aberd., has been appointed Honorary Consulting Physician to the Nicholls Hospital, Manchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN, CITY (FEVER) HOSPITAL.—Resident Physician. Salary £100 per annum, with board.

BETHLEM HOSPITAL.—Two Resident House Physicians (unmarried) for six months. Salary at rate of £25 each per quarter, with apartments, board, and washing.

BETHNAL GREEN INFIRMARY.—Assistant Medical Officer. Salary at rate of £100 per annum, with apartments, board, and washing.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House Surgeon. Salary £70 per annum.

BIRMINGHAM, UNIVERSITY OF.—Lecturer in Physiology. Stipend £150 per annum.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—House Surgeon, unmarried. Salary £160, with rooms, coals, gas, and attendance.

BRISTOL ROYAL INFIRMARY.—Ophthalmic and Obstetric House Surgeon. Salary £75 per annum, with board, lodging, and washing. Also House Physician.

CAMBRIDGESHIRE, &c., ASYLUM, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and attendance.

CANCER HOSPITAL, Fulham-road, London, S.W.—Assistant Anæsthetist. Salary 25 guineas per annum.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon for six months. Salary £30, with board, residence, and laundry.

CEYLON, Medical Officer of Healtl

CHILDREN' Assistant Medical Officer. Salary £250 per annum. Also Assistant Medical Officer. Salary £150 per annum, both with board, lodging, and washing.

DUBLIN, DR. STEEVENS' HOSPITAL.—House Surgeon. Salary £100 per annum, with apartments, fire, and light.

DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, attendance, and washing.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Assistant Physician.

GREAT YARMOUTH HOSPITAL.—*House Surgeon*, unmarried. Salary £100 per annum, with board, lodging, and washing.

HAMPSTEAD GENERAL HOSPITAL.—Pathologist. Salary £100 per annum.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, and washing.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL.—*Honorary* Dental Surgeon.

HÔPITAL FRANÇAIS, 172, Shaftesbury-avenue, W.C.—Resident Medical Officer, unmarried. Salary £70 per annum, with full board.

HUDDERSFIELD INFIRMARY.—Senior *House Surgeon.* Salary £100 per annum, with rooms, board, washing, and attendance.

KENSINGTON GENERAL HOSPITAL, Earl's Court, *London*, S.W.—Resident Medical Officer. Salary £50 per annum, with board, washing, and residence.

KING EDWARD VII. HOSPITAL AND DISPENSARY FOR WINDSOR, ETON, AND DISTRICT.—House Surgeon, unmarried. Salary £110 per annum, with residenc forth, near

LEEDS TUBERCULOSIS Selby.—Resident Me ry at rate of £100 per annum, witl riod, for six

LINCOLN COUNTY HOSPITAL.— months. Salary £30, with board, residence, and washing.

Metropolitan Asylums Board to provide the accommodation for them. His statements are indeed not upheld by the investigations made by the Lunacy Commissioners on this very point in 1905. In that year the medical superintendents of county asylums were asked to report to the Lunacy Commissioners the number of senile cases in their asylums they thought could be suitably cared for in the workhouses. Two superintendents of London county asylums are quoted as answering the question. One, Dr. R. Jones of Claybury, replied that *all* the cases sent there could only be fitly treated in an asylum where there was a large and competent staff. Dr. W. J. Seward of Colney Hatch said that 32 of the 49 sent there might have been treated in a *special* ward of a workhouse infirmary, but it was doubtful if *any* could have been suitably cared for in an ordinary infirmary ward.

The Infirmary Medical Superintendents' Society feels that the public should know the difficulties which arise in practice in dealing with these senile cases owing to the want of provision of proper accommodation for them. It feels, also, that the only satisfactory solution will be for individual boards of guardians to provide the special accommodation required in the workhouse or infirmary and to arrange for the certification of all alleged lunatics admitted to the workhouse to be placed in the hands of the medical officer who alone is in a position to sift the cases properly and decide which should go to the county asylums and which should be detained in special wards in the workhouse or in the workhouse asylums of the Metropolitan Asylums Board.

I am, Sir, yours faithfully,

C. T. PARSONS,

Honorary Secretary, Infirmary Medical Superintendents' Society.

Fulham Infirmary, Hammersmith, W., Nov. 30th, 1908.

RECENT OUTBREAKS OF PLAGUE IN LIVERPOOL AND GLASGOW.

To the Editor of THE LANCET.

SIR,—It is the common fate of the medical man who first suggests the probability of plague in a community to be voted a public nuisance who ought to be chloroformed beyond the final stage of safe anæsthesia, for plague means so much to the mercantile and maritime interests of the city or town in which it may appear. In spite of this fate staring me in the face I submit that the chief aim of a physician ought to be the preservation of the health of a community and its wealth ought to be to him a secondary consideration. As a matter of fact, the one is bound up with the other, for in protecting and conserving the health of the citizen we are ultimately protecting and conserving his mercantile and maritime interests. If the infection in the recent three cases in Liverpool had been traced to a vessel that had arrived in the Mersey from a port in which plague was at present prevalent this letter would not have been written, but as the barge on which the first patient sickened did not go beyond the limits of the Mersey and was solely engaged in coaling coasting vessels, I would suggest that the origin of the infection should be sought within the gates of the city as well as at its portals, and every medical man as well as the port sanitary authorities should be on the alert for plague. In support of my suggestion let me briefly emphasise the connecting links between the five outbreaks of plague in Glasgow and Liverpool during the past eight years.

In August, 1900, plague appeared in Glasgow for the first time in Great Britain for 235 years. It was of the bubonic type with a low power of infectivity, for although it was at least three weeks in the city, and probably much longer, before its true nature was suspected or even dreamt of, and during that time 800,000 inhabitants exposed to infection, yet there were only 36 known cases traced with 16 deaths. The origin of the outbreak was never discovered. The second outbreak was in August of the following year, with two known cases in the original plague-infected area, and two months later there were six cases discovered in a city hotel. It was in this second outbreak that I came across a case which was no doubt plague. In THE LANCET of Nov. 30th, 1907, I fully described this case and offered strong presumptive evidence that it infected Liverpool by means of "contacts" who carried the infection in their clothes and caused an outbreak of plague in that city in September, 1901, in which there were eight cases with six deaths. The third outbreak of plague in Glasgow was last year and again in August. There were two known cases in the plague-infected area of 1900. In my opinion there were more cases, but I do not wish to mention in this letter any disputed cases. One significant fact is worth noting. Last year, for the first time in the three outbreaks, infected rats were detected and the disquieting fact was that they were found in Kinning Park, which is on the same side of the Clyde but fully a mile from the plague-infected area of 1900. These rats were accidentally discovered by giving rise to an offensive smell. They numbered 51 and had probably died at the same time. Only one of them was fit for bacteriological examination and Dr. R. M. Buchanan, the city bacteriologist, reported[1] that the bacillus pestis was found. A subculture proved virulent for a healthy mouse and a healthy rat within 48 and 72 hours respectively. Dr. Buchanan adds: "In view of the absence of any other probable cause of death of these rats it must be presumed that the others had also succumbed to plague." Finally, we have the second outbreak of plague in Liverpool and again in the autumn.

The first striking fact to be noted in these five outbreaks is their appearance at the same season of the year. Professor Simpson in his classical treatise on plague states that the season of the year has a powerful influence on plague, so powerful that he quotes Hodge's "Loimologia" that in the Great Plague in London in 1665, after the plague season was over, which was from August to November, the people returned to the deserted plague houses and even slept in beds where plague patients had died without contracting the disease. It is a most remarkable fact that these five outbreaks of plague in Great Britain from 1900 to 1908 should be exactly at the same season of the year as the London epidemics of 1603, 1605, 1625, 1636, and 1665. Hence I would suggest the following relationship between each of the five outbreaks. The infection in the first outbreak in Glasgow in 1900 was no doubt imported into the city either by a human carrier of the disease or by infected material, more probably the latter, at a season of the year most favourable to the development and activity of the bacillus pestis. There is not the shadow of a doubt that the other two outbreaks resulted from the first one and were not fresh importations into the city. They were a positive proof that the bacillus pestis, as in all modern outbreaks, had never left the city since 1900 in spite of all that was done to destroy it. The infection in the first outbreak of plague in Liverpool in 1901 was most probably brought into that city from Glasgow, as I have already described, by infected clothing, and in the absence of proof to the contrary I would now suggest that the infection in the recent three cases of plague in Liverpool is not a fresh importation but is related in some way with the appearance of plague in Liverpool in 1901.

I am no alarmist, so I do not look upon every patient with a bubo or with enlarged axillary and inguinal glands as a case of plague. Last year I examined fully 1000 patients of all ages and with all sorts of ailments and I was surprised to find how commonly the axillary and inguinal glands were palpably and painlessly enlarged, varying from the size of a pea to that of a bean in cases in which there was not the slightest reason for suspecting plague. The best corrective of medical bias is undoubtedly the practical experience of an extensive general practice. But we must face facts as we find them, and whilst I do not anticipate any more cases of true plague to appear in Liverpool or Glasgow this year I am convinced that true plague will appear in both cities again, especially from the beginning of August till the end of November. Hence all medical men in these cities should be specially on the alert, for unless they examine the axillary and inguinal and femoral regions in all atypical cases of illness they will certainly miss plague, for Prof. Simpson tells us that plague may simulate any disease and has been diagnosed as influenza, pneumonia, septicæmia, typhus, typhoid, relapsing fever, meningitis, diphtheria, syphilis, gonorrhœa, appendicitis, typhlitis, malaria, and filariasis with enlarged glands. All modern outbreaks of plague point to the fact that it clings most tenaciously to any place it infects and it has most marvellous powers of recrudescence and resistance to all known methods of disinfection and prevention. Plague may be so mild that we can toy with it, but we should never forget that we do not know when these mild forms, with low powers of infectivity, may develop into the virulent septicæmic and pneumonic forms with a high power of infectivity and that be purchased at a public house, renders the careful supervision of its sale a matter of importance to the community, and the firm named must also view with satisfaction the punishment of a deception calculated to injure their reputation if undetected.

Fever.—We should be interested to know the name of the person who has entered into such unprofessional relations with the newspaper.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Herbert F. Waterhouse, Walter G. Spencer): at 5.30 P.M.

Paper:

Dr. W. Ironside Bruce: X Ray Examination of the Urinary Tract.

PATHOLOGICAL SECTION (Hon. Secretaries—Leonard S. Dudgeon, O. Grünbaum): at the Lister Institute, Chelsea Gardens, Chelsea Bridge-road, S.W., at 8.30 P.M.

Papers:

Dr. Henderson-Smith and Dr. Candler: The *Wassermann* Reaction in General Paralysis of the Insane (with demonstration).

Dr. Harden and Dr. Thompson: Anærobiosis.

Dr. [illegible]

Prof[illegible] of Trypanosomes, including t[illegible] showing Myonemes).

Dr. [illegible] the Nature and Efficiency of certain Rat Viruses.

Dr. Kennaway and Dr. Leathes: Preliminary Note on the Examination of the Fat in Normal and Diseased Livers.

WEDNESDAY.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Llewelyn Powell, R. W. Collum): at 8.30 P.M.

Paper:

Dr. N. H. Alcock: 50 Cases Anæsthetised with known Percentages of Chloroform, with a Description of the Apparatus employed.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—H. Beckett-Overy, William J. Gow): at 7.45 P.M.

Papers:

Dr. A. W. W. Lea and Dr. Sidebottom: Organisms present in the Uterine Secretion during an *Afebrile Puerperium.*

Mr. Alban Doran: Fœtus and Placenta *from a Case* of Extra-uterine Pregnancy. Operation at end of Fifth Month.

Mr. H. J. Paterson: A Case of Extra-Uterine Pregnancy. Operation *during* the Sixth Month of Pregnancy.

Specimens:

Dr. J. H. Dauber: Hysterectomy for Cervical Fibroid during Pregnancy.

Dr. J. S. Fairbairn: Necro-biotic Fibroma from a Patient Three Months Pregnant.

Dr. Keyworth: Uterus and Appendages from Fatal Case of [illegible] showing Intraperitoneal Bleeding [illegible]ibes.

Mr. [illegible] Case of Diffuse Adeno-myoma of the Uterus.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Raymond Johnson, H. D. Rolleston): at 8.30 P.M.

Cases:

Mr. Openshaw: Paralysis of the Lower Extremities.

Mr. Raymond Johnson: Renal Hypernephroma of Three Years' Duration.

Dr. E. I. Spriggs: Exophthalmic Goitre with Rheumatoid Arthritis.

Dr. G. A. Sutherland, Dr. Herringham, Dr. Rose Bradford, Dr. Weber, Dr. Spriggs, Dr. French, and Dr. Rolleston will show Cases of Anomalous Œdema.

Dr. Parkes Weber: Apparent Muscular Hypertrophy following Œdema of Left Leg.

Short Paper:

Dr. Parkes Weber: Mediastinal Lymphadenoma with Extreme Osteo arthropathy.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Mr. R. E. Griffiths and Prof. Greenish: Microscopical Identification of the Green Extracts (communication from the Pharmaceutical Research Laboratory).—Exhibition of Lantern Slides and Specimens by Mr. W. G. Freeman, Prof. Greenish, and Mr. Holmes.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—5.30 P.M., Dr. Brodribb (Hastings): The Therapeutic Use of Sea Water.—Dr. Midleton (Bournemouth): Rheumatic Affections treated by Counter-irritation of the Spine

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Dr. V. Bonney: Carcinoma of the Cervix.

OPHTHALMOLOGICAL *SOCIETY* OF THE UNITED KINGDOM 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Exhibits by Dr. T. Henderson and others. 8.30 P.M., Mr. G. B. James: Note on the Operative Treatment of Strabismus.—Major Elliot, I.M.S.: Some Observations on Cataract Extraction.—Dr. A. Bronner: Iridectomy in Cases of Acute Iritis in which the *Pupil* cannot be Dilated.

CHILD STUDY SOCIETY LONDON, Parkes Museum, Margaret-street, W.

THURSDAY.—8 P.M., Dr. J. Kerr: The Educational Revolution and some Hints for the Future.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND *POLYCLINIC*, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. Macleod: Clinique (Skin). 5.15 P.M., Lecture: Mr. M. Little: Flat Foot.

TUESDAY.—4 P.M., Dr. T. Williams: Clinique (Medical). 5 P.M., General Meeting.

WEDNESDAY.—4 P.M., Mr. C. [illegible] Lecture:—Dr. D. Ferrier [illegible]

THURSDAY.—4 P.M., Sir Jonat[illegible] 5.15 P.M. Lecture:—Mr. A[illegible] of the Biliary Passages.

FRIDAY.—4 P.M., Mr. E. Clarke: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Surgical Cases. 12 noon, Dr. Low: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture.—Dr. Lloyd: Anæsthetics.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Bilharziosis.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Surgical Cases. 2 P.M., Medical and Surgical Clinics X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture —Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 3 P.M., Lecture:—Dr. R. Jones: General Symptomatology of Insanity (at Claybury Lunatic Asylum, Woodford Bridge, Essex).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Sir Dyce Duckworth: Medicine. 3.15 P.M., Mr. Turner: Surgery. 4 P.M., Mr. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture:—Sir Dyce Duckworth: Dyspepsia due to Alcoholic Abuse.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. *Carless*: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Wm. Bennett.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. Carson); X Rays. 4.30 P.M., Medical In-patient Clinic (Dr. A. J. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations (Mr. Carson). Clinics:—Surgical (Mr. W. Edmunds) Gynæcological (Dr. A. E. Giles). [illegible] (Dr. T. R. [illegible] P. Brooks).

WEDNESDAY.—Clinics:—2.30 [illegible] Whipham); Skin (Dr. G. [illegible] 4.30 P.M., Dr. S. J. Gilfilla[illegible] [illegible]s of Mental Disease at the Colney [illegible] E. Giles).

THURSDAY.—2.30 P.M., Gy[illegible] Surgical Clinics:—Medical Out-[illegible] X Rays. 3 P.M., Medical In-patient (Dr. (Mr. H. W. Carson); [illegible] G. P. Chappel).

or both should be destroyed, while in others the trunk of the auditory nerve should be divided.

I am, Sir, yours faithfully,
Dec. 1st, 1903. CHARLES A. BALLANCE.

STANDARDISATION OF DISINFECTANTS.

To the Editor of THE LANCET.

SIR,—Many manufacturers of disinfectants are to-day seriously inconvenienced by the absence of an authoritatively determined and fixed or "standard" method of conducting bacteriological tests for disinfectants. We, like most of our competitors, are anxious that some standard should be authoritatively set forward, and suggest that a committee appointed by the British Medical Association, the Royal College of Surgeons, or the Royal Society would be suitable for such a task, and we hope for your assistance in making this demand.

In your issue of Sept. 19th, p. 902, a letter appeared in your columns upon this subject from Messrs. Rideal and Walker, the joint authors of what is known as the "Rideal-Walker" method (of bacteriological test for disinfectants), and this letter introduced a new and important condition into that method, thereby constituting a *serious modification* of the method. As this condition had not hitherto been embodied in the test our preparations up to that time had *not, of* course, been tested under this condition, but we at once took steps to insure that our product should have a guaranteed coefficient of 17 or over when tested by the newer Rideal-Walker method, involving the new conditions insisted upon by Messrs. Rideal and Walker. In the meantime, however, we suffered from comparison on account of Messrs. Jeyes (of whom Mr. Ainslie Walker is managing director) publishing a test of our fluid according to the new method showing a lower coefficient than that guaranteed by us. They examined our old fluid by the new test and endeavoured to make the public infer that we did not keep our product up to our guaranteed efficiency. We have pointed this out to them and shall take legal steps to defend our reputation if necessary.

We have, however, said enough to show that the matter is one vitally affecting the interests of manufacturers and we beg your support in asking for an authoritative determination of a standard method for testing the bacteriological efficiency of a disinfectant. We feel sure that Messrs. Jeyes' Sanitary Compounds, Limited, and other manufacturers, will be as ready as we are to have such a standard fixed by an impartial expert authority. We may add that we are prepared to subscribe equally with any fellow manufacturers of disinfectants towards the expense of such investigations and determinations and only ask that the body appointed should be absolutely impartial and that it should not contain any members interested directly or indirectly in any particular disinfectant. We are certain that your advocacy of our proposal will meet with the grateful appreciation of both manufacturers and health authorities.

We are, Sir, yours faithfully,
Dec 1st, 1903. McDOUGALL BROS.

⁂ Sanitarians, and medical men generally, recognise the need for a standard method of conducting bacteriological tests for disinfectants. Such a test should clearly be only alterable after proper investigation by an impartial and expert authority.—ED. L.

"THE HUMAN WOMAN."

To the Editor of THE LANCET.

SIR,—The authoress of this work will, I hope, reply to the arguments of THE LANCET. I, as a medical woman, wish to make a few remarks from the medical standpoint. Trotula and her compeers did not hand down an uninterrupted chain of noted medical women to the present day, for the chain was broken when women ceased "to enjoy equal chances with men." The causes of this change are a matter of history, warfare being one of the chief causes. The writer looks forward to statistics of the achievements of medical women 50 years hence. He assumes that women are "entering the lists on equal terms with men as regards education." I disagree. In London the women study at one general hospital only, and that one of the smallest. After qualification comes one of the most important times for medical education—viz., the holding of residential hospital posts. These are not open at any of the large hospitals, not even in Newcastle, where the students have co-education. Two such posts are open at the Women's Hospital in London. Other posts held by women are mainly as officers of infirmaries where the excessive work allows of little or no individual study of cases. Moreover, the large majority of medical women are thus obliged to go to London for experience. Here, again, the large hospitals and their undermanning are sufficient to prevent true research work. So that I fear that unless medical education is really put on a similar footing for men and women and opportunities for scientific research are given to women under our best leaders and in our best pathology and bacteriology laboratories the contribution of women to medical science 50 years hence will still be extremely small.

The idea of the "new chivalry" is the one I uphold. Let the boards of men who appoint a woman as officer to their institution give her a salary fitted to her position, not appoint a junior man with a higher salary to work with her, and force her to retire from the unequal competition or from force of circumstances to hold on against her professional honour and accept the degradation. As to the physical disabilities, I think certainly that married women during their child-bearing period would be incapable of personal attendance at assemblies provided she gave the child the nutriment so necessary to its welfare, and such women could never fill a Cabinet Minister's position. But there are many years when a married woman could fulfil the duties of an ordinary Member. One of our best-known women surgeons is still enjoying a distinguished career and her son and daughter are in the same profession.

Such women as suffer from a physical incapability of such intensity as to prostrate them for a few hours or days would also be prevented from the very highest executive duties, but again I maintain for the lesser duties of a Member of Parliament she would be fitted. The statistics on such cases compared with those of monthly absentees for from one to three days of Members of Parliament for asthma, toothache, migraine, or excellent dinners would be of great interest. The first set of statistics are now being collected by a member of the Registered Medical Women's Association and should shortly be published. I am, and I think most women are, of complete agreement with the idea that "marriage is the best thing that can happen to her.". I would add, however, this qualifying clause. The man must be a "human man" or the cultured class of women who, if any, will take on the executive will go unmated and in full career to the end. THE LANCET article has, I think, given a handle to the people of England to say, "Ah, you see THE LANCET says women are physically unfitted," but I imagine THE LANCET would not express an adverse opinion to women holding the power of voting for a representative in Parliament. This representative need not of necessity, as THE LANCET seems to assume, be a woman. This is the political reform for which women are now pressing.

I am, Sir, yours faithfully,
Nov. 23rd, 1903. M. F.-T.

THE NEW LUNATIC ASYLUM AND MENTAL SANATORIUM "AM STEINHOF" IN VIENNA.

(FROM OUR VIENNA CORRESPONDENT.)

THE latest addition to the charitable institutions provided by Lower Austria for its mentally affected people is the new institution called "Am Steinhof," which has the reputation of being the most modern, best-equipped, and largest institution of this kind in the world. The asylum comprises 60 separate pavilions and consists of three well-separated sets of buildings, the asylum, the sanatorium, and the administrative wing and nurses' quarters. A commanding view is obtained from all the front windows, as the institute lies on the south-western slope of the Satzberg, one of the hills on the outskirts of the city, about 950 feet above sea level and 300 feet above the average level of Vienna. The direction of the winds is in this part mostly south or south-east, and they bring with them a limitless supply of fresh air from the Alps, which can be seen distinctly from all parts of the

Nearly the whole quantity of vegetables consumed, together with other foodstuffs such as pork and butter, are produced within the institute partly by the agricultural work of the patients. The entire cost of this enormous institute was 20,000,000 crowns, or £850,000, which works out at £280 per bed.

BRISTOL.

(FROM OUR OWN CORRESPONDENT.)

University College, Bristol.

THE annual meeting of governors of University College was held on Nov. 18th, the Right Hon. Henry Hobhouse being in the chair in the absence of the Bishop of Hereford. The adoption of the registrar's report was moved by the Right Hon. Lewis Fry who dwelt on the many evidences of progress afforded by a review of the past year. Amongst others, there was the fact that the number of medical students was 107, the highest figure yet attained. In the formation of two readerships of law might be seen the beginnings of a school of law for the West of England which in a fully developed university might examine for, and grant, degrees. A chair of anthropology had been founded, its first occupant being Dr. John Beddoe, the President of the Anthropological Society. Against this record of progress he had to set a financial deficiency, incurred in spite of a rigid economy in administration. Mr. Fry then turned to the subject of the University movement and referred to the impetus which it had received from Mr. Henry Overton Wills's splendid gift of £100,000. This and further gifts, with support from the city council and other influential bodies, had emboldened the council of the college to apply to His Majesty's Privy Council for a University charter. At his recent visit the King had referred in terms of keenest sympathy to this application. Unhappily the Society of Merchant Venturers had seen fit to object to the petition as presented by University College on the ground that the prestige of its own technical college would be damaged by its inclusion in the University under the conditions suggested. The college council had not yet been able to arrive at a complete understanding with the society; but it had felt that delay was undesirable, so that on the previous day (Nov. 17th) its petition, with the draft charter, had been laid by the Privy Council on the table in both Houses of Parliament.

The University Charter.

An outline of the charter to which I have referred appeared on Nov. 20th in the *Western Daily Press*, which has throughout supported the University scheme with vigour. Provision for the granting of degrees and the holding of examinations is made; in all except entrance examinations there must be at least one external examiner to each subject. Power is to be given for incorporation of University College and the Society of Merchant Venturers is to be asked to provide more especially for the Faculty of Engineering. Then follow provisions for the government of the University. The supreme body is the court, executive and financial control resting with the council. This latter is to include, among others, a chancellor (Mr. H. O. Wills), three pro-chancellors (the Bishop of Hereford, Mr. Lewis Fry, and Lord Winterstoke), and two vice-chancellors (Mr. Henry Hobhouse and Principal Lloyd Morgan). The last named will be *ex-officio* chairman of the Senate.

Coloured Micro-photographs.

To illustrate a paper read by Mr. T. M. Carter at the November meeting of the Bristol Medico-Chirurgical Society on a case of basal hæmorrhage of doubtful nature, Dr. I. Walker Hall showed some lantern slides which were produced by applying the Lumière process to micro-photography.[1] Sections through a blood-vessel were shown at the point of the leak which had given rise to the hæmorrhage. The red colour of connective tissue after treatment with van Gieson's stain was accurately represented, and the elastic lamina of another vessel, picked out by Weigert's stain, was very clearly demonstrated. Other less definitive stains gave indistinct results; but the general effect of the slides on the screen was quite sharp enough to establish the value of this new method of demonstration.

Bristol General Hospital.

Dr. E. V. Dunkley, pathologist to the Bristol General Hospital, is resigning a post which he has filled with credit. His place is to be taken by Dr. E. Emrys-Roberts who has been engaged in research and teaching at Liverpool for several years. Dr. Emrys-Roberts will also act as assistant to Dr. Walker Hall, professor of pathology at University College. This is another step in the union between the College and the Bristol hospitals which is gradually taking place to the great advantage of the medical school.

Hospital Sunday Fund at Bristol.

At a meeting of the committee of the Hospital Sunday Fund held at the Guildhall, Bristol, on Nov. 23rd. it was decided that Jan. 31st, 1909, should be observed in Bristol as "Hospital Sunday." It was stated that in 1908 the sum of £1859 was collected and a strong effort is to be made to raise at least £2000 next year. A clerical member of the committee suggested that as only about 15 per cent. of the population attended places of worship something should be done to get the practical help of the other 85 per cent.

Dec. 1st.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE Huxley lecture on Malaria, delivered last week by Professor R. Ross to a large audience, was an interesting exposition which embraced a consideration of the main features of the micro-organisms concerned, the hosts which they infest, the areas in which they are found, and the positions which they choose for breeding-grounds. The lecture opened with a brief historical survey, in which Professor Ross stated that an investigation of Greek and Roman literature had proved that the disease was well known in ancient days; its main types were then clearly defined and its association with marshes was ascertained, but naturally the true cause and the mode of infection did not come within the range of Greek or Roman knowledge. Professor Ross demonstrated by means of statistical tables the widespread character of the disease and he pointed out that though it could not be called a very fatal disease nevertheless it probably killed two or three millions of the inhabitants of India every year. He referred to the difficulties which he had met in trying to get authorities to take the measures necessary for the eradication of the pest and proved by the results obtained in Ismailia that eradication was comparatively cheap and usually quite easy, but it must be admitted that in some cases, as his lantern slides demonstrated, the necessary measures convert charming sylvan spots into uninteresting if more healthy places.

The Dental Hospital.

The annual report of the Birmingham Dental Hospital shows a remarkable growth in the amount of work performed by the hospital staff. As contrasted with the previous year the number of attendances had increased by 1633, the extractions by 2516, the fillings by 1493, and the dressings by 1115. The treatment of the Summer-lane school children being completed in the spring, that of the Bristol-street school was then commenced, and the report of the examination of the children confirmed the result arrived at in Summer-lane, which demonstrated that 69 per cent. of the children attending the council schools have defective teeth. This is a very large proportion and it will be interesting to find if other cities and districts arrive eventually at the same results. It is already evident, however, that either opinions differ as to what constitutes a case of defective teeth or the proportion of defective teeth differs considerably in districts not very far apart, for the result of the medical inspection as carried out in King's Norton gave 71 per cent., that in Smethwick 15·6 per cent., and the result of the examination of 2373 children in Worcestershire gave about 10·6 per cent. of defective teeth.

A Convalescent Hospital for Crippled Children.

The Birmingham and District Crippled Children's Union is making an appeal for funds to establish a satisfactory convalescent hospital for the crippled children of the city district. The Woodlands at Northfield, which Mr. George

---

[1] THE LANCET, Nov. 28th, 1908, p. 1594.

The problem, then, now before us is, how is the transport service carried on between the seat of glycogen accumulation in the liver and the seat of utilisation in the tissues, without leading to any show of its occurrence through the detectable appearance of sugar?

I have dealt with this matter in my "Carbohydrate Metabolism and Diabetes" (p. 68), and have suggested that the

TRANSPORT IS EFFECTED BY THE GLYCOGEN MOLECULES BECOMING IN THE FIRST INSTANCE BROKEN DOWN

by enzyme action, just as occurs with starch molecules in the vegetable kingdom, into molecules of sugar, and then that these sugar molecules become linked on as side-chains to protein molecules and thus conveyed in a locked-up, large molecular state to the tissues, where they become taken off according as they are wanted.

This is nothing more than what happens in the ordinary course of chemical procedure. I have previously spoken about side-chains being taken on to a central ring or nucleus, and the capability of their being afterwards withdrawn without disruption of the nuclear body. The matter resolves itself into a question of the strength of affinity operating in one direction or the other. So it may be with sugar molecules linked on to a molecular blood complex. If they should be brought under the influence of a tissue complex in want of them, and thereby possessing a stronger affinity for them, it is only in the natural order of things that they should pass from the one to the other.

The train of phenomena would be that as the side-chains of the complex tissue molecules become worked off, they require to be replaced by fresh side-chains from the blood, and, in turn, the removal of these side-chains creates a demand which leads to the storage being drawn upon. Now, if the storage, as in the case of glycogen, is not of a nature to be adapted for shifting its position, it must of necessity be placed in a suitable condition for doing so. Here comes in the requirement for enzyme action, and it is suggested that as the storage is wanted, provision is made, through enzyme agency, for its supply in a form to meet what is needed.

Viewing matters in this way, the

SIDE-CHAIN WANT IN THE BLOOD LEADS TO THE STORAGE GLYCOGEN BEING

put into a suitable state to fill the void, and thus circumstanced, the carbohydrate becomes transported from the seat of accumulation in the liver to the seat of utilisation in the tissues without passing in a state to run off with the urine, as, in the free small molecular state of sugar, it would otherwise do in proportion to its extent of presence in the blood.

The idea here broached stands in conformity with the accepted view of what occurs in connexion with the transport of oxygen. Hæmoglobin is the agent concerned in the process. Taking on oxygen in the lungs, it travels as oxyhæmoglobin to the tissues, and gives up the oxygen that is needed to replace that which has been consumed in the bioplasmic molecules. Thus unloaded and made ready for recharging, the hæmoglobin is conveyed back to the lungs, where a fresh intake of oxygen occurs. Thus the round is effected by the capacity possessed by hæmoglobin of taking oxygen into chemical union of a sufficiently feeble nature to permit of its being subsequently dissociated to meet the demand of the tissues. I urge that we have here a parallel of what occurs in the case of the transport of carbohydrate from the seat of accumulation in the liver to that of utilisation in the tissues.

In this transport of carbohydrate I have assumed that it passes in the form of a side-chain linked on to a large moleculed constituent of the blood. As yet we have no distinct evidence before us to show what this constituent really is. Probably it is of a protein nature, and if so, we have material at hand to open out a consistent train of reasoning of much interest and importance standing at the root of what is being dealt with. Let me enter into particulars and expound what I refer to.

What is wanted for transport service is that the

CARBOHYDRATE SHOULD BE LOOSELY LINKED ON TO THE CARRYING MOLECULE,

so as to be susceptible of being disjoined without involving the disruption of the molecule itself. Evidence, as we shall see, is producible attesting the existence of such a state. At the same time, let me say that evidence is also producible having the effect of showing the existence of carbohydrate in another state in the molecule—in a state so closely locked-up as not to be susceptible of liberation apart from the disintegration of the molecule. Both points, it will be found, have important practical bearings connected with them.

That the existence of carbohydrate in a loosely combined and in a firmly locked-up state in a molecule is no mere hypothesis is capable of being made manifest by what is seen when amygdalin is exposed to different kinds of enzyme action. A molecule of amygdalin has two molecules of carbohydrate within it. When subjected to the action of glucase, the ferment which transforms maltose into glucose, a molecule of glucose is split off without the production of any further effect, which means that the other molecule is left untouched. In contact with emulsin, however, both molecules are liberated, with benzoic aldehyde and hydrocyanic acid as associated products. The conclusion to be drawn from these results is that the two carbohydrate molecules within the amygdalin molecule are differently placed—that one is in a position to be easily detached without leading to other disturbance, whilst in the case of the other, its liberation involves molecular disruption as an attendant phenomenon.

A study of the effects of

PHLORIDZIN AFFORDS IMMENSE HELP IN UNRAVELLING

the intricacies of the question that is being considered, and it points in a very decisive manner to the existence of carbohydrate within the molecular complex, as a side-chain attachment on the one hand, and in a locked-up state in the nuclear centre on the other. It, moreover, goes further, and gives grounds for associating the side-chain attachment with transport service, leaving the locked-up portion as constituting a component incorporated during the construction of the molecule, whether in lymphocyte growth from food, or in bioplasmic growth elsewhere.

Phloridzin, as is well known, is an active producer of glycosuria, and its action in this direction is exerted through the coöperation of the blood and the renal cells. The sugar does not, as in other forms of glycosuria, take origin elsewhere and travel to the kidney preparatory to elimination, but comes into view during the act of secretion of the urine, and in the absence of the kidneys phloridzin fails to produce any visible effect within the system. It is obvious, therefore, that some constituent of the blood other than sugar must be concerned in the production of the glycosuria. The output of sugar is sufficiently large and continuous to show that there must be something to feed the blood to keep up the discharge occurring, and, coincidently with the outflow, it is noticed that a disappearance of storage glycogen occurs. Indeed, phloridzin supplies us with one of the most effective means of rapidly clearing away glycogen from the liver and the muscles.

That the blood is fed in the way suggested is supported by the

EVIDENCE DERIVABLE FROM LIVER ABLATION EXPERIMENTS.

It is possible for the life of an animal to be maintained for some hours after the removal of the liver and its associated viscera in the abdomen. In a paper published in the *Journal of Physiology*[2] "On the Mechanism of Phloridzin Glycosuria" by Pavy, Brodie, and Siau, results are given which show that the sugar elimination declines after phloridzin injection at an infinitely greater rate in the liver ablation experiments than in control experiments where the viscera in question were left intact. It further appeared, when the sugar elimination had almost completely stopped, that a fresh start was given to it by transfusing into the vessels defibrinated blood derived from another animal.

Taking the fact that glycogen, as a result of phloridzin administration, disappears from its seats of accumulation, and that sugar contemporaneously shows itself in the urine, let us follow the matter on and see what the fact mentioned leads up to. The glycogen itself does not travel to the kidney and there constitute the source of the sugar that springs into view. As a first step in the operation occurring, it is not permissible to do otherwise than conceive that the cases where the sheriff is satisfied that the article is not intended for sale for human consumption no order for condemnation is given. Compulsory powers of entry into premises for purposes of examination are given to the medical officer of health, who is also given power to take samples from consignments, while officers of Customs are required to afford facilities for the examination of articles of food by the medical officer of health. In the circular issued with the regulations the Local Government Board emphasises the necessity for the medical officer of health so conducting his examination as to cause as little trouble and inconvenience to traders as possible. The "Foreign Meat Regulations" are designed to deal with meat brought from abroad and will therefore apply more especially to meat imported from New Zealand, the Argentine, and the United States. The definition of meat is very comprehensive and is stated to mean "pork, the flesh of cattle, any other edible part of a pig or of cattle, or a substance, compound, material, or article of which pork or the flesh of cattle, or any other edible part of a pig or of cattle, is an ingredient." The regulations divide foreign meat into four classes. The first class, termed in the regulations "Foreign Meat of Class I.," is designed to deal specially with boneless meat. The trade in this class of meat has grown in recent years and this meat, owing to its cheapness, is much consumed in the poorer districts and among the working classes. It is used chiefly for mincing purposes. The form in which it is imported, however, renders it difficult of inspection for detection of disease, and hence the special reference to it in the regulations. The Local Government Board points out, however, that the effect of the regulations is not to prohibit entirely the importation of boneless meat but only of the forms known as boneless scrap meat. If the meat is imported in such shape or such condition as to afford sufficient means of identification with definite parts of a carcass it will not fall within the terms of Class I. Meat of Class I. is prohibited entry into the country for purposes of human consumption. In order to prevent the detection of evidence of tuberculosis in pigs the lymphatic glands about the throat and elsewhere are removed, and the regulations provide that pig carcasses without those glands and without the head in its natural state of attachment (defined as Foreign Meats of Class II.) shall also be prohibited entry. The third class refers to several parts of a pig not prepared as bacon or ham but dressed and packed under satisfactory conditions, as evidenced by an attached certificate to that effect. The fourth class includes all other kinds of meat, and along with meat of Class III. is dealt with on its merits according as it is sound or unsound. When the officer of Customs ascertains that the cargo of a ship comprises meat of Class I. or Class II. he informs the medical officer of health to that effect. In regard to meat of Classes III. and IV. he is required to inform the medical officer of health only where "by reason of facts brought to his knowledge or of representations made to him" he is of opinion that the meat requires examination. As already indicated, meat of Classes I. and II. is not allowed entry unless the importer can satisfy a sheriff, magistrate, or justice that it is not intended for sale for human consumption. The object of the regulations which will come into force on Jan. 1st is that imported meat shall be dealt with by public health authorities at the place of importation. The disadvantage of the new regulations is the unequal dividing of the burden of inspection, which so far as Scotland is concerned will fall almost entirely upon Glasgow. There is no doubt, however, that a regular and systematic inspection by duly qualified officials will result in improvement in the quality of meat supplied.

The University of Aberdeen: Induction of Professor Dean.

At a fully attended meeting of the Senatus on Nov. 24th Professor George Dean was inducted to the chair of pathology, lately held by Professor D. J. Hamilton, retired. Principal Lang occupied the chair and in welcoming Professor Dean said: "Gentlemen, we have the pleasure of receiving to-day the Commission of the Crown in favour of Dr. Dean, whom, from to-day, we shall call Professor Dean." The secretary then read the Royal Commission, the members of the Senatus meanwhile standing, and after Principal Lang had concluded his formal welcome the right hand of fellowship was extended to the new professor. Professor Dean will begin to discharge the duties of the chair after the Christmas vacation.

Generous Bequests of an Elgin Merchant.

Mr. John Munro of Elgin, who died on June 29th last, has left, subject to the life use of his sister, Mrs. Isabella Tulloch, his residence, "The Knoll," Elgin, with grounds and buildings, to the Lord Provost, magistrates, and councillors of Elgin, for use as a home for persons suffering from incurable diseases, preference being given to inhabitants of the county of Elgin. Subject to £1000 upon trust for the benefit of Leanchoil Hospital, Forres, and other bequests, he left the residue of his property to his sister, Mrs. Isabella Tulloch, for life, with remainder to the Lord Provost, magistrates, and councillors of Elgin, as an endowment for the aforementioned home, to be carried on by them.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Recorder of Dublin on Squalor and Crime.

THE Recorder of Dublin has once again taken the opportunity of recurring at the opening of the City Criminal Sessions to the inevitable association of squalid poverty with terrible crime. In his address to the grand jury, after referring to the small number of 16 cases—all "simple"—with which they had to deal, he proceeded to observe that he "felt assured that they would be happy to know that although the state of the city was not all that they desired, yet there was much to congratulate themselves on in the absence of the more gross and serious classes of crime. He had so often called attention to the main sources of crime, intemperance, and disease in their midst, and with such barren results, that he regarded any effort to arouse the public conscience to the terrible condition of the working poor, and the squalid and loathsome slums in which they are housed, as hopeless. The toiling masses of the city would, he feared, be left to rot in their sunless lairs until the growth of crime and the scourge of pestilence compelled the attention which the call of humanity had failed to secure."

St. Vincent's Hospital, Dublin.

A large congregation assembled at the annual Requiem Office and High Mass for the deceased founders and benefactors of St. Vincent's Hospital, as all classes of Dublin society are interested in the welfare and progress of this institution because of benefits received directly or indirectly. Few institutions of its class in the whole area of the British Empire have carried out more thorough and effective work during the past quarter of a century, within the proportional limits of its accommodation, while all the necessary money has been obtained from the contributions of the sympathetic public. At a time when the general hospital nursing of Dublin was for the most part carried out in a haphazard manner the sisters of charity attached to the hospital organised a system of nursing which rapidly proved effective, and this is always remembered to its credit.

Castlerea Board of Guardians v. the Local Government Board.

The Castlerea board of guardians has been exceptionally prominent during the greater part of this year in its antagonism to the Local Government Board regarding the jurisdiction and arrangement of medical matters. I have already referred in this column to the fact that the board opposed the superannuation allowance of the late Mr. S. McDermott of Ballaghaderin, the result of which was that when the Local Government Board used its legal power to right the wrong the veteran medical officer did not live to receive the first instalment of his pension. On Nov. 23rd, in the King's Bench Division (before the Lord Chief Justice, Mr. Justice Gibson, and Mr. Justice Kenny), an application was made on behalf of the guardians of the Castlerea union in resistance to an Order of the Local Government Board of Sept. 18th last which purported to re-divide the dispensary districts of the Castlerea union and to appoint to the three districts certain medical officers and midwives. The districts involved were Castlerea, Castleplunket, and Ballaghaderin. The guardians objected to the Order on the alleged ground that it was an over-riding of their rights. They were prepared to agree to a re-division of the union, but the Local Government Board asked them to agree to a particular which was forwarded to him. At p. 68, the text runs: "The *suggestion presents itself that sugar is taken* on as a side-chain by a proteid constituent of the blood and transported to the tissues, where it is taken off for subjection to utilisation. The suggested operation is identical with what occurs in connexion with the transport of oxygen. Oxygen is taken on by hæmoglobin, and, in a state of combination, transported to the tissues, where it is taken off and applied to utilisation. Glycogen is a storage material consisting of very large molecules and therefore not adapted for shifting its position. I should think that the first action that occurs is the breaking down of its molecule into molecules of glucose, which become instantly taken on by the alluded-to molecules of the blood. There may be concerted action between the breaking-down and taking-on processes, and that there is such in operation is rendered probable by the fact that there is no show of sugar in connexion with the occurrence. Enzyme action, it may be considered, of necessity constitutes a part of the process, and the enzyme concerned, and set in motion as needed, may, in the presence of altered conditions, be intelligibly conceived to be capable of producing the deviation from the natural living state with respect to sugar that so quickly takes place as a post-mortem occurrence in the liver."

On the following page, in speaking of the effect of phloridzin, the statement is to be found: "The first effect of the phloridzin is to sweep away the glycogen that is present in the different parts of the body. If this passed through the circulatory system as free sugar there ought to be hyperglycæmia in proportion to the glycosuria, which there certainly is not. This being the case, the only conclusion to be drawn is that the katabolised glycogen (sugar) enters into side-chain or loose combination with a constituent (proteid) of the blood, and is thus conveyed to the kidney where it is set free and eliminated."

It will be seen that the view that can be now put forth, emanating from the knowledge that has been acquired during the last few years, and embodied in the work alluded to, has failed to receive Professor Halliburton's consideration. The effect of the proposition is to take away the ground from beneath his argument and destroy its reality. Previous to the recognition of carbohydrate as a constituent of protein, there could be no conception of what is permissibly entertainable now, and it must be admitted that a difficulty stood in the way of reconciling the facts observable in connexion with the changed state of things occurring in the liver at the moment of death. On the one side, evidence showed that if sugar passed into the circulation as had been suggested, the fact of its doing so could not escape being revealed by the urine, and the state of the urine negatived the possibility of the occurrence taking place. On the other side, there was the active production of sugar that was observed to occur in the liver as a post-mortem effect, and which, if occurring during life, would have established a different state of things from that actually found to exist. In these circumstances, it could only be said that the enzyme action allowed to come into play after death must be inhibited by the conditions existing during life.

With the knowledge that we now possess, it may be considered that no incompatibility exists. Concerning enzyme action, a considerable advance has been made, and it is consistent with what is now known to consider, in relation to the transformation of glycogen into sugar, that the agent concerned in effecting the process does not primarily exist in the liver in the state of enzyme, but in that of zymogen. Enzymes are dual bodies, and the mother substance of them, zymogen, possesses no activity. The cooperation of another body, the activator, is required to give it enzymic power. In other instances, the activator is brought into play as it is required, and here the conditions leading to a

DEMAND FOR CARBOHYDRATE FROM ITS STORAGE MAY SET THE ACTIVATOR FREE AND START THE ENZYME INTO MOTION

in the manner needed. It may well be that the altered conditions occurring at death may lead to a removal of the restraining influence that held things in proper check during life. The same may be said with regard to blood coagulation. The zymogen, or pro-ferment, of thrombin is present, but is devoid of activity, so long as the coöperative agent is held from exerting its activating effect.

Looking at the distinguished position that Professor Halliburton holds as a teacher of physiology and the weight that his writings carry in the mind of members of the medical profession, I cannot help regarding it as very regrettable that the evidence which nullifies his argument should have escaped being noticed. It is medicine that suffers in connexion with the matter, for without a right physiological basis, there can be no rational comprehension to guide the medical practitioner in dealing with the wrong metabolism which stands at the root of diabetes.

Is it to reversed enzyme action that the conversion of glycogen into sugar is due? Everyone admits that the building up of glycogen from sugar constitutes an important function of the liver. We look to enzyme action as the agency effecting the process, and it is now recognised that, by altered surrounding conditions, the line of action that has been in operation may be changed into one of a reverse nature. I see nothing inconsistent with the building-up enzyme in the cells of the liver being influenced by its environment in such a manner as to lead to the occurrence of a reversal of action, and thus to give rise to a breaking down of the previously built-up glycogen into sugar.

It is interesting to note the analogous behaviour that is traceable between

CARBOHYDRATE AND FAT IN THEIR CONNEXION WITH BIOPLASM,

and to this point I will now proceed to direct attention. We have seen that carbohydrate becomes incorporated in the bioplasmic complex, and that, if not consumed when there brought into relation with oxygen, another component of the complex, it may, under circumstances of redundancy, be cleaved off as storage material.

The effect of modern research is to give to fat a place in the bioplasmic molecule, and thus to put it into the same position as carbohydrate. I need not, I consider, here enter into the details of this matter. It will suffice to state that there is evidence to show that fat may exist in a locked-up state in a protein compound in like manner to what occurs with carbohydrate. In these circumstances, the fat is in an out-of-sight state, but is susceptible of being brought into view by the disruptive agency of peptic digestion. It is only recently that this subject has fallen under consideration, but already it has made its way into prominent notice.

With the point reached, the position of things stands as follows: the bioplasmic molecular complex, which may be regarded as the representative of a living unit and thereby as the seat of the metabolic changes which give rise to the phenomena of life, contains both carbohydrate and fat incorporated within it. Through intramolecular action, set in motion by agencies of an enzymic nature, the various occurrences noticed to ensue may be conceived to be brought about. In the molecule, oxygen also enters as a constituent, and thus circumstanced, it is brought into close relationship with the carbohydrate and fat components with which the interactions occur that give rise to the development of energy. The play that takes place is not considered to consist of straight off or unbroken oxidation, but of oxidation, step by step, of the components of the chain of which the vanishing molecule is made up. The result, when the intramolecular procedure is normally carried out, is the production of carbon dioxide, water, and ammonia,—products devoid of latent energy. Should it happen, as may in the presence of abnormal conditions be the case, that arrest at an intermediate stage takes place, the effect is the throwing off of a product retaining unexhausted energy.

I have shown that, with a redundancy of carbohydrate, glycogen is dissociated for storage purposes. Condensation, or building up within the bioplasmic molecule, must be here in operation, seeing that it is in the form of sugar, and not glycogen, that the carbohydrate enters the molecule. Precisely the same sort of thing happens in the case of fat. Under the existence of a redundancy, fat becomes, by cleavage from the bioplasmic molecule, microscopically visible where none, whilst in a locked-up state, was previously to be seen. Here again constructive work must be performed, inasmuch as neutral fat is devoid of the needed dialysability to permit of its passage through cell membranes to reach the bioplasm within. The transport must occur in association with a dialysable state, and an enzyme—lipase—exists widely distributed through the body, which performs the office of breaking down fat into fatty acid and glycerine, associated with quinine the remedy is of great value. This communication was made at the Society of Tropical Medicine on Nov. 11th.

Primary Cancer of the Bronchi.

At a meeting of the Medical Society held on Nov. 28th M. Letulle described from his own observations three forms of primary cancer of the bronchi. The first is an ordinary interstitial cylindrical epithelioma. The second is active (*végétante*) and characterised by the formation of buds of atypical epithelioma. The third is cavernous and follows upon an old bronchiectasis. It is characterised by lobulated pavement epithelioma. The clinical signs are of an extremely varied character.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Government and Infective Disease.

A WELL-INSPIRED, if not wholly new, departure has been taken by the General Board of Hygiene with the view of disseminating among the masses the fundamental laws of health, and so of combating the ignorance and the prejudice which favour the attack and propagation of disease. These laws of health are also those which make for decency and decorum in public life, coefficients, in fact, of that civilisation which is the distinctive mark of the more advanced races. "Popular instruction for the protection of the individual against infective maladies"—such is the rubric of the series of publications which the Direzione Generale della Sanità has begun to issue towards the above-indicated end and the specimens of which now before me seem creditable alike to their initiators and their authors. The first on the list deals with small-pox; the second with scarlet fever; the third with measles; the fourth with "tifo petecchiale" (petechial typhus); the fifth with cholera; the sixth with "tifo addominale" (enteric fever); the seventh with dysentery; the eighth with ankylostomiasis (so frequent among the labourers employed in railway tunnelling); the ninth with tuberculosis; the tenth with pneumonia; the eleventh with malaria; the twelfth with diphtheria; and the thirteenth, now in the hands of the printer, with trachoma. Each of these brochures contains clear, succinct instruction as to the malady with which it deals—its mode of diffusion and its danger, immediate or subsequent, and, as to the infective agent itself, its origin and its vehicle, the channels by which it finds access to the system, and the predisposing causes. A graphic picture is afforded of the symptomatology of the various infections, and from this the reader is provided with opportune instructions as to how he may best insure himself against each disease. A thoroughly qualified practitioner has in each case been intrusted with the publication, and while stringently scientific as to his facts he writes in a clear style, intelligible to the fairly well-educated reader. The series is in course of distribution throughout all the centres of population, rural and urban, particularly among the masters of elementary schools, the directors of manufacturing works in town and country, the heads of public offices, to say nothing of the *medici condotti* (divisional practitioners) and others who may reasonably be expected to coöperate in the propaganda. There are four outstanding truths which the Direzione Generale della Sanità is particularly anxious to impress on the masses: (1) that disease is not to be considered as a fatality to which the human subject is inexorably exposed; (2) that disease is the product of special micro-organisms which, bred from without, find entrance into the system generally *per incuriam* (sins of omission or commission) on the part of the individual; (3) that contagion can be avoided or guarded against; and (4) that everyone who has the knowledge and the will can keep himself immune from infective disease. Nothing can be more laudable than the aim and the *modus operandi* of this hygienic crusade (as it may be called); but success must not be looked for all at once. Rome was not built in a day, nor is sanitary reform to be accomplished in a decade—particularly with a population wellnigh one-half of whom are *analfabeti*, and of whose young married couples (in the south) not 70 per cent. can sign the marriage-lines.

An Academic Strike.

"We are a carnival people," said Antonio Gallenga of his compatriots; and certainly the "demonstrations" of which the universities from the Alps to Etna have for the past week been the source and centre bear out the remark of the "Dean of the Italian Press." Besides Italy proper there is an "Italian Austria" as there is an "Italian Switzerland"—the Trentino and the Istrian Triangle in the former corresponding to the Canton Ticino in the latter; the preponderating language in both being that of Italy—to such an extent, moreover, as to make them the object of Italian reclamation under the banner of "Italia Irredenta." Thanks, however, to good, not to say sympathetic, government, the Swiss Italian has no inclination to revert to the motherland; but it is another thing with his Austrian counterpart. The Austrian *régime*, always loathed in Italy, has left behind it a bequest of ill-will amounting to race hatred, which has been fostered by grievances, real or imagined, which have never been allowed to die down. It is at the universities that this racial antipathy is most accentuated, and the collisions, often ending in bloodshed or even loss of life, between the Italian and the Austrian students have year by year been increasing in frequency and violence. Nay, in Vienna itself a "tafferuglio" (row) occurred the other day in which the Italians, outnumbered in the proportion of 10 to 1, had considerably the worst of it, and immediately thereafter a response of "sympathy and solidarity" was started in all the seats of learning throughout Italy, the students abandoning their studies, marching in procession through the streets, insulting every Austrian official (diplomatic or consular) whom they encountered, and colliding with the police who endeavoured to save the said officials from violence or the Italian public from suspension of traffic. The students, nothing loth to have an unauthorised holiday, have been patrolling the streets of the university towns in high glee and with scant consideration for the interests, business and other, of their compatriots, till a general cry of "Basta!" (enough) has risen from all classes, accentuated by leading articles in the press, official and non-official. The demonstrations, and the grievances from which they spring (chief among these being the want of an Italian university at Trieste), are now under consideration (diplomatic and Parliamentary) at Vienna and Rome, and there I am content to leave them. But may it be whispered that the Italian *Burschenschaft* is a little too prone to such outbreaks, too liable, on the slightest provocation, to take a side in international quarrels which concern them remotely, if at all; too given to "carnivalesque" proceedings, rhetorical and processional, and so to interrupt those studies on which their future acceptance as citizens depends—studies which they often deprecate as too severe or as leading up to examinations for which they are not always duly prepared? The university quadrangle, with its opportunity for high-flown harangues, seems more attractive for them than the university class-room, with its steady, if monotonous, routine, and the result is a "solution of continuity" in study and professional equipment which perhaps explains the rather poor output of the said universities in scholarship, science, and research. Such were not the youthful methods of the Galileos and the Torricellis, the Baglivis and the Morgagnis, the Leopardis and the Manzonis, to whom Italy looks back with pride and the civilised world with gratitude. Let us hope that these latest "demonstrations" will be the last and that, while the Italian and Austrian Governments will between them devise a better *modus vivendi* at their seats of learning where the two nationalities study in concert, the youth of Italy itself will develop more self-restraint and more practical appreciation of the old Hippocratic motto, "Ars longa, vita brevis."

Dec. 1st.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Renal Diseases and Cryoscopy.

AT a recent meeting of the Budapest Royal Medical Society Dr. Müller said that the cryoscopic examination of the blood of a certain number of very difficult cases had been of great value in determining the question of operation. He said that the method depended upon the well-known physical law that the freezing point varies with the osmotic density rather than with the specific gravity. Casper Richter, Kümmel, Koránya, and others carried out most of generally admitted to take place. It is not conceived, as at one time was done, that the food molecule is consumed in the form of an isolated entity. Toxins, when in a position to be incapable of being taken on by the constituent molecules of bioplasm, fail to exert any toxic effect. It is only when they become actually linked on to the bioplasmic molecules that the interactions that are needed to evoke the results which are capable of being produced by the particular toxin concerned, can occur. So with food molecules, they must be embodied into the bioplasmic molecules as a preliminary step to utilisation. Thus placed in these molecules, they are brought into relation with the other constituents, notably oxygen, which presumably is present in a loosely combined state as in oxyhæmoglobin, and put into a position to permit of the interactions attended with oxidation and the liberation of energy that are observed to take place.

Analogy may be appealed to for assistance in the comprehension of the procedure involved in

THE LINKING ON OF THE FOOD MOLECULE TO THE BIOPLASMIC COMPLEX.

We learn from what occurs in connexion with toxins and with lysins (hæmolysins and bacteriolysins), that there is an intermediary body, the amboceptor, through which the junction with the bioplasmic molecule is effected. In the absence of the play of this intermediary body, no junction and no effect follow the presence of the toxin and the lysin in the blood. A large amount of closely reasoned experimental work, with much of it of a test-tube nature, stands at the foundation of the conception that has been put forward, and gives to it a well-grounded qualification for acceptance.

Proceeding with the matter, it may further be said that, whilst the body that is linked on (in immunity phraseology called the complement) is thermo-labile or susceptible of destruction under exposure to a moderately elevated temperature, the agent that links on (amboceptor) may be exposed to a boiling temperature without losing its linking-on power, and is, therefore, in contradistinction spoken of as thermo-stable. This is an important point in connexion with the train of reasoning that I am about to set forth.

It is contended that the first step towards the utilisation of carbohydrate is linking on to the bioplasmic complex. Without susceptibility of being linked on, it simply filters through the body and runs out with the urine without being in any way touched. This is the case, for instance, with the disaccharides,—saccharose, lactose, and maltose, when under any circumstances reaching the circulatory system as such. With the monosaccharides,—dextrose, levulose, and galactose, on the other hand, we find that these, when present in the circulation, do not wholly escape in a similar manner. A portion fails to pass out with the urine, and this portion, it may be assumed, becomes put into the combined state, and subsequently made use of in the ordinary manner. If no capacity existed for linking on these monosaccharides, it is not conceivable that they would be any more susceptible of utilisation than the group which is not utilisable.

The effect following the introduction of the different sugars into the circulation by intravenous injection has been already alluded to. It has been seen that a certain amount of power exists of putting the monosaccharides into a position to be made susceptible of retention in the system. A great contrast, however, is to be perceived in the extent of power that exists at the seat of absorption in the alimentary canal to deal with the sugar derived from the food, as compared with that existing in the blood. Notwithstanding the large amount of carbohydrate that may be ingested with the food, we find, with its reception into the organism in a normal way, that it effectually becomes assimilated, or put into an altered state, and thus prevented reaching the general circulation as sugar. Introduced, on the other hand, in a direct manner into the circulation, the evidence afforded, alike by the urine and by analytical examination of the blood, shows that it is only comparatively slowly and in limited quantity susceptible of being thrown out of view, by the power that is here encountered.

Protein and carbohydrate are similarly circumstanced in connexion with this point. The digestion products of both are rapidly put out of sight after absorption from the alimentary canal, and are not to be traced on into the general circulation. Introduced into the circulation, both are, to a certain extent, susceptible of being dealt with and removed from view, that which is not so dealt with, flowing off, in each case with the urine. Professor E. H. Starling, in a paper published in Vol. XIV. of the *Journal of Physiology*, says with reference to the results obtained from the injection of peptone and sugar into the blood: "It will be seen from them that the behaviour of peptone after injection is almost exactly analogous to that of sugar."

What is it that occurs in connexion with the disappearance of carbohydrate to account for the phenomenon? A portion may be taken by the tissue bioplasmic molecules, if there is a want of it to replace side-chains that have been worked off. Evidence, however, is forthcoming to show that there is to be found within the blood itself a means by which sugar may be carried out of view.

Besides carbohydrate in the form of sugar,

CARBOHYDRATE IN THE AMYLOSE FORM IS OBTAINABLE FROM BLOOD.

After the removal of the sugar by treatment with alcohol, the precipitated matter is capable of yielding a certain amount of carbohydrate in the amylose form, after having been subjected to the breaking-down influence of boiling with potash. This, under ordinary circumstances, is found to amount to about 1 per 1000 of blood. I have for a long time known that the amylose carbohydrate that is thus capable of being obtained from blood, shows itself in greater amount after the introduction of sugar into the circulation. I gave illustrations of this in my "Physiology of the Carbohydrates," published in 1894, and regarded the fact as constituting a noteworthy point.

Later, I recognised that if I introduced sugar into the circulation in conjunction with a boiled aqueous extract of pancreas, the amylose carbohydrate was to a decided extent further increased. The experiments on this point are set forth in my "Carbohydrate Metabolism and Diabetes" (p. 71 *et seq.*). It seems to me that, without doubt, the conclusion may be drawn from them that the pancreatic extract supplies something which contributes to the conversion, by t bioplasm existing in the blood, of sugar into amylose carb hydrate. The following supplies an epitome of the resu obtained.

I need not here enter into the question of the mode estimation of the amylose carbohydrate. This matter h been fully referred to in my previous writings, extendi over many years past. Suffice it to say, that, upon t strength of some hundreds of estimations, I consider th confidence may be placed in the trustworthiness of t results yielded by the procedure adopted.

In the first place, 11 determinations are given derive from normal rabbit's blood. The figures for the mean these stand at 1·41 grammes of amylose carbohydrate p 1000 grammes of blood, the maximum figures being 1·55, an the minimum 1·25. The figures, therefore, throughout t list stand very closely together.

In five determinations made from blood collected a varying periods up to 30 minutes after the intravenous injec tion of one gramme per kilogramme bodyweight of dextros dissolved in saline solution, the mean figures were 1·61 pe 1000, the maximum being 1·80, and the minimum 1·52 Two determinations were made after the lapse of an hou from the time of the injection. The figures came out a 1·43 and 1·34, showing that any effect that might have bee previously produced had passed off.

In the case of levulose similarly dealt with, the figures i two experiments from blood collected 15 and 30 minute after the injection were 2·60 per 1000 and 2·67 per 1000 a against 1·81 in one experiment from blood collected at th end of an hour. Looking at these figures, no doubt ca exist of the amylose carbohydrate having been raised by th levulose injection.

Two experiments were made to see the effect of injecting saline solution alone. The figures from blood collected at the end of 15 minutes came out in each case at 1·35 per 1000.

Passing to the experiments with the pancreatic extract, two experiments were conducted in which the extract alone was injected. In one, the blood was collected at the end of 15 minutes, and the figures given were 1·77 per 1000. In the other, the blood was collected at the end of 30 minutes, and the figures given were 1·52 per 1000.

In 13 experiments, the pancreatic extract was employed with 1 gramme per kilogramme bodyweight of dextrose.

whole, there is far less spread of the disease than usually takes place as the cold weather sets in, but it is impossible to say whether this state of things will last.

Health of Prisoners in Indian Jails.

A note by the Sanitary Commissioner with the Government of India on sickness and mortality in jails during the year 1907 has just been issued. It appears that the record of the health of prisoners in Indian jails is one of consistent progress. While the death-rates among the general population are rising those among the prisoners are falling, and although the rates among both classes of people fluctuate from year to year the fluctuations in the jail death-rates are becoming less frequent and less marked. The rates are falling more steadily than formerly, and it is justifiable to say that this is because in the jails the arrangements for counteracting the influences of adverse climatic conditions and for preventing the spread of communicable diseases are improving every year. There is no doubt that at the present time prisoners in Indian jails live under conditions which in nearly all respects are very favourable to health. Cholera and plague, the scourges of the general population, scarcely affect the prison statistics and in preventing the spread of other communicable diseases medical officers have obtained a high degree of success. Although the climatic conditions of 1907 were abnormal and in most provinces were unfavourable to prosperity, which in India is a factor of much importance in connexion with health, the health of the prisoners was good and the death-rate on an average daily population of 107,675 (or 2407 less than in 1906) was only 18·51 per 1000, which is the lowest rate ever recorded. In these figures the statistics in the Andaman Islands (where the average strength was 14.411) are included, but as the convicts in these islands live under conditions which differ considerably from those in Indian prisons it is advisable to consider the statistics separately.

Permanganate of Potassium and Snake-bites.

Good results continue to be gained by the use of permanganate of potassium in cases of snake-bite. Reports from 18 districts in Bengal during last year show that in 198 cases where the treatment was resorted to there were only 23 deaths. In a number of instances the persons bitten were not received in hospital until the fatal symptoms had developed, when the permanganate fails, of course, in its effect. The cases which come under treatment are comparatively few, as the people still believe in their snake charmers, but it is hoped that the efficacy of the new remedy will gradually become known to all classes. It is suggested that as the treatment is very simple and efficacious local governments might well order that every police station and outpost, every school and every president of a *panchayat*, should be provided with permanganate lancets, so that cases of snake-bite may receive the earliest treatment. This is a very practical suggestion; the cost of the lancets would be trifling and the number of cases treated annually would probably rise from hundreds to thousands.

Oct. 30th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Eighth Australasian Medical Congress.

THE Eighth Australasian Medical Congress was formally opened on Monday, Oct. 19th, in the Melbourne Town Hall. His Excellency, Sir T. Gibson-Carmichael, the Victorian State Governor, presided, and the Victorian Government was represented by the Hon. T. Swinburne, Minister of Public Works. The present Congress in point of numbers is larger than any of the previous gatherings, upwards of 750 members being enrolled, and it is estimated that about 500 members will be in actual attendance. The opening ceremony was very imposing. The town hall was filled by a large audience, while the gallery opposite the platform was occupied by nurses in costume, making up a striking picture. After a welcome had been extended by the Governor, Mr. Swinburne, and the Lord Mayor of Melbourne to the visiting members, Professor H. B. Allen delivered his inaugural address as President of the Congress. He dealt first with a review of the mystery of life as exemplified in a study of the bio-chemical processes and the continuity of life. He contrasted the underlying continuity of existence with the tendency to individual variation, and noticed the chief theories of heredity and their possible bearing on medical thought. Passing from the theoretical consideration of life processes to the practical care of life which was the peculiar function of the medical profession, Professor Allen deplored the fact that the death-rate from puerperal sepsis and accidents of childbirth had altered very little during the past 40 years either in England and Wales or in Victoria. He advocated a Midwives Act for Victoria on the lines of the present English Act. He also pointed out the decline of the birth-rate and dwelt on the physical and mental evils of the childless home. The infant mortality figures, however, showed a more cheerful subject for study and Professor Allen dealt with the importance of natural feeding and the need for the control of the milk-supply. He noticed the growing activity of public health administration and drew attention to some notable improvements in the mortality figures of certain infectious disorders. In conclusion he said that the medical profession owed the public "a service of thought as well as a service of action. The members of Congress would go back to their spheres of duty made stronger by fellowship and humbly striving for a more adequate answer to the question, 'What hast thou done, what hast thou thought?'" A vote of thanks was carried on the motion of Dr. J. Thomson (Brisbane) and Professor T. P. Anderson Stuart (Sydney). On Tuesday the address in the Section of Medicine was delivered in the Wilson Hall by Dr. G. E. Rennie of Sydney. His theme was the mental factor in disease and the importance of determining whether there was any organic change at all present in certain patients. He dealt with the apparent causative influence of mental anxiety in such an affection as diabetes as illustrating the importance of the inter-relation between mental states and organic disease. He further examined the mimicry of actual disease by mental states and instanced cases in his own experience which had been cured by reasoning the patient out of the idea that actual disease was present. The importance of thorough examination of every organ was dwelt on before any result could be looked for, but in many of the cases of neurasthenia and psychasthenia and allied states the mental attitude was often too lightly dismissed or even passed over altogether. He noticed the treatment of such conditions by reasoning, suggestion, and hypnotism, expressing distrust of a great deal that had been published in connexion with the last named.

Hospitals for the Insane.

The annual report of the Inspector-General for Victoria shows that there were on Jan. 1st, 1907, 4937 certified insane patients in Victoria. At the end of the year the number had increased to 5052, making 1 in 249 of the population. 219 cases were dismissed from the asylums as complete cures, 68 were relieved, and 16 without benefit. The recovery-rate was the lowest since 1897, but this was partly due to the fact that the cases dealt with at the receiving house were not included in asylum figures. An analysis of the probable cause of insanity in the 728 cases admitted during 1907 showed 169 due to unknown factors, 86 had suffered previous attacks, 64 were attributed to intemperance in drink, 57 to hereditary influence, 42 to mental anxiety, and 32 to domestic trouble. The conduct of the licensed houses was said to be all that could be desired. They could be made more useful by admitting patients on a voluntary boarder system. At Kew Asylum an outbreak of enteric fever occurred in which 61 cases were treated with 14 deaths. "It is a fact worthy of note," says the report, "that eight patients showed marked mental improvement after they had recovered from their illness." The cause of the outbreak has not been traced. It is recommended that the Lunacy Act should be amended so as to provide for the transfer without further certification of patients from the hospitals for the insane to private licensed homes and from the latter to the former. The expenditure for the year was £141,543, an increase of £5315 on the previous year.

Milk-supply of Sydney.

A deputation recently waited on the Lord Mayor in Sydney with reference to the establishment of milk depôts. The Lord Mayor pointed out that the council had no power to take any such action. Dr. W. G. Armstrong, the city health carbohydrate molecule should fail to become linked on to the bioplasmic molecule, what, it may be asked, would be the state of things produced? The sugar molecule would be left untouched, and would thence pass on into the circulation in a free state, which is tantamount to saying that there would be glycosuria proportionate in extent to the carbohydrate ingested and failing to become assimilated.

If the amboceptor is concerned in performing the office suggested in connexion with the appropriation of carbohydrate by incorporation into bioplasm, it may not unreasonably be considered to be similarly concerned in the transmutation of sugar into glycogen in the liver. The passage of sugar into glycogen constitutes a building-up operation. There are grounds for believing that the sugar in the first instance becomes taken into bioplasm. Afterwards, from the redundancy existing, a shedding off in the form of glycogen would follow, in conformity with what is conceived in circumstances of the kind to ordinarily occur. Viewed in this way, the amboceptor, if needed for the bioplasmic assimilative operation, may be reckoned to be also needed for the transmutation of sugar into glycogen in the liver.

Experience in connexion with diabetes points strongly to a fault of the nature here depicted, standing at the foundation of the show of sugar that occurs. In the passage of ingested carbohydrate to its natural destination, a certain chain of events is passed through. A faulty link in the chain, through such a defect as has been spoken of, would suffice to lead to a breakage of action continuity. A faulty cog in the metabolic mechanism is amply sufficient to account for the arrested progress of onward movement that renders itself perceptible through the sugar that comes into, and ought not to come into, view.

The theory of

GLYCOLYSIS, AS ENUNCIATED BY LÉPINE,

appropriately falls in here for consideration. As long as Lépine held to the canons of the glycogenic doctrine, which imply destruction, and thereby disappearance, of sugar in the transit of the blood through the systemic capillaries, there was a show of reason in seeking for an explanation of the disappearance. But how does the matter stand when he retires from his former position and denies the occurrence of the disappearance? This, in reality, is the issue of his recent experimental work, evidence being adduced by him showing the existence of more sugar (instead of less) in the blood returning by the veins than in that contained in the arteries. He, at the same time, speaks of a *virtuel* sugar (which I take to be the same as my combined or locked-up carbohydrate) as a source of the sugar that thus comes into view.

Lépine now endorses what I have all along contended for —namely, that there is not the evidence of sugar being destroyed in its transit through the systemic capillaries that was formerly taken to exist. If such be the case, glycolysis stands upon nugatory ground, and it has always been a mystery to me how a proposition resting upon so inconsistent and illogical a basis should have received the attention that has been given to it.

Even supposing there should be an element of truth contained in the results derived by Lépine from his pancreatic extract and blood incubation experiments, I think a different interpretation can be assigned to them from that which he has given. On the question of validity, the general opinion is that they are open to mistrust, but supposing any loss of sugar to have taken place, may it not have been

THROUGH INCORPORATION INTO BIOPLASM INSTEAD OF THROUGH DESTRUCTION?

He affirms that the leucocytes are mixed up with the action, and likewise that chyle, with its lymphocytes and absence of red corpuscles, possesses greater glycolytic power than blood.

The trend of all modern work is to point to the chemical actions connected with living matter being of an intramolecular nature, and it is difficult to conceive that action occurring outside the living molecule, as Lépine contends for, can constitute the mode of operation. No one thinks of structural formative power being otherwise than associated with the operations of actual living matter. Ought not the chemical phenomena to be viewed in the same way?

Under the assumption of the occurrence of glycolysis in the blood, Otto Cohnheim and others, particularly on the American side of the Atlantic, speak of diabetes being due to sugar failing to be *burnt* in the system. Nothing could be more gratuitous, unfounded, and misleading. There is not a particle of evidence to show that defective oxidising power exists in connexion with diabetes. The real fault is a condition antecedent to the oxidising operation. The food carbohydrate, when permitted to reach the general circulation in the form of free sugar through failing to be assimilated, cannot do otherwise than run off with the urine, and thence escape being placed in a position to undergo oxidation. In the case of the dissociation of sugar from built-up bioplasm in the "composite" type of diabetes, there is no ground for thinking that defective oxygenating power has anything to do with the matter. Whilst the sugar molecule is being thrown off by the operation of a wrong lytic action, oxidisation is proceeding in an ordinary way to permit of life being maintained.

I will now pass on to the consideration of a subject which holds a position of great importance in connexion with diabetes. I have dealt at some length with the incorporation of carbohydrate in the building up of bioplasm, and, under a redundancy, with its dissociation in the form of glycogen as a storage material to be subsequently brought into use when need may arise. As glycogen is of higher construction than the sugar which enters the molecular complex, the transmutation operation must be looked upon as constituting the result of building up.

Dissociation of carbohydrate in another form—that of sugar, occurs in association with

THE PATHOLOGICAL STATE EXISTING IN THE SEVERER KIND OF DIABETES.

To this kind of diabetes I have applied the term "composite," because the eliminated sugar is derived from a twofold source. It comes in part from defective assimilation of the food carbohydrate, and in part from the carbohydrate which has been previously put into combination, and is, from a wrong katabolic action, dissociated.

There must be a flaw of some kind or other in the bioplasmic mechanism to lead to this dissociation of sugar. When the normal katabolic procedure passes on to its proper destination, metabolism proceeds to the attainment of an exhaustion of the latent energy contained in the food-stuff products that are being utilised, and the end-products consist of carbon dioxide, water, and ammonia. In the place of progress to this natural destination, it is found, in the condition being referred to, that the chain of continuity in the bioplasmic mechanism is broken in a manner to lead to the dissociation of sugar. An influence is brought into play which leads to the sugar being broken off from the bioplasmic complex, and, perforce, carrying with it unutilised energy.

This

MOLECULAR DISRUPTION ATTENDED WITH THE DISSOCIATION OF SUGAR

stands, in reality, in the position of a reversed natural action, occurring in place of the line of change that ought to be passed through. The built-up molecule, under the influence of the environment existing, fails to continue functioning in a proper manner, and, instead, undergoes the dissociation observed. As we have already seen, a similar disruption occurs whilst blood impregnated with phloridzin is circulating through the kidney. Away from the kidney, phloridzin exerts no action, but in association with a condition supplied by the kidney structure, it brings about, after the manner of enzymic agency, the severance noticed.

I must here state that, because a certain amount of sugar is being eliminated upon what may be regarded as a properly restricted diet for diabetes, it must not necessarily be taken that the sugar is derived from the wrong breaking-down process being referred to. Meat contains a limited quantity of free carbohydrate. It also contains locked-up carbohydrate in its protein ingredient. From these sources, sugar may pass into the urine in a purely alimentary case of diabetes. If it does, the defect in carbohydrate assimilative power must be of an extreme character and closely border on the next step in which, in addition to the absence of assimilative power, there is a commencing breaking-down of protein in which carbohydrate has been previously locked up.

Facts can be adduced in substantiation of the proposition just set forth. I have now and then observed in cases of diabetes without the coexistence of associated elimination of the acetone series that, after a large quantity of meat taken details of a new hospital in Peking which promised to achieve a far-reaching success in the future. Mr. Daniel M. O'Connor, in proposing the toast of "The Association," roused his audience to great enthusiasm by his whole-hearted advocacy of the claims of Irish medical men and the proceedings terminated after the President had replied.

THE WEST OF ENGLAND EYE INFIRMARY, EXETER.—The committee of the West of England Eye Infirmary has received £2460 towards the £5000 required to erect a new wing which is to be built to celebrate the "centenary" of the institution. It is hoped that the remaining £2540 will shortly be subscribed.

A DINNER was given on Monday, Nov. 23rd, at the Trocadéro Restaurant to Sir Robert W. Burnet, honorary physician to H.R.H. the Prince of Wales, to celebrate the fact that Sir Robert Burnet has been recently knighted. Sir J. Dickson-Poynder, M.P., presided, and among the medical men present were Sir Thomas Barlow and Inspector-General J. Porter, Director-General of the Medical Department of the Royal Navy.

THE MANCHESTER CREMATORIUM.—The nineteenth annual meeting in connexion with the Manchester Crematorium, Limited, was held on Nov. 19th. The report stated that the accounts had been made up to August 31st instead of to Nov. 30th, and in future the financial year would close at the earlier date. There were 83 cremations from Dec. 1st, 1907, to August 31st last, and 1202 since the opening. There was a loss of £3 0s. 6d. on the working during the last nine months. The chairman said that there had been 26 cremations since the end of August, making a total for 11½ months of 109. This he thought compared very favourably with the returns from other towns. It is perhaps worth while to give the numbers from other places that he named. At Golder's Green 315 bodies were cremated during the year; at Sheffield, eight; Leeds, 21; Hull, 32; Bradford, five; Darlington, six; Birmingham, 22; Leicester, 12; Liverpool, 23; Woking, 103; Glasgow, 23; and City of London, 13.

THE INFANTS HOSPITAL.—Post-graduate classes have been started at this institution. They will each consist of six demonstrations to be completed in the course of a fortnight—three in each week, on Tuesdays, Thursdays, and Fridays, from about 4.30 to 6 P.M., the course being practical and clinical. Three of the demonstrations will be conducted in the research laboratory, when each member of the class will be able to carry out the experiments individually. These experiments, connected with the chemistry of milk in its relation to infantile digestion, will be arranged so as to have a direct bearing on the ordering and preparation of foods for infants and the treatment of their nutritional disorders. This practical work is considered to be essential, as by this means the practitioner will be able to obtain that accurate knowledge which can only be obtained from practical work. The remaining demonstrations will be clinical and will deal with the treatment of the diseases and disorders of nutrition, dietetic and otherwise. The classes will be limited by the available laboratory accommodation. All further information can be obtained from Mr. Alfred J. Small, secretary of the hospital, Vincent-square, Westminster, London, S.W.

EPSOM ASYLUMS.—The desirability of Epsom as a residential district has been recently somewhat seriously affected by the protests in the London newspapers against the practice of allowing the inmates of the London County Council asylums to breathe the fresh air of Epsom outside the bounds of the asylums. Matters culminated last week in a public meeting of the inhabitants to consider a proposed motion to compel the London County Council to put a stop to the practice entirely. The Earl of Rosebery took the chair. All the speeches were not well considered, attacks being made on the medical superintendents and others connected with the asylums; but after the chairman of the asylums committee and others had pointed out the desirability from a medical point of view of allowing these ailing parties the motion was lost by a large majority. No doubt the presence of parties of these patients in public may have its disadvantages, but when the improvement in their mental state likely to be derived by the change of air and scene is remembered, the humanity of the Epsom people in not wishing to curtail their privileges under proper supervision is much to be commended. We are certain that all concerned with the management of the asylums are willing to do all that they can to obviate as far as possible any annoyance being caused.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held at the Guildhall, Windsor, on Nov. 26th, when the President, Dr. Francis H. Hawkins of Reading, delivered a presidential address to a large gathering of members. The annual dinner of the society took place at the White Hart Hotel after the meeting, 35 sitting down. Sir R. Douglas Powell, Sir Dyce Duckworth, Sir Thomas Barlow, Dr. F. de Havilland Hall, Dr. Jamieson B. Hurry (President of the Reading Pathological Society), and Mr. V. Warren Low were present, and the Mayor of Windsor, the ex-Mayor, and others were guests of the society on this occasion. In addition to the customary loyal toasts Sir R. Douglas Powell responded for the Royal College of Physicians of London. Sir Dyce Duckworth proposed the health of the society, which was replied to by the President. Mr. W. B. Holderness proposed the medical guests, Sir Thomas Barlow responding; and the Mayor of Windsor returned thanks on behalf of the visitors, which toast was proposed by Dr. E. S. Norris. An excellent *menu* was served and the evening proved a most enjoyable one.

DEATH OF A MEDICAL MAN FROM COCAINE POISONING.—On Nov. 17th, at the Durham County Hospital, an inquest was held on the body of Mr. I. G. Pritchard, M.R.C.S. Eng., L.R.C.P. Lond., aged 30 years. The jury returned a verdict of "Death from cocaine poisoning," there being insufficient evidence to indicate the object of the deceased in taking it. According to the evidence of Mr. Alfred Leeming, a pharmaceutical chemist, the deceased went into his shop and asked for ten grains of cocaine hydrochloride, with one drachm of water, saying that it was for a patient. When he was making up the prescription he noticed that the deceased was "shaky," and asked him if he would like to go upstairs and rest. Witness assisted Mr. Pritchard up the stairs into a room and left him for a few minutes. On returning he became alarmed at his condition and sent for Dr. Smith. The deceased was removed to the hospital and died about two and a half hours afterwards. Dr. Henry Smith said that a week after Mr. Pritchard had entered his service as an assistant he looked unwell but seemed to have recovered his health on the following morning. He (Dr. Smith) believed that his assistant had contracted the cocaine habit and a bottle of cocaine and a hypodermic syringe were missing from the surgery.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 19th, Dr. F. H. Champneys being in the chair. Letters from a certified midwife as to the exercise by the local supervising authority of its powers of supervision and inspection were further considered. The Board decided that no further action should be taken in the matter, as it appears that the inquiries complained of in the letters were not made by an official supervising authority. A letter was considered from a certified midwife asking the Board to grant her a voucher in place of her certificate, with the possession of which she had parted under an agreement with her employers. The Board decided in the circumstances of the case to decline to grant a voucher. A letter was considered from the clerk of the Derbyshire county council, suggesting that annual licences to practise as a midwife should be granted to suitable women passing a modified examination. The Board decided that no action should be taken in the matter. A letter was considered from the clerk of the Privy Council stating that the Local Government Board had instructed an inspector to inquire into the outbreak of a series of cases of pemphigus occurring in the practice of a midwife in Worcestershire. The Board decided that the clerk of the Privy Council should be thanked for his action in the matter. Letters were considered from Mr. Jordan Lloyd, one of the Board's examiners for the Birmingham centre, as to the duty of an examiner when a candidate is seen to be suffering from ulcerating lupus of the face or other kindred diseases. The Board decided: (1) that Mr. Lloyd should be informed that in the circumstances of the case it is the duty of the examiner to pass the candidate if she satisfies the test and to report specially on carbohydrate molecule should fail to become linked on to the bioplasmic molecule, what, it may be asked, would be the state of things produced? The sugar molecule would be left untouched, and would thence pass on into the circulation in a free state, which is tantamount to saying that there would be glycosuria proportionate in extent to the carbohydrate ingested and failing to become assimilated.

If the amboceptor is concerned in performing the office suggested in connexion with the appropriation of carbohydrate by incorporation into bioplasm, it may not unreasonably be considered to be similarly concerned in the transmutation of sugar into glycogen in the liver. The passage of sugar into glycogen constitutes a building-up operation. There are grounds for believing that the sugar in the first instance becomes taken into bioplasm. Afterwards, from the redundancy existing, a shedding off in the form of glycogen would follow, in conformity with what is conceived in circumstances of the kind to ordinarily occur. Viewed in this way, the amboceptor, if needed for the bioplasmic assimilative operation, may be reckoned to be also needed for the transmutation of sugar into glycogen in the liver.

Experience in connexion with diabetes points strongly to a fault of the nature here depicted, standing at the foundation of the show of sugar that occurs. In the passage of ingested carbohydrate to its natural destination, a certain chain of events is passed through. A faulty link in the chain, through such a defect as has been spoken of, would suffice to lead to a breakage of action continuity. A faulty cog in the metabolic mechanism is amply sufficient to account for the arrested progress of onward movement that renders itself perceptible through the sugar that comes into, and ought not to come into, view.

The theory of

GLYCOLYSIS, AS ENUNCIATED BY LÉPINE,

appropriately falls in here for consideration. As long as Lépine held to the canons of the glycogenic doctrine, which imply destruction, and thereby disappearance, of sugar in the transit of the blood through the systemic capillaries, there was a show of reason in seeking for an explanation of the disappearance. But how does the matter stand when he retires from his former position and denies the occurrence of the disappearance? This, *in reality*, is the issue of his recent experimental work, evidence being adduced by him showing the existence of more sugar (instead of less) in the blood returning by the veins than in that contained in the arteries. He, at the same time, speaks of a *virtuel* sugar (which I take to be the same as my combined or locked-up carbohydrate) as a source of the sugar that thus comes into view.

Lépine now endorses what I have all along contended for —namely, that there is not the evidence of sugar being destroyed in its transit through the systemic capillaries that was formerly taken to exist. If such be the case, glycolysis stands upon nugatory ground, and it has always been a mystery to me how a proposition resting upon so inconsistent and illogical a basis should have received the attention that has been given to it.

Even supposing there should be an element of truth contained in the results derived by Lépine from his pancreatic extract and blood incubation experiments, I think a different interpretation can be assigned to them from that which he has given. On the question of validity, the general opinion is that they are open to mistrust, but supposing any loss of sugar to have taken place, may it not have been

THROUGH INCORPORATION INTO BIOPLASM INSTEAD OF THROUGH DESTRUCTION?

He affirms that the leucocytes are mixed up with the action, and likewise that chyle, with its lymphocytes and absence of red corpuscles, possesses greater glycolytic power than blood.

The trend of all modern work is to point to the chemical actions connected with living matter being of an intramolecular nature, and it is difficult to conceive that action occurring outside the living molecule, as Lépine contends for, can constitute the mode of operation. No one thinks of structural formative power being otherwise than associated with the operations of actual living matter. Ought not the chemical phenomena to be viewed in the same way?

Under the assumption of the occurrence of glycolysis in the blood, Otto Cohnheim and others, particularly on the American side of the Atlantic, speak of diabetes being due to sugar failing to be *burnt* in the system. Nothing could be more gratuitous, unfounded, and misleading. There is not a particle of evidence to show that defective oxidising power exists in connexion with diabetes. The real fault is a condition antecedent to the oxidising operation. The food carbohydrate, when permitted to reach the general circulation in the form of free sugar through failing to be assimilated, cannot do otherwise than run off with the urine, and thence escape being placed in a position to undergo oxidation. In the case of the dissociation of sugar from built-up bioplasm in the "composite" type of diabetes, there is no ground for thinking that defective oxygenating power has anything to do with the matter. Whilst the sugar molecule is being thrown off by the operation of a *wrong lytic action, oxidisation is proceeding* in an ordinary way to permit of life being maintained.

I will now pass on to the consideration of a subject which holds a position of great importance in connexion with diabetes. I have dealt at some length with the incorporation of carbohydrate in the building up of bioplasm, and, under a redundancy, with its dissociation in the form of glycogen as a storage material to be subsequently brought into use when need may arise. As glycogen is of higher construction than the sugar which enters the molecular complex, the transmutation operation must be looked upon as constituting the result of building up.

Dissociation of carbohydrate in another form—that of sugar, occurs in association with

THE PATHOLOGICAL STATE EXISTING IN THE SEVERER KIND OF DIABETES.

To this kind of diabetes I have applied the term "composite," because the eliminated sugar is derived from a twofold source. It comes in part from defective assimilation of the food carbohydrate, and in part from the carbohydrate which has been previously put into combination, and is, from a wrong katabolic action, dissociated.

There must be a flaw of some kind or other in the bioplasmic mechanism to lead to this dissociation of sugar. When the normal katabolic procedure passes on to its proper destination, metabolism proceeds to the attainment of an exhaustion of the latent energy contained in the food-stuff products that are being utilised, and the end-products consist *of carbon dioxide, water, and ammonia*. In the place of progress to this natural destination, it is found, in the condition being referred to, that the chain of continuity in the bioplasmic mechanism is broken in a manner to lead to the dissociation of sugar. An influence is brought into play which leads to the sugar being broken off from the bioplasmic complex, and, perforce, carrying with it unutilised energy.

This

MOLECULAR DISRUPTION ATTENDED WITH THE DISSOCIATION OF SUGAR

stands, in reality, in the position of a reversed natural action, occurring in place of the line of change that ought to be passed through. The built-up molecule, under the influence of the environment existing, fails to continue functioning in a proper manner, and, instead, undergoes the dissociation observed. As we have already seen, a similar disruption occurs whilst blood impregnated with phloridzin is circulating through the kidney. *Away from* the kidney, phloridzin exerts no action, but in association with a condition supplied by the kidney structure, it brings about, after the manner of enzymic agency, the severance noticed.

I must here state that, because a *certain amount of sugar* is being eliminated upon what may be regarded as a properly restricted diet for diabetes, it must not necessarily be taken that the sugar is derived from the wrong breaking-down process being referred to. Meat contains a limited quantity of free carbohydrate. It also contains locked-up carbohydrate in its protein ingredient. From these sources, sugar may pass into the urine in a purely alimentary case of diabetes. If it does, the *defect in* carbohydrate assimilative power must be of an extreme character and closely border on the next step in which, in addition to the absence of assimilative power, there is a commencing breaking-down of protein in which carbohydrate has been previously locked up.

Facts can be adduced in substantiation of the proposition just set forth. I have now and then observed in cases of diabetes without the coexistence of associated elimination of the acetone series that, after a large quantity of meat taken details of a new hospital in Peking which promised to achieve a far-reaching success in the future. Mr. Daniel M. O'Connor, in proposing the toast of "The Association," roused his audience to great enthusiasm by his whole-hearted advocacy of the claims of Irish medical men and the proceedings terminated after the President had replied.

THE WEST OF ENGLAND EYE INFIRMARY, EXETER.—The committee of the West of England Eye Infirmary has received £2460 towards the £3000 required to erect a new wing which is to be built to celebrate the "centenary" of the institution. It is hoped that the remaining £540 will shortly be subscribed.

A DINNER was given on Monday, Nov. 23rd, at the Trocadéro Restaurant to Sir Robert W. Burnet, honorary physician to H.R.H. the Prince of Wales, to celebrate the fact that Sir Robert Burnet has been recently knighted. Sir J. Dickson-Poynder, M.P., presided, and among the medical men present were Sir Thomas Barlow and Inspector-General J. Porter, Director-General of the Medical Department of the Royal Navy.

THE MANCHESTER CREMATORIUM.—The nineteenth annual meeting in connexion with the Manchester Crematorium, Limited, was held on Nov. 19th. The report stated that the accounts had been made up to August 31st instead of to Nov. 30th, and in future the financial year would close at the earlier date. There were 83 cremations from Dec. 1st, 1907, to August 31st last, and 1202 since the opening. There was a loss of £3 0*s.* 6*d.* on the working during the last nine months. The chairman said that there had been 26 cremations since the end of August, making a total for 11½ months of 109. This he thought compared very favourably with the returns from other towns. It is perhaps worth while to give the numbers from other places that he named. At Golder's Green 315 bodies were cremated during the year; at Sheffield, eight; Leeds, 21; Hull, 32; Bradford, five; Darlington, six; Birmingham, 22; Leicester, 12; Liverpool, 23; Woking, 108; Glasgow, 23; and City of London, 13.

THE INFANTS HOSPITAL.—Post-graduate classes have been started at this institution. They will each consist of six demonstrations to be completed in the course of a fortnight—three in each week, on Tuesdays, Thursdays, and Fridays, from about 4.30 to 6 P.M., the course being practical and clinical. Three of the demonstrations will be conducted in the research laboratory, when each member of the class will be able to carry out the experiments individually. These experiments, connected with the chemistry of milk in its relation to infantile digestion, will be arranged so as to have a direct bearing on the ordering and preparation of foods for infants and the treatment of their nutritional disorders. This practical work is considered to be essential, as by this means the practitioner will be able to obtain that accurate knowledge which can only be obtained from practical work. The remaining demonstrations will be clinical and will deal with the treatment of the diseases and disorders of nutrition, dietetic and otherwise. The classes will be limited by the available laboratory accommodation. All further information can be obtained from Mr. Alfred J. Small, secretary of the hospital, Vincent-square, Westminster, London, S.W.

EPSOM ASYLUMS.—The desirability of Epsom as a residential district has been recently somewhat seriously affected by the protests in the London newspapers against the practice of allowing the inmates of the London County Council asylums to breathe the fresh air of Epsom outside the bounds of the asylums. Matters culminated last week in a public meeting of the inhabitants to consider a proposed motion to compel the London County Council to put a stop to the practice entirely. The Earl of Rosebery took the chair. All the speeches were not well considered, attacks being made on the medical superintendents and others connected with the asylums; but after the chairman of the asylums committee and others had pointed out the desirability from a medical point of view of allowing these walking parties the motion was lost by a large majority. No doubt the presence of parties of these patients in public may have its disadvantages, but when the improvement in their mental state likely to be derived by the change of air and scene is remembered, the humanity of the Epsom people in not wishing to curtail their privileges under proper supervision is much to be commended. We are certain that all concerned with the management of the asylums are willing to do all that they can to obviate as far as possible any annoyance being caused.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held at the Guildhall, Windsor, on Nov. 26th, when the President, Dr. Francis H. Hawkins of Reading, delivered a presidential address to a large gathering of members. The annual dinner of the society took place at the White Hart Hotel after the meeting, 35 sitting down. Sir R. Douglas Powell, Sir Dyce Duckworth, Sir Thomas Barlow, Dr. F. de Havilland Hall, Dr. Jamieson B. Hurry (President of the Reading Pathological Society), and Mr. V. Warren Low were present, and the Mayor of Windsor, the ex-Mayor, and others were guests of the society on this occasion. In addition to the customary loyal toasts Sir R. Douglas Powell responded for the Royal College of Physicians of London. Sir Dyce Duckworth proposed the health of the society, which was replied to by the President. Mr. W. B. Holderness proposed the medical guests, Sir Thomas Barlow responding; and the Mayor of Windsor returned thanks on behalf of the visitors, which toast was proposed by Dr. E. S. Norris. An excellent *menu* was served and the evening proved a most enjoyable one.

DEATH OF A MEDICAL MAN FROM COCAINE POISONING.—On Nov. 17th, at the Durham County Hospital, an inquest was held on the body of Mr. I. G. Pritchard, M.R.C.S. Eng., L.R.C.P. Lond., aged 30 years. The jury returned a verdict of "Death from cocaine poisoning," there being insufficient evidence to indicate the object of the deceased in taking it. According to the evidence of Mr. Alfred Leeming, a pharmaceutical chemist, the deceased went into his shop and asked for ten grains of cocaine hydrochloride, with one drachm of water, saying that it was for a patient. When he was making up the prescription he noticed that the deceased was "shaky," and asked him if he would like to go upstairs and rest. Witness assisted Mr. Pritchard up the stairs into a room and left him for a few minutes. On returning he became alarmed at his condition and sent for Dr. Smith. The deceased was removed to the hospital and died about two and a half hours afterwards. Dr. Henry Smith said that a week after Mr. Pritchard had entered his service as an assistant he looked unwell but seemed to have recovered his health on the following morning. He (Dr. Smith) believed that his assistant had contracted the cocaine habit and a bottle of cocaine and a hypodermic syringe were missing from the surgery.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 19th, Dr. F. H. Champneys being in the chair. Letters from a certified midwife as to the exercise by the local supervising authority of its powers of supervision and inspection were further considered. The Board decided that no further action should be taken in the matter, as it appears that the inquiries complained of in the letters were not made by an official supervising authority. A letter was considered from a certified midwife asking the Board to grant her a voucher in place of her certificate, with the possession of which she had parted under an agreement with her employers. The Board decided in the circumstances of the case to decline to grant a voucher. A letter was considered from the clerk of the Derbyshire county council, suggesting that annual licences to practise as a midwife should be granted to suitable women passing a modified examination. The Board decided that no action should be taken in the matter. A letter was considered from the clerk of the Privy Council stating that the Local Government Board had instructed an inspector to inquire into the outbreak of a series of cases of pemphigus occurring in the practice of a midwife in Worcestershire. The Board decided that the clerk of the Privy Council should be thanked for his action in the matter. Letters were considered from Mr. Jordan Lloyd, one of the Board's examiners for the Birmingham centre, as to the duty of an examiner when a candidate is seen to be suffering from ulcerating lupus of the face or other kindred diseases. The Board decided: (1) that Mr. Lloyd should be informed that in the circumstances of the case it is the duty of the examiner to pass the candidate if she satisfies the test and to report specially on belonging to the other side. It is not permissible to conceive that all power of taking on carbon dioxide can be lost. Such a condition is not consistent with the existence of any evidence of life. The question hinges on degree of power, and what is of concern in the matter is the capacity of the blood for drawing off the carbon dioxide from the tissues whilst it is normally traversing the capillaries. There is nothing to show the degree of carbon dioxide tension in the tissues that is detrimental to bioplasmic activity, but I should think it may be taken that the gas, as it is produced, requires at once to be removed.

The agents producing the acidosis are the

β-OXYBUTYRIC AND DIACETIC ACIDS.

The former is the acid started with, and from it the latter is evolved by oxidation, and this, by escape of carbon dioxide, passes into acetone. The bodies are thus linked together into a series, and in speaking of their source, the question resolves itself into that of β-oxybutyric acid.

From chemistry we learn that butyric acid stands as a lower member of the class of fatty acids to the higher members of which belong stearic, palmitic, and oleic acids, components of the fats largely occurring in the human body. In the process of oxidation, it is usually the β carbon atom of the fatty acids which primarily, both inside and outside the living organism, becomes oxidised. By oxidations in the β position, followed by hydrolytic cleavage, descent can be made from a higher to a lower member of the fatty acid series. A succession of these downward steps leads to the formation of butyric acid, which subsequently passes, by oxidation, into β-oxybutyric acid. In this way, the derivation of β-oxybutyric acid from the normally occurring higher fatty acids can intelligibly be accounted for.

Now, such being the chemical position in which oxybutyric acid stands, ought we not to look to fat for its clinical source? Fat has been already spoken of as a constituent of the bioplasmic complex, thereby standing in the same position as carbohydrate. By wrong katabolism, we have seen that sugar is thrown off, and it is only an analogous procedure for the throwing off of oxybutyric acid likewise to occur. Under the existence of a redundancy, fat and glycogen are thrown off as a normal occurrence for storage purposes, and these are both of them principles suitable for storage on account of the non-diffusible property they possess. In the case, on the other hand, of the abnormal dissociations spoken of, in each instance alike the product thrown off is of a diffusible nature and thereby incapable of retention in the system. Hence the elimination of both the sugar and the oxybutyric acid with the urine.

Sugar, under the circumstances, is the result of a faulty molecular breaking down, and must not the same be said of oxybutyric acid? The two seem to stand in a parallel position, carbohydrate in the one case, and fat in the other, being implicated, but not necessarily acted upon by the same specific cause. As to what stands at the foundation of the intramolecular error that is attended with

DISSOCIATION OF OXYBUTYRIC ACID

is beyond us at present to discuss. The fact of the dissociation is a point of the deepest clinical interest, and I will proceed to give consideration to it, setting forth the information that we can claim to be possessed of, that will help us in dealing with the matter as medical practitioners.

It would seem, from the fact that acetone is not absolutely a foreign body in connexion with the normal state, that there must be some subsidiary action normally occurring in the direction of its production. Under certain conditions, the acetone bodies come into more prominent view. Amongst these may be mentioned, starvation and other conditions of a nature to lead to inanition, the exclusion of carbohydrate from the food as by restriction to a flesh and fat diet, and some febrile diseases, especially when occurring in children. In these cases, the bodies in question do not show themselves to a sufficient extent to produce any damaging effect; there is, however, another class of case with associated acidosis to which attention has been recently directed—delayed chloroform poisoning and cyclical or recurrent vomiting in children —where fatal effects as in diabetic coma have been observed to occur.

It is ordinarily in connexion with diabetes that the elimination of the acetone group assumes significance. With no other disease is it in a like manner associated. It had been for a very long time known that the urine and breath of diabetics might possess a peculiar odour, since found to be attributable to acetone, but until the recognition of diacetic acid in the urine by Gerhardt of Berlin in 1865, no idea existed of the intrinsic nature of this associated condition from which such serious consequences may arise in connexion with diabetes. Although the cleavage process that leads to the appearance of the bodies is virtually independent of that which leads to the dissociation of sugar, yet experience shows that some kind of relationship exists between the two. They seem, in other words, to march on in a parallel manner together.

If a case is dealt with in a way to permit of the elimination of a large quantity of sugar, which implies that the system is being subjected to the toxic influence of the sugar traversing it preparatory to elimination, sooner or later the acetone series may be expected to come into view. It is true it may happen, only very rarely have I seen it do so, that through want of proper attention being given to food, a more or less marked amount of sugar may be voided for several years without the acidosis condition becoming developed. At the same time, however, the patient, in the circumstances specified, is not exempt from the supervention of the other ill-effects arising from the toxic action of the sugar in the system, and has to pay the penalty for the injudicious course taken, by becoming the subject of neuritis, gangrene of the toe, carbuncle, cataract or some other concomitant trouble.

There can, I consider, be no doubt that individuality has much to answer for in connexion with the supervention of the

ACIDOSIS CONDITION.

With a sensitive, high-strung nerve organisation, experience leads me to look for a proneness to the appearance of acidosis. In persons of a worrying, restless, dissatisfied nature, its greater liability to show itself gives an increased gravity to this class of case. Perhaps the greater liability to show itself depends upon the nature alluded to constituting an unfavourable factor in connexion with the progress of the disease itself. In children, it is ordinary for it to set in close to the onset of the disease, and for it soon to assume a more or less pronounced character. Moreover, in children it does not usually disappear during the time the sugar is susceptible of removal by dieting, as it may do in the adult.

I have already stated that, apart from diabetes, the acidosis condition is susceptible of being evoked by, amongst other causes, absence of food. Deprivation of carbohydrate alone suffices to act in a similar way. Now, food is found to constitute an influencing factor on the elimination of the acetone bodies in the diabetic, and it here stands in a position to be invested with bearings of the deepest importance. According to the reading adopted of the results producible by food on the acetone bodies in diabetes, the medical practitioner may be conducted along a right or a wrong path in the treatment of the disease. In the interests of medical art, and, through it, of the patient, the subject therefore demands consideration of the broadest, the most substantially grounded, and the most judiciously weighed nature, that can be brought to bear upon it.

Experience shows that the acidosis which occurs in connexion with diabetes is influenced in the manner I will proceed to speak of by the

EFFECT OF THE RESTRICTION FROM CARBOHYDRATE FOOD

which is put into force in bringing down the sugar in the treatment of the disease. I have been in the habit, for several years past, of having the urine examined for the acetone series in all cases as a part of the examination conducted. The routine plan has been to look for diacetic acid, and this, in a multitude of instances, has been supplemented by looking also for acetone, and, in many instances, likewise for oxybutyric acid. In this way, some thousands of reports upon the point have passed under my notice, and when a positive result has been obtained, a measure of quantity has been inserted by + signs ranging from one up to five or six. It is upon this evidence that what I am about to state is founded.

As a preliminary, it must be mentioned that what is comprised under the term "restricted" diet has a very varied meaning. In reality it should mean the exclusion of carbohydrate as far as can be practically done, and this implies that the substitute for bread-stuff employed should be virtually, and not merely nominally, free from starch.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Children Bill.

THE Children Bill has passed through all its stages in the House of Lords. The assent of the Commons has still to be obtained for the amendments which have been introduced into it in the Upper House.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 25TH.

Education Authorities and Medical Inspection.

Mr. ASHLEY asked the President of the Board of Education whether the Board had taken upon itself under Section 13 (1) (b) of the Education (Administrative Provisions) Act, 1907, the task of deciding the relative status of educational and medical officers employed and paid by local education authorities.—Mr. RUNCIMAN replied: I am not sure what the honourable Member means but I am not aware of any decisions of the Board to which his description would apply.

Mr. ASHLEY further asked the same right honourable gentleman whether, as stated on p. 4 of the Board of Education Circular 576, relating to medical inspection, it was the duty of the Board, under the Education (Administrative Provisions) Act, to give directions to local education authorities regarding the method of inspection; and, if not, whether he would withdraw the circular so giving directions.—Mr. RUNCIMAN answered: The Circular No. 576 was obviously of a preliminary character as it was issued on Nov. 22nd, 1907. It was certainly the duty of the Board not to leave local education authorities without such advice and guidance in the initiation of the work of medical inspection as in the Board's opinion would conduce to efficiency and economy, and such advice and guidance have, in fact, been heartily welcomed by the local education authorities and their officers with a very few exceptions throughout the country. The question of enforcing the circular has not arisen, and, indeed, cannot arise.

Mr. ASHLEY also asked the right honourable gentleman whether the last three lines of page 8 of the Board of Education Circular 576 were the only part of that circular which it was not *ultra vires* for the Board to promulgate or to enforce; and whether, as stated on page 11, that circular was of a preliminary nature only.—Mr. RUNCIMAN said in reply: I do not think the circular can be properly described as in fact giving directions outside the Board's competence. The whole of the circular, (as was stated in paragraph 18, was of a preliminary nature only. The matter is now dealt with definitely in the code.

THURSDAY, NOV. 26TH.

Deaths in an Irish Orphanage.

Mr. MACCAW asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the circumstances attending the death of nine inmates of the Mount St. Vincent Orphanage at Limerick and the illness of 44 others, as the result of eating meat which had been kept five day [illegible] ked; whether this orphanage recei [illegible] ether it was inspected on behalf of [illegible] was intended to take any action [illegible] and lives of the inmates of this [illegible] RELL replied: My attention has been called to this case. The institution is [illegible] pitation grant from the [illegible] It also receives contri- [illegible] as always been regarded [illegible] eland. This unfortunate occurrence was a misadventure which might have happened anywhere and is deeply regretted by the managers of the school.

Deaths under Anæsthetics.

Mr. COOPER asked the Secretary of State for the Home Department whether his attention had been drawn to an inquest held on a boy named Alfred Lebathe, aged 12 years, who died at the Metropolitan Hospital during the administration of an anæsthetic and before an operation was commenced; and whether he had had any answer to his communication with the General Medical Council as to the advisability of in future [illegible] of anæsthetics should form a part of [illegible] dent. Mr. COOPER further asked the [illegible] her his attention had been called to [illegible] roner for the City of London that only [illegible] curring under anæsthesia in private [illegible] he registrar or coroner; whether the [illegible] neral showed that an average of three [illegible] of an anæsthetic occurred in the hospitals of England and Wales each week; and whether he would consider the advisability of appointing either a commission or making a grant to the Royal Society and asking that society to appoint a committee to inquire into all the facts of deaths under anæsthesia, and to advise generally as to the conditions to be observed and regulations to be carried out when an anæsthetic was administered.—Mr. GLADSTONE (by written answer) replied: I will answer both questions together. My attention has been drawn to several statements on this subject, including that of the coroner for the City of London, to the figures in the Registrar-General's report, and to many cases of inquests on persons who have died under anæsthetics. The Lord President of the Council, through whom I communicated with the General Medical Council, informs me that he understands a reply may be expected in a very few days from that body which is now in session. As I have stated before, the question of holding a formal inquiry must be postponed, at any rate till I know what action the medical authorities are prepared to take.[1]

Beri-beri on Merchant Ships.

Mr. COOPER asked the President of the Board of Trade whether he had received the report of the Special Committee of the Royal College of Physicians on the subject of beri-beri on merchant ships, and, if so, when it would be published.—Sir HUDSON KEARLEY (the Parliamentary Secretary to the Board of Trade) furnished t [illegible] A report by the Committee of the Royal Col [illegible] beri has been received, but it contains no [illegible] the subject and the Board of Trade does not propose [illegible] Committee suggested that a Commission which is at present at work at Kuala Lumpur on the subject of Beri-beri might throw some light on the matter and the Board of Trade is awaiting the report of that Commission.

MONDAY, NOV. 30TH.

The Sanitary Condition of Barracks.

Mr. ASHLEY asked the Secretary of State for War whether he would grant a return showing the barracks in the United Kingdom which were reported by the Army Medical Department to be in an indifferent sanitary state, as judged by modern standards.—Mr. HALDANE replied: It is quite obvious that owing to the date of the construction of the barracks many of our buildings must necessarily fall short of what is considered desirable in these days. I am not prepared to admit that any of them are in a dangerous condition and I cannot agree that the return asked for should be compiled.

Notification of Pauper Consumptives.

Mr. VIVIAN asked the President of the Local Government Board whether he could see his way in the proposed legislation for making compulsory the notification of consumption in the case of paupers to extend the proposal of compulsory notification to all cases of consumption.—Mr. BURNS answered: I do not contemplate legislation on this subject at the present time. The action I propose to take as regards the notification of consumption in Poor-law cases will be taken under the existing powers of the Local Government Board and must, I think, be limited to such cases.

TUESDAY, DEC. 1ST.

Malarial Fever in India.

Mr. REES asked the Under Secreta [illegible] malarial fever prevailed to an abnorm [illegible] parts of Bengal and Bombay; and if so, [illegible] taken by the Government of India to [illegible] epidemic.—Mr. BUCHANAN answered: Malarial fever has been exceptionally prevalent in the United Provinces and the Punjab, and to a less extent in Bombay, and has affected both the European and Indian population. The epidemic began in October last and a telegram received this morning reports it to be rapidly declining. To combat the disease [illegible] has been largely distributed free of charge, travelling dispensari [illegible] places much attention has been paid [illegible] The causation of the disease is under investigation [illegible] medical staff.

White Phosphorus and Necrosis.

The Earl of RONALDSHAY asked the Secretary of State for the Home Department how many manufacturers in this country employed white phosphorus in the manufacture of matches; and how many cases of necrosis there had been in each such factory in each of the last five years.—Mr. GLADSTONE said in reply: There are ten firms using white phosphorus in the manufacture of matches. One firm has had five cases of necrosis during the last five years; the other firms have had none. This result has only been attained by means of an elaborate and costly system of regulation. Moreover, as intimated in the memorandum prefixed to the Bill now before the House, recent events have shown that the existing regulations are insufficient to remove entirely the risk of necrosis, and that even more stringent regulations would be required if the use of white phosphorus were to be continued..

WEDNESDAY, DEC. 2ND.

The Inspection of Fever Hospitals.

Mr. WATT asked the President of the Local Government Board whether any independent inspection was made by his department of [illegible] ublic corporations; and if not, would he [illegible] instituted, in view of the fact that the [illegible] ortunity of judging of these than in the case of general hospitals.—Mr. BURNS replied: A fever hospital provided by a local authority would not be inspected by a medical inspector of the Local Government Board in the ordinary course. The responsibility for the proper administration of such a hospital rests with the local authority, though in some instances where there has been a complaint of mal-administration the Board have caused an investigation to be made. Moreover, where the district of a sanitary authority is inspected by a medical inspector he would include the hospital of the authority in his inspection. It does not seem to me necessary that any change should be made in the practice in this matter.

Mr. WATT: Arising out of that answer, may I ask whether my right honourable friend is aware that a number of these fever hospitals have in late months been found in a very unsatisfactory condition?

Mr. BURNS: If my honourable friend, or anyone else, will give me the instances I shall be pleased to break through the ordinary rule and send medical inspectors to look into matters.

HOUSING AND TOWN PLANNING BILL.

County Medical Officers.

Standing Committee "B" of the House of Commons had under consideration on Wednesday, Nov. 25th, Part III. of the Housing and Town Planning Bill, which deals with the appointment of county medical officers. Sir F. CHANNING presided. The first of the clauses imposes the duty on every county council to appoint a medical officer of health under Section 17 of the Local Government Act, 1888.

Sir F. POWELL moved an amendment to provide that the officer should not be removeable except by, and with the consent of, the Local Government Board.

Mr. BURNS could not agree to the amendment but he would accept certain amendments standing in the name of Sir John Dickson-Poynder. These were: "(1) A medical officer of health for the county shall be removeable by the county council with the consent of the Local Government Board, and not otherwise. (2) Any such medical officer shall not be appointed for a limited period only. (3) A medical officer of health appointed under this section shall not engage in private practice and shall not hold any other public appointment by the food principles—namely, that they became elaborated into chyle, which served as a feeder to the blood. It is only in more recent years, as I have previously notified, that the shunting on to a wrong track has occurred, and that, notwithstanding chyle so obviously consists of elaborated food, the food principles have been looked upon as reaching the circulation in an uncombined, small molecular state, for transmission in such state to the tissues.

---

[1] See THE LANCET (current issue), p. 1682.

The view I am advocating not only fits in consistently from beginning to end with what I take to be properly read physiological considerations, but supplies a working basis for the treatment of diabetes which places us upon perfectly intelligible ground. It provides for the occurrence of assimilative action preparatory to the circulation being reached, and thereby for conveyance in an assimilated state to the seat of utilisation. Thus circumstanced, the digested food products are not in a condition to run off with the urine in traversing the kidney, but stand in the blood as a retainable reserve, ready to be drawn upon by the tissues as need may arise.

To mal-assimilation of carbohydrate food is to be assigned the error existing in diabetes, and what is wanted to be effected by treatment is

RESTORATION OF THE DEFECTIVE ASSIMILATIVE POWER.

Restore this power, and the patient will be no longer diabetic. Assimilative power being restored, he will then be able to take carbohydrate, and this, meeting with the power to assimilate it, will no longer pass through the system as sugar to be thrown out as waste material with the urine.

Restoration of carbohydrate assimilative power, then, is the goal of the medical practitioner in the treatment of diabetes. For the attainment of his object, it may without hesitation be said that food is the prime factor to be brought into play. Sugar in the system is the baneful agent, and unless this is brought down, no real good can be expected to arrive. The toxicity of the sugar will nullify every other effort. If the sugar can be reduced and removed, the foundation is laid for the desired restoration of assimilative power, whilst in the absence of its reduction, the condition, with varying degrees of rapidity in different cases, may be reckoned upon to grow worse and worse.

This being found from practical experience to be the case, any hypothesis which encourages the idea that it is a natural condition for free sugar to be reaching the circulatory system from carbohydrate food acts detrimentally to the interests of the art of medicine by suggesting the absence of the need for putting into force the one measure that the circumstances show to be essential for beneficial treatment. Upon these premises, the medical practitioner has ground for exclaiming against the misguiding influence derived from his physiological training. But physiologists see nothing of the testing of the truth of their teaching that is afforded by the application of endeavours to correct the physiological error constituting the source of diabetes, and they thereby are shut off from the enlightenment contributed by practical medical experience.

It will be seen that under this view the error is located in the first link of the metabolic chain instead of the last, which is assigned as its seat under the glycogenic doctrine. There is absolutely nothing to lend support to the view that the fault in diabetes (the simple or alimentary form of it) consists of a non-consumption of carbohydrate, except in so far as consumption is prevented by exit in the form of sugar with the urine in consequence of being permitted to enter the circulation as free sugar.

With faulty assimilation, as represented, at the foundation of diabetes, it is perfectly intelligible how it is that sugar finds its way into the urine from the food. From the principle of action involved, it is also explicable how the blood and urine under normal conditions remain unaffected, in relation to sugar content, in the face of the very varying quantities of carbohydrate ingested. Under all circumstances, alike in health and diabetes, as long as the carbohydrate taken is within the assimilative power existing, it becomes assimilated, and thence fails to reach the blood and urine as sugar, whilst should it surpass in amount the power existing to assimilate it, that which is not assimilated will find its way as sugar into both blood and urine.

This harmonises with what is observed in cases of diabetes in which the curtailment of carbohydrate tolerating power is susceptible of being displayed—that is, in the alimentary type of the disease. Experience tells us that varied extents of tolerating capacity are found to exist and that they are associated with a very sharp boundary line. The ingestion of carbohydrate within a given quantity fails to produce any visible effect, whilst if the given quantity is exceeded by ever so little, sugar is discoverable in the urine in proportion to the extent to which the line has been overstepped. It is easy to understand that there may be a definitely limited assimilative power—indeed, there is a definite limit to the assimilative power existing in the healthy state—and that whilst the power that exists surpasses that required for the work to be performed, there will be no show of anything wrong, whereas if the work to be performed—the amount of carbohydrate to be assimilated—should exceed the power to perform it, the effect will be that the work which escapes being performed will render itself manifest by the unassimilated carbohydrate passing into the circulation as sugar, and thence flowing off with the urine.

Regarded in this way our position in relation to the management of diabetes becomes one of great clearness and simplicity. We know precisely the ground upon which we stand, and can shape our measures into form with great definiteness to bring about a desired result. How, on the other hand, does the matter stand under the supposition that it is natural for the food carbohydrate to traverse the circulation in the form of sugar? Not the slightest relationship is discoverable between the proposition and the working result obtained. Whatever may be effected by the measure adopted, no rational explanation applicable to it can be educed from the proposition.

Restoration of carbohydrate assimilative power is, as I have said, the great object to be attained in the treatment of diabetes and, as I have further said, for the attainment of this object, it is necessary to reduce and remove, by dietetic measures, the sugar which is acting perniciously in traversing the system. The primary effect of the removal of sugar from the urine is to bring back health and strength to the patient. Virtually, as long as the urine is maintained in a sugar-free state, there is nothing to exert a damaging influence upon the system, and the only perceptible difference existing between a patient in this state and a healthy person is the different effect arising from partaking of carbohydrate food. Only when such food is taken beyond the power existing to assimilate it does the patient betray the existence of anything wrong.

Restoration of health is something for the patient to be thankful for, but this is by no means all that the removal of sugar from the urine by proper dieting effects. By maintaining a sugar-free state of urine—in other words, by maintaining a normal state of things within the system,—Nature steps in and starts mending what is wrong by reinstating the lost assimilative power. In this way there occurs a reversal of what happens whilst sugar is pervading the system, for here there is an advancing loss taking place, as is testified by the progressive growth of a case previous to the disease being recognised and dietetic treatment adopted. At first the condition may be mild, so much so as not to excite attention, when it may be taken that a considerable amount of assimilative power exists, and then, with the growth of the symptoms, a fall of power must obviously be taking place.

When a case falls under observation, everything depends, with respect to capacity for and

SPEEDINESS OF RESTORATION OF ASSIMILATIVE POWER,

upon the extent to which the disease has become developed. If only of recent onset, a few days may suffice for the removal of the sugar, and, shortly after, for signs to present themselves of returning power; whilst if the disease has, through faulty management, been allowed to run on into the development of a thoroughly established condition associated with marked acidosis, the prospect is a poor one of being able to bring about the requisite control of sugar elimination to permit of anything otherwise than continued progress in a wrong direction being looked for. The presence of acidosis is not by any means, it may be said, to be regarded as a bar to subsequent satisfactory progress. It is the point to which it has advanced that determines the issue. I have known cases where more or less return of assimilative power has occurred notwithstanding a considerable amount of acidosis has existed to start upon.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—House Surgeon. Salary £80 per annum, with board and residence.
LONDON TEMPERANCE HOSPITAL.—Assistant House Surgeon, non resident, for six months. Salary at rate of £75 per annum.
LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £100 per annum, with rooms, attendance, board, and washing.
MANCHESTER ROYAL INFIRMARY.—Medical Officer for six months. Salary at rate of £100 per annum, with board and residence.
MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Third and Fourth House Surgeons for six months. Salaries £55, with board and residence.
MEDICAL MISSION HOSPITAL SETTLEMENT OF WOMEN WORKERS, Canning Town.—Assistant Doctor (female) for six months. Board, residence, and laundry.
MIDDLESEX HOSPITAL, W.—Medical Registrar, Surgical Registrar, and Obstetrical Registrar.
NORTHAMPTON GENERAL HOSPITAL.—Senior Resident Medical Officer, unmarried. Salary £120 per annum, with apartments, board, washing, and attendance.
NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon (female) for six months. Salary at rate of £50 per annum, with board, &c.
NOTTINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Also Assistant. Salary of former £180 per annum, and of latter £150 per annum, with apartments, attendance, light, &c., in both cases.
NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £80 per annum, with board, lodging, and washing.
PERTH *DISTRICT* ASYLUM, Murthly.—Assistant Medical Officer. Salary £110 per annum, with rooms, board, and washing.
PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and washing.
POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Radiographer
PRESTON ROYAL INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, &c.
PRESTWICH UNION.—Medical Officer and Assistant Medical Officer. Salary of former £150 per annum, and of latter £140 per annum, with apartments, rations, &c.
ROYAL EAR HOSPITAL, Soho.—House Surgeon for six months. Salary at rate of £40 per annum.
ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.
ST. LUKE'S HOSPITAL FOR MENTAL DISEASES, Old-street, London.—Clinical Assistant, unmarried, for six months.
SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary at rate of £50 per annum, with board and residence.
SHEFFIELD, JESSOP HOSPITAL FOR WOMEN.—House Surgeon, unmarried. Salary £80 per annum, with board and residence.
SOMERSET, WILLITON UNION.—Medical Officer for the Urban Parish of Watchet. Salary £22 10s. per annum, with fees. Also Medical Officer for the Williton District of the Union. Salary £55 per annum, with fees.
SWANSEA GENERAL AND EYE HOSPITAL.—House Surgeon. Salary £75 per annum.
THROAT HOSPITAL, Golden-square, W.—Assistant Surgeons.
WESTMINSTER GENERAL DISPENSARY.—Honorary Surgeon.
WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Assistant Surgeon.
WEST RIDING OF YORKSHIRE.—Assistant Medical Officer. Salary £350 per annum, rising to £400.
WORCESTERSHIRE OPEN-AIR SANATORIUM, Knightwick.—Medical Officer and Wife. Joint salary £150 per annum, with board and house.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act for Paddington and Marylebone, and for St. Pancras and Islington in the county of London, and for Rothwell in the county of Northampton.

Births, Marriages, and Deaths.

BIRTHS.

BARTON.—On Nov. 27th, at Lingfield-road, Wimbledon, the wife of P. F. Barton, M.A., M.B., B.C., of a daughter.
BLACK.—On Dec. 1st, at The Willows, Hailsham, Sussex, the wife of George Black, M.B., B.S. Lond., of a son.
GREENWOOD PENNY.—On Nov. 28th, at Marazion, Cornwall, the wife of S. Greenwood Penny, M.R.C.S., of a son.
HENRY.—On Nov. 27th, at Tresco, Kennington-road, S.E., the wife of G. Noel Henry, M.B., C.M., of a son.
HERDMAN.—On Nov. 22nd, at 3, Foxhill-gardens, Norwood, the wife of Dr. Ronald Herdman, of a daughter.
MILWARD.—On Nov. 28th, at Botton Park-road, Edgbaston, the wife of F. Victor Milward, M.B., F.R.C.S., of a daughter.

MARRIAGES.

FENOULHET—CAPON.—On Nov. 4th, at the Cathedral, Rangoon, Burma, Andrew Edward Colin (late Captain, 3rd Battalion, Royal Berkshire Regiment), elder son of Dr. E. C. Fenoulhet, J.P., and Mrs. Fenoulhet, Herne Bay, Kent, to Mary Elfrida Blanche ("Elsie"), elder daughter of Dr. and Mrs. Herbert J. Capon, of 43, Upper George-street, Bryanston-square, W.

DEATHS.

COLMAN.—On Nov. 18th, Walter T. Colman, M.R.C.S., L.S.A.
ELLISTON.—On Nov. 27th, at Southorne House, Felixstowe, William Alfred Elliston, M.D., J.P., in his 68th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DISEASES IN SOMALILAND.

IN his report on the Somaliland Protectorate for the year ended March 31st, 1908, the Commissioner, Captain H. E. S. Cordeaux, C.B., C.M.G., mentions that the periods when sickness is chiefly prevalent are the spring and autumn, in consequence mainly of the lack of wool clothing among the natives, who use cotton almost exclusively, with a blanket at night when they can get it. The experience of the last three years has been that it is impossible to provide blankets for the hospital patients, as they are invariably smuggled out and sold. A considerable degree of care is called for in preventing the importation of infectious diseases, both from the interior of Africa generally and from Abyssinia in particular. The rice ports of India and the date-exporting centres along the Persian Gulf have also to be watched in this respect. The native Somali is essentially temperate and seems naturally liable to few diseases. When ill they, as a race, are inclined to disregard the matter. To travel from the locality where they happen to be at the time is looked upon as a universal panacea. Returns from the united coast hospitals show that malaria is on the increase, the cases recorded having been nine in 1904, 117 in 1905, 539 in 1906, and 751 in 1907. The causes leading to this condition of affairs are: (1) the increase of vegetation in the neighbourhood of the dwelling houses; (2) the existing unsatisfactory drainage system; and (3) the lack of measures to prevent the natives from digging or using wells in the native part of the towns. The number of cases of dysentery in 1907 was 135, as against 62 in the previous year, but all were of a very mild type. There were three cases of beri-beri in the local gaol. Scabies was almost epidemic during the year. The number of cases of syphilis presented for treatment was only 77. This figure is particularly misleading in estimating the prevalence of the disease. As a matter of fact, it increased very greatly during the year, but usually only the very advanced cases present themselves for treatment and those who are also very poor. The reason for this is that all who can afford to do so journey to a small spot on the Arabian coast named Sheikh Mohil, situated about a day and a half marching from Mocha, which is the usual landing port for those proceeding to the place. The treatment at Sheikh Mohil is conducted on the water-cure principle. The water is drunk on the first day or so; afterwards the treatment is chiefly confined to bathing frequently. The patients are allowed goats' meat and milk, sweet oil and rice, and two ounces of dates when the cure has shown signs of progressing favourably. The following articles of diet are not allowed—viz., meat or milk of camel, sheep, or cow. This point is considered worth recording, as very unusual and speedy cures have come under notice. During the year 65 cases of tuberculous disease were treated, with 12 deaths. The climate of the protectorate is a naturally dry and uniform one. Both the diurnal variations and the changes of the seasons maintain a regularity of mean variation that is remarkable. There are two distinct seasons—the hot, from May to September, when the coast belt becomes true desert, and the cool, from October to April. There are two ranges of temperature. These maintain a pretty uniform relation one to the other. The coast range of temperature exists over nearly a 50 mile belt inland, reaching to the hills, and is some 10° F. above the second, or highland, temperature.

DEROGATORY.

To the Editor of THE LANCET.

SIR,—The London County Council has a regulation in force to the effect that medical men who lecture on First Aid and Home Nursing must submit a *form at the end of the course signed by themselves and countersigned as being correct* by the "Responsible Teacher." In this form the date of the lectures and the fee claimed are entered. The same form has to be submitted by nurses giving similar instruction. I consider this countersigning of the application is derogatory to medical men (who are appointed by the County Council) and is quite unnecessary. I think the Lecturers should resent it *en masse*.

I am, Sir, yours faithfully,
Nov. 28th, 1908. M.D.

BRANDY SOLD UNDER A FALSE TRADE DESCRIPTION.

AT the Westminster police court recently Edgar Thompson Gideon, a publican, was summoned under the Merchandise Marks Act, 1887, for exposing for sale brandy to which a false description had been applied in the form of a label placed on the bottle bearing three stars, below which was another label with the words, "James Hennessey and Co., Cognac." The defendant had recently given up the public house at which the brandy was exposed for sale, and the excuse put forward was the suggestion that a barman if dishonest would keep up the stock under his charge by such expedients as putting deceptive labels upon bottles containing inferior spirits, and that this had occurred in the case in question. The defendant gave evidence but was unable to explain further than this how the brandy had got into a wrong bottle He was fined £5 with £5 5s. costs. The medicinal use of brandy, which in the case of patients in humble circumstances must usually by the food principles—namely, that they became elaborated into chyle, which served as a feeder to the blood. It is only in more recent years, as I have previously notified, that the shunting on to a wrong track has occurred, and that, notwithstanding chyle so obviously consists of elaborated food, the food principles have been looked upon as reaching the circulation in an uncombined, small molecular state, for transmission in such state to the tissues.

The view I am advocating not only fits in consistently from beginning to end with what I take to be properly read physiological considerations, but supplies a working basis for the treatment of diabetes which places us upon perfectly intelligible ground. It provides for the occurrence of assimilative action preparatory to the circulation being reached, and thereby for conveyance in an assimilated state to the seat of utilisation. Thus circumstanced, the digested food products are not in a condition to run off with the urine in traversing the kidney, but stand in the blood as a retainable reserve, ready to be drawn upon by the tissues as need may arise.

To mal-assimilation of carbohydrate food is to be assigned the error existing in diabetes, and what is wanted to be effected by treatment is

RESTORATION OF THE DEFECTIVE ASSIMILATIVE POWER.

Restore this power, and the patient will be no longer diabetic. Assimilative power being restored, he will then be able to take carbohydrate, and this, meeting with the power to assimilate it, will no longer pass through the system as sugar to be thrown out as waste material with the urine.

Restoration of carbohydrate assimilative power, then, is the goal of the medical practitioner in the treatment of diabetes. For the attainment of his object, it may without hesitation be said that food is the prime factor to be brought into play. Sugar in the system is the baneful agent, and unless this is brought down, no real good can be expected to arrive. The toxicity of the sugar will nullify every other effort. If the sugar can be reduced and removed, the foundation is laid for the desired restoration of assimilative power, whilst in the absence of its reduction, the condition, with varying degrees of rapidity in different cases, may be reckoned upon to grow worse and worse.

This being found from practical experience to be the case, any hypothesis which encourages the idea that it is a natural condition for free sugar to be reaching the circulatory system from carbohydrate food acts detrimentally to the interests of the art of medicine by suggesting the absence of the need for putting into force the one measure that the circumstances show to be essential for beneficial treatment. Upon these premises, the medical practitioner has ground for exclaiming against the misguiding influence derived from his physiological training. But physiologists see nothing of the testing of the truth of their teaching that is afforded by the application of endeavours to correct the physiological error constituting the source of diabetes, and they thereby are shut off from the enlightenment contributed by practical medical experience.

It will be seen that under this view the error is located in the first link of the metabolic chain instead of the last, which is assigned as its seat under the glycogenic doctrine. There is absolutely nothing to lend support to the view that the fault in diabetes (the simple or alimentary form of it) consists of a non-consumption of carbohydrate, except in so far as consumption is prevented by exit in the form of sugar with the urine in consequence of being permitted to enter the circulation as free sugar.

With faulty assimilation, as represented, at the foundation of diabetes, it is perfectly intelligible how it is that sugar finds its way into the urine from the food. From the principle of action involved, it is also explicable how the blood and urine under normal conditions remain unaffected, in relation to sugar content, in the face of the very varying quantities of carbohydrate ingested. Under all circumstances, alike in health and diabetes, as long as the carbohydrate taken is within the assimilative power existing, it becomes assimilated, and thence fails to reach the blood and urine as sugar, whilst should it surpass in amount the power existing to assimilate it, that which is not assimilated will find its way as sugar into both blood and urine.

This harmonises with what is observed in cases of diabetes in which the curtailment of carbohydrate tolerating power is susceptible of being displayed—that is, in the alimentary type of the disease. Experience tells us that varied extents of tolerating capacity are found to exist and that they are associated with a very sharp boundary line. The ingestion of carbohydrate within a given quantity fails to produce any visible effect, whilst if the given quantity is exceeded by ever so little, sugar is discoverable in the urine in proportion to the extent to which the line has been overstepped. It is easy to understand that there may be a definitely limited assimilative power—indeed, there is a definite limit to the assimilative power existing in the healthy state—and that whilst the power that exists surpasses that required for the work to be performed, there will be no show of anything wrong, whereas if the work to be performed—the amount of carbohydrate to be assimilated—should exceed the power to perform it, the effect will be that the work which escapes being performed will render itself manifest by the unassimilated carbohydrate passing into the circulation as sugar, and thence flowing off with the urine.

Regarded in this way our position in relation to the management of diabetes becomes one of great clearness and simplicity. We know precisely the ground upon which we stand, and can shape our measures into form with great definiteness to bring about a desired result. How, on the other hand, does the matter stand under the supposition that it is natural for the food carbohydrate to traverse the circulation in the form of sugar? Not the slightest relationship is discoverable between the proposition and the working result obtained. Whatever may be effected by the measure adopted, no rational explanation applicable to it can be educed from the proposition.

Restoration of carbohydrate assimilative power is, as I have said, the great object to be attained in the treatment of diabetes and, as I have further said, for the attainment of this object, it is necessary to reduce and remove, by dietetic measures, the sugar which is acting perniciously in traversing the system. The primary effect of the removal of sugar from the urine is to bring back health and strength to the patient. Virtually, as long as the urine is maintained in a sugar-free state, there is nothing to exert a damaging influence upon the system, and the only perceptible difference existing between a patient in this state and a healthy person is the different effect arising from partaking of carbohydrate food. Only when such food is taken beyond the power existing to assimilate it does the patient betray the existence of anything wrong.

Restoration of health is something for the patient to be thankful for, but this is by no means all that the removal of sugar from the urine by proper dieting effects. By maintaining a sugar-free state of urine—in other words, by maintaining a normal state of things within the system,—Nature steps in and starts mending what is wrong by reinstating the lost assimilative power. In this way there occurs a reversal of what happens whilst sugar is pervading the system, for here there is an advancing loss taking place, as is testified by the progressive growth of a case previous to the disease being recognised and dietetic treatment adopted. At first the condition may be mild, so much so as not to excite attention, when it may be taken that a considerable amount of assimilative power exists, and then, with the growth of the symptoms, a fall of power must obviously be taking place.

When a case falls under observation, everything depends, with respect to capacity for and

SPEEDINESS OF RESTORATION OF ASSIMILATIVE POWER,

upon the extent to which the disease has become developed. If only of recent onset, a few days may suffice for the removal of the sugar, and, shortly after, for signs to present themselves of returning power; whilst if the disease has, through faulty management, been allowed to run on into the development of a thoroughly established condition associated with marked acidosis, the prospect is a poor one of being able to bring about the requisite control of sugar elimination to permit of anything otherwise than continued progress in a wrong direction being looked for. The presence of acidosis is not by any means, it may be said, to be regarded as a bar to subsequent satisfactory progress. It is the point to which it has advanced that determines the issue. I have known cases where more or less return of assimilative power has occurred notwithstanding a considerable amount of acidosis has existed to start upon.

[illegible] Gt. Ormond-street (9 A.M. and 2 [illegible] 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (12th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—*Birmingham Post, Scientific American, Stafford Sentinel, Manchester Evening News, Glasgow Herald, Hull Morning News, Edinburgh Evening Despatch, Wellingborough News, Morning Advertiser, Daily Telegraph, Liverpool Courier, Sunderland Echo, Doncaster Chronicle. Hartlepool Mail, Keighley News, Kent Messenger, Dublin Times, Belfast Whig, Glasgow Citizen, Leamington Spa Courier, Worcester Journal, &c.*

in myxœdema. This something has not yet been discovered, but science ought sooner or later to place us in a better position than we at present stand in relation to the matter. We, however, know that metabolism is influenced through the instrumentality of the nervous system, and this is suggestive that it may, in connexion with the point under consideration, be likewise open to being influenced in a collateral way by drug agency. I am a strong believer in help being given towards promoting the restoration of carbohydrate assimilative power by the administration of opium and some of its derivatives.

THE AGGLUTINATING POWER IN TUBERCULOUS PATIENTS: SERUM DIAGNOSIS AND SERUM PROGNOSIS.[1]

BY PROFESSOR PAUL COURMONT,
OF THE UNIVERSITY OF LYONS.

THE serum diagnosis of tuberculosis is one of the most commonly employed and most certain of the laboratory methods for the diagnosis of tuberculosis. It is practised, like that of typhoid fever, by mixing the serum of the patient with a certain quantity of liquid homogeneous culture of the bacillus of tuberculosis.

I.—*Historical.*

It is known that the usual culture of the bacillus of Koch cannot be utilised for agglutination. It was Professor Arloing who, in 1898, having obtained a fluid homogeneous culture of the bacillus of Koch, produced agglutination by serum procured from tuberculous patients or animals, and thus introduced the serum diagnosis of tuberculosis. Professor Arloing and myself then perfected the method, determined the best manner of cultivating the homogeneous cultures, applied the sero-diagnostic method to hundreds of patients, and made observations on the agglutinating power of blood in them and in animals which had been rendered tuberculous. I have investigated from a diagnostic point of view the nature of morbid serous fluids by means of the agglutinating power of those effusions, and have also examined pleuritic effusions with a view of obtaining aid in relation to prognosis.

The Lyonese method is now employed almost everywhere; opinions on this question are very numerous; and many authorities can be cited who have confirmed our conclusions. If some observers have contested the importance and value of serum diagnosis this arises from their not having avoided the sources of error.[2]

II.—*Proofs of the Value of the Serum Diagnosis.*

The best proofs are the good practical results which have been obtained by means of serum diagnosis by a great number of observers. But there are two kinds of proofs which are specially conclusive.

1. *Statistical data obtained from bovine animals.*—In cows statistics can be collected in which the serum reaction can be confirmed by necropsy. Under these conditions Professor Arloing has proved that the serum diagnostic test is always negative when the cow is not tuberculous and positive in 90 per cent. when tuberculous lesions are present.

2. *Statistical data in regard to tuberculous pleurisy in man.*—In pleurisy occurring in the human subject the tuberculous or simple nature of the malady can be determined by the clinical phenomena and by means of inoculation and cytology combined. In such conditions amongst 112 cases we have never had a positive reaction with the pleuritic fluid when the pleurisy was not tuberculous; on the contrary, we had 76 per cent. of positive reactions when the pleurisy was tuberculous. If the results of the sero-agglutination with the blood serum of human beings (tuberculous or not) are apparently less easy to interpret, this is due to the variations of the agglutinating power according to the form, the gravity, the course, or curability of the lesions, according to the age of the subject.

III.—*Comparison of Serum Diagnosis and Tuberculin Reactions.—Advantages of Serum Reactions.*

If one compares the results given by serum diagnosis and tuberculin reactions (subcutaneous injections or ophthalmo-reaction) one sees that these methods give similar results but all advantages rest with serum diagnosis. With these three methods the results are positive in most cases of active tuberculosis, the cases which give no reactions being often the gravest; for instance, in advanced consumption. With these three methods the results are positive in a fairly large number of cases in which neither the clinical examination nor even sometimes the necropsy can discover tuberculosis. The concordance of the results proves that there is latent tuberculosis with very slight lesions often compatible with good health and which can only be discovered by very delicate laboratory methods.

It is also extremely remarkable that injection of tuberculin and serum diagnosis give about the same percentage of positive reactions in patients who are not evidently tuberculous (40 per cent. with serum diagnosis and 46 per cent. with tuberculin, according to Beck). It is also curious to see that the ophthalmo-reaction is positive in the typhoid cases just as the serum reaction is. At any rate, the few objections which one can make to serum diagnosis (errors occurring in feverish cases and in typhoid fever, and the too great sensitiveness of the method which responds to the slightest tuberculous conditions, even those compatible with health) apply equally to the injection of tuberculin and to the ophthalmo-reaction, as has been explained above.

The great advantages of the serum diagnosis are the following:—

1. *Absolute harmlessness*, since the taking of a little blood cannot give rise to accidents or inconvenience, which cannot always be said of the tuberculin and ophthalmo-reactions.

2. *Facility of application*, since a few drops of blood suffice and it is not necessary to watch the patients during the course of several days, as in the other two methods.

3. *Importance of the variations of the agglutinating power.*—Given the harmlessness and facility of application one can repeat the reaction as often as one likes, and the variations of the agglutinating power are of great importance not only for the diagnosis but also for the prognosis.

4. *Applications of local serum diagnosis*, which is impossible with any other method.

IV.—*Local Serum Diagnosis.*

The serum reaction is generally made with blood serum; in this case it gives only a general serum diagnosis, simply proving the general specific impregnation of the blood with a given infection, no matter where the lesions may be. But we have demonstrated recently the possibility and the good results of a local serum diagnosis. This is made with local effusion of the serous membranes, for instance, in pleurisy. We have proved that when a serous membrane is infected by tuberculosis a local reaction is produced and agglutinins are formed locally, independently of what happens in the blood. The positive serum reaction with the pleural fluid furnishes the proof of the local tuberculosis. Our numerous works on the subject (more than 200 cases of effusions, of which 115 were tuberculous pleurisies) have been confirmed by Mongour and Buard, Widal and Ravaut, Dieulafoy, Landouzy, Sabareanu and Salomon, Hawthorn in France; Bendix in Germany; Kazarinow in Russia; Marini, Marchetti, and Stefanelli in Italy, and other authors whose statistics are absolutely in accord with ours. The most conclusive results are given by pleuritic effusions. The fluid from tuberculous pleurisies produced agglutination (76 per cent. of the cases in adults out of 115 cases). Negative cases, although tuberculous, occurred almost entirely in the graver forms. The non-tuberculous fluids are not agglutinated even in a strength of 1 in 5 (with the exception of two or three doubtful cases). The agglutinating power of tuberculous fluids is ordinarily less powerful than that of the blood serum; but it may be sometimes more powerful, or can exist only in the pleuritic fluid and not in the blood. It would therefore seem that the pleural membrane can produce *in loco* an agglutinative substance.

In practice: 1. A positive serum reaction is a sign of great value in favour of the tuberculous nature of pleurisies. A careful comparison of the serum diagnosis with the cytology and the results of inoculation of fluid in the guinea-pig prove the absolute accordance of the three

[2] The causes of error are discussed in detail in the paper published in the Proceedings of the Congress of Washington.

Three Lectures

ON THE

PATHOLOGY AND TREATMENT OF DIABETES MELLITUS, VIEWED BY THE LIGHT OF PRESENT-DAY KNOWLEDGE.

Delivered before the Royal College of Physicians of London

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL; HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL.

LECTURE III.[1]

Delivered on Nov. 24th.

MR. PRESIDENT, COLLEAGUES, AND GENTLEMEN,—I will now give attention to the sugar that may fail to be assimilated at the seat of absorption. There are grounds for considering that, in the absence of any large ingestion of carbohydrate food, it becomes mainly disposed of at the seat of absorption. What, however, escapes being here dealt with, passes to the liver, and becomes checked from further progress by being taken into the cells and converted into glycogen. Thus the liver constitutes a second line of defence against the flow of absorbed sugar into the systemic circulation, obviating the production of more or less glycosuria that would otherwise ensue if the sugar flowed on instead of being stopped.

There is nothing in the

STOPPAGE OF SUGAR AND ITS CONVERSION INTO GLYCOGEN BY THE LIVER

cells but what is comparable to the effect that is capable of being produced by the agency of the living cells of yeast. By intracellular enzyme agency, condensation or synthesis of the sugar molecules with the elimination of water is evoked in like manner as is known elsewhere to occur, and the product constitutes a store ready to be drawn upon as need may arise.

It does not fall within the scope of the matter in hand to enter into the question of the transformation of carbohydrate into fat, but it may be stated that doubtless the liver performs a steatogenic office. It now stands as an established point that carbohydrate may constitute a source of fat, and the *foie gras* derived from the goose may be taken as affording an illustration of the liver being capable of functioning in this direction. The point to claim consideration is to see how the storage of carbohydrate under the form of glycogen in the liver can be transported to the seat of utilisation in the tissues without passing as free sugar, and thereby being placed in a position to flow off with the urine.. We learn from Bernard's puncture of the fourth ventricle, that if glycogen does actually escape from the liver in the form of sugar, the fact is revealed through the production of glycosuria, varying in intensity according to the amount present in the organ.

The glycogen of the liver constitutes simply a storage of carbohydrate derived from the food, and responds in amount to that of the sugar that may happen to be reaching the organ through the portal vein. There is nothing unintelligible connected with it. Its accumulation runs strictly in line with that occurring in unicellular organisms, of which yeast may be adduced as an illustration. It is open to common observation to find in living nature that redundant carbohydrate, wherever existing, is put for storage into a form like that of glycogen, starch, cellulose, &c., in which form it steadily remains till a demand for it arises, when enzyme action is brought into play, and it is broken down into suitably adapted molecules for appropriation to the purpose needed.

Glycogen is known to be a body of wide distribution in the various textures throughout the animal organism. Viewed in the manner represented, its origin is readily to be accounted for. Let it be supposed that carbohydrate is taken on by a biogenic molecular complex. If employed in the production of energy, it will be consumed and disappear. If not, and the supply of carbohydrate is kept up, it will be cleaved off and stored up under the form of glycogen.

The operation is analogous to what occurs in the case of fat.

FAT SIMILARLY ENTERING THE MOLECULAR COMPLEX,

if utilised will disappear, whilst if not utilised, may be thrown off and stored, accounting for the fat granules and globules discoverable in cells on microscopic examination. The term fatty degeneration is ordinarily applied to this condition, and it is viewed as pathological, but it is in truth representative of a widely occurring physiological operation. It is true, it may occur under circumstances where cell action has been interfered with by a damaged cell state. Here, certainly, it may be regarded as falling within the domain of pathology. Muscular growth in response to increased muscular work is truly a physiological phenomenon, but when the work which gives rise to the growth is of an abnormal nature, as, for instance, in the case of the heart under the influence of valvular disease or arterial sclerosis, the condition falls under the name of hypertrophy, and is regarded as pathological, although the line of action is the same. Thus, a line of action which may be claimed as pathological may be based upon a physiological operative procedure.

The gist of what I am endeavouring to urge is that it is within the protoplasmic molecular complex that the play of changes takes place which gives rise to the phenomena of life; that carbohydrate, fat, nitrogen-containing matter, and, in addition, oxygen enter this complex; that the interactions occurring are attended with energy production through the instrumentality of oxidation as a final result, and that when it happens that the oxidisable supply is taken on in excess of consumption by oxidation, it is cleaved off as storage material under the form of glycogen in the one case, and of fat in the other, and thus circumstanced, it is available for subsequent utilisation when demand for it may exist. What is observed to occur in connexion with the leucocytes of the blood, and with muscular fibres, stands in illustration of the two kinds of cleavage spoken of.

Glycogen, then, is to be regarded as simply a reserve of carbohydrate material, ready, as in the case of fat reserve, to be drawn upon and utilised when it becomes wanted. Its special accumulation in the liver is to be accounted for by the position in which the organ stands in relation to food-supply. The main purposes to which it becomes applied are bioplasmic growth and energy production. For the latter, the chief seat of utilisation is in the muscles, and here the storage amount present is found to be in a great measure dependent on the rate of usage. With limb muscles deprived of activity by nerve section or tendon division, observation has shown that a larger accumulation is met with than in the muscles of the other limb left intact. Conversely, observation has likewise shown that under exercise, as, for instance, when a muscle is tetanised, a decrease of glycogen takes place.

Külz showed by his experiments on previously well-fed dogs, that under very forced exercise, glycogen might be made almost completely to disappear from the muscles and the liver in about six to seven hours. As far as the muscles are concerned, the glycogen is lying close at hand and has simply to be taken by the bioplasmic material that uses it up. I consider it must be assumed that, as in the case of starch in the vegetable kingdom, the glycogen molecule requires to be broken down into sugar molecules before passing into the molecular complex in which consumption takes place, and it may be reasonably inferred that, in accord with what is commonly noticeable, there is concerted enzyme action set into play to bring about what is required.

With regard to the glycogen in the liver, which, as seen, equally disappears, this is seated at a distance from where utilisation occurs, and the point now to be considered is how it becomes transported from one spot to the other and meanwhile escapes being placed in a position to show itself in the urine. We know when it happens, as after Bernard's puncture of the fourth ventricle, that the glycogen passes into the blood in the form of free sugar, the fact is revealed through the medium of the urine, but we have no disclosure recorded of any glycosuric effect having been produced by forced exercise, notwithstanding the short period within which the liver has been found to have become emptied of its glycogen.

No. 4450.

THE MILK-SUPPLY FOR INFANTS:[1] RECENT ASPECTS AND POSSIBILITIES.

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL; SENIOR PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN, CLAPHAM-ROAD, S.W.

Human Infants as "Physiological Tests" for Sound Milk.

GOOD milk for infants is a national concern since physical deterioration of the race and depopulation by infant mortality and by tuberculosis are mainly milk questions. The general milk-supply, which has been a frequent channel for epidemic infections, has been the only one to receive legislative recognition and help. It gets the benefit of a vast experiment in which the test subjects are not animals but human infants and has enjoyed it long before the general adoption of this "physiological testing" for the proving of drugs and of poisons. There are no more sensitive reagents for the quality of milk than delicate infants; they are our expert milk tasters. From their verdict and too often from their painful and slow death (or, in summer, from their rapid decimation) we learn that our average milk as sold to the masses is not all that milk should be. For in our towns it is from the common supply that the plebeian infant as soon as weaned gets his pittance, losing at one stroke, through our neglect, that footing of equality with the well-to-do infant which nature had established for them in the shape of maternal milk and of its dairy substitutes.

Salus Infantum Suprema Lex.

The right of the infant to a sound milk-supply is the first of our liberties and its mother should show proof that it is being properly fed, not starved or poisoned. By law British subjects are not permitted to starve; and to guard them from disease everything is jealously watched—in the street, in the farm, and in the house. The only unprotected, and left to perish in their thousands, are the infants. "Infant starvation" is an ugly but true fact. Its causes are the hitherto inadequate teaching of the practical duties of woman; and, secondly, the exclusion of infants and children from that State protection which is extended to adult citizenship. There lies the great cruelty. But whilst we wait for State action a field is open for the benevolent in the practical prevention of cruelty to infants and children, not so much by prosecution as by help of example and of education.

It is appalling that hitherto no provision has been made for a "guaranteed" milk-supply for the infants of the poor. What may be retailed for their use nobody cares and nobody knows. Little wonder that the mortality from infantile diarrhœa should remain to this hour undiminished in spite of the conquests of hygiene in every other direction; for it is but too likely that summer diarrhœa really spells *summer milk poison.* We know, the dairyman may know, but the unfortunate infant's mother does not know. She is not even offered that warning notice of an unsuspected danger which the alternative offer of a "special" if not of a "guaranteed" supply for the infant might have given her.

The Guiding Principles in the Milk-supply for Bottle-fed Infants. Living Milk and Dead Milk.

A cursory review of this matter will suffice.

I. There is only one perfect milk for the infant—*the living milk* straight from the breast. This is confirmed by the clinical value of such makeshifts as asses' milk and goats' milk drawn at the infant's residence for immediate use. Among mammalia there is only one instance, our own, of any storage of dead milk for the young.

II. One of the perfections of mother's milk is that it is *highly specialised* for the infant. For it there is no complete substitute, and a satisfactory approximation is often difficult to find.

III. *Singleness of supply* is another of nature's principles. "To each infant its own cow," provided the best cow for it can be found. But in practice well-known objections are apt to arise.

IV. *Sustained quality* of the single supply is the most important but the least probable attainment. The quality of mother's milk will often vary, but its fluctuations are human. Those due to bovine distempers are more serious to bear and slower for infants to get over. It may be best to seek safety in numbers, and after all to administer herd milk—on the plan of inuring the infant to constant variety—for in milk feeding habit plays its part as in the rest of physiology.

V. Again, in its composition nursery milk should be the nearest approach to the maternal. This involves an artificial rearrangement of the constituents of dairy milk, and this is the great principle of *percentage milk,* which Professor T. Morgan Rotch of Boston has elaborated and applied, and to which further reference will be made.

VI. *The sine quâ non is absolute freedom from the agents of disease,* whether as in scurvy-rickets they be special to the milk or, as in tuberculosis and all other infections, imported into it. Absolute safety from infection must be insured in infants' milk at any cost, and by some method which cannot possibly ever fail in the working. An absolutely sterile milk is the only adequate safeguard. But so long as we cannot avoid using dead milk we must be quite sure that it has not lost those qualities of living milk which are essential.

The Defects and Risks of the Common Milk-supply.

We cannot but marvel at the insecure equilibrium of our safety among many modern dangers too giddy for thought. And this applies also to our milk-supply. Day after day nothing happens (at any rate perceptible at the surface) until something does happen, and it is a catastrophe in the shape of some epidemic. The best of dairy systems for the million must accidentally break down now and again, and it seems to have been hitherto impossible to guarantee any milk in the slums. Nevertheless, great improvements have taken place within the last few decennia under the persistent pressure of professional opinion and of the medical press and through the untiring efforts of our public health officers. Thanks to legislation, and also, it is only fair to add, to the willingness and coöperation of the rank and file of the milk trade, the average quality of the ordinary milk as a food, particularly in respect of the percentage of its normal constituents, has improved considerably and we have heard much less of milk epidemics. But it is our business to criticise, and there is still much to be done.

From the special point of view of infants the inherent evils or imperfections are the following: (1) the evil of promiscuousness of supply, (2) the evil of seasonal and alimentary fluctuations, and (3) the evil of health fluctuations in the cow. To these must be added: (4) the prevalent but avoidable evil of chemical adulteration with milk preservatives. Accidental risks are also ever present—namely: (5) the risk of pollution,[2] (6) the risk of infective contamination, and (7) the risk of fermentation.

Special attention has been called to the magnitude of the evil from *adulteration with preservatives* by the report of the Departmental Committee of Inquiry into the Use of Preservatives in Food, London, 1901. This evil had passed unsuspected, though comparatively little milk had escaped drugging, leaving often no practical alternative for the local consumer. Infants who are exclusive milk feeders are with a few invalids the only ones to tell the tale, as a mixed diet confuses the issue. By them any adulterant is ingested in a much higher proportion to the total food-supply and up to a poisonous dose. This is shown by a growing distaste, dyspepsia, and finally absolute intolerance for the milk, which at last is immediately rejected. After unsuccessful trials of further dilutions milk feeding from the common supply comes to an end. Our infants are thus made to serve as our physiological poison tests; but whilst they turn from the cup we continue to use it. Their health or their life will have been sacrificed in vain if the conclusion is not enforced that milk preservation by chemicals must cease.

As regards contamination, in addition to the original pollution, the "open system" of retailing in the slums is also a remediable danger. All milk used for infants should be sealed. But in view of practical impossibilities the great majority of infants must depend upon herd-milk. The risk is then multiplied by the number of the herd, although it is true that the individual faulty milk, if there be any, is proportionately diluted.

The sealed supply of our best kind of fresh milk for infants is good and, with certain reservations, reliable. It is the glycogen molecules must be broken down into molecules of sugar. Now comes the important point bearing upon what next transpires. The *condition* is unassociated with hyperglycæmia, but hyperglycæmia should be present if the sugar molecules passed as such into the blood. It seems to me that we are driven to the conclusion that the *sugar* molecules must enter into combination with a constituent of the blood and then become set free again by the influence brought to bear when the kidney is reached. If a transport of sugar in one way or another occurs, as the evidence before us denotes it does, and it is not effected by passage in a free state, the only inference to be drawn is that the sugar is thrown out of sight by entering into a combined state.

---

[1] From notes of a demonstration held at the Medical Graduates' College and Polyclinic on Oct. 20th, 1908.

[2] Cf. THE LANCET, editorial article, The Pollution of Milk, Oct. 24th, 1908, p. 1226.

Physiologists accept this

EXPLANATION OF THE PHENOMENON OF TRANSPORT

connected with phloridzin glycosuria. If admitted here, why should it not be equally admitted as applicable to what happens in connexion with the ordinary occurrences of life? Forced exercise leads to a rapid emptying of the liver of its glycogen, without producing any show of the passage of sugar through the circulation in a free state. If the sugar goes into combination in the one case, why should it not do so in the other? The circumstances stand in reality upon an analogous *footing*. The abstraction of carbohydrate from the blood to compensate for its consumption in the muscles during forced exercise, will create a demand for its replenishment, and thence lead *to the store of glycogen* in the liver being drawn upon. In the case of phloridzin glycosuria, the outflow of sugar that occurs in the kidney will, similarly to forced exercise, draw off carbohydrate and give *rise* to a demand for reinstatement *from* the glycogen store. The line of procedure is the same in the two cases, but the initial condition that leads to the demand for the replenishment of carbohydrate in the blood is different.

Support is given to the view that has been set forth by the modified

CONDITIONS BELONGING TO PANCREATIC GLYCOSURIA.

Here hyperglycæmia precedes the glycosuria. The disappearance of glycogen occurs just as in phloridzin glycosuria, but the source of disappearance is conversion into sugar at the seat of storage. The kidney simply eliminates the sugar that is conveyed *to it in the* blood, and if the elimination is prevented by extirpation of the kidneys, the sugar goes on increasing, with the result of exceedingly high percentages having been noticed. The abnormality *proceeds* from a local transformation of glycogen into sugar, which recognisably passes into the blood in a free state, and subsequently flows off with the urine.

The instance that has been cited in reality shows what occurs when *sugar from* vanishing glycogen reaches the blood in a free state. In phloridzin glycosuria, there is equally a disappearance of glycogen, but nothing is seen, as far as the blood is *concerned, of the sugar derivable* from it. Proof is given that the sugar has not undergone destruction by the fact of its coming into view when the kidney is reached. It is simply for the time being concealed by entering, as may be legitimately assumed it does, into combination with a *constituent of the blood.* If, in the presence of these circumstances, things can run on in this way, is it not permissible to assume that sugar may be transported in a locked-up state from the intestinal *seat of food* absorption, and from that of glycogen storage, to where it is required for service? By admitting this, all difficulties at once disappear.

I have previously referred to Professor Macleod's article in Leonard Hill's "Recent Advances in Physiology and Bio-Chemistry" and criticised *the* grounds upon which he has sought to maintain the validity of the glycogenic doctrine. Although, in dealing with this point, he contends that there is a functional transit of sugar through the circulation in a free state, he falls in with the view of transit in a combined state, declaring *in the first* place (p. 319) "there is reason to believe that a loose chemical compound—of a colloidal nature—exists between serum globulin and dextrose"; next remarking (p. 363), that the mother *substance* of the sugar eliminated in phloridzin glycosuria is undoubtedly the serum proteid; and then saying (p. 364) that the proteid which has been thus deprived of its sugar "becomes re-combined with more of it during its circulation through the rest of the body." This, it will be seen, precisely represents what is claimed as constituting the physiological mode of transit.

There are further facts connected with phloridzin glycosuria that give support to the view that has been expressed. If repeated administrations of phloridzin are employed in a well-fed animal, continued elimination of sugar occurs without any material alteration of the associated nitrogen elimination. The carbohydrate of the food, in the first part of its onward march after absorption, follows the normal course, but *afterwards, through the agency of what occurs* in the kidney, becomes diverted into a wrong direction and flows off with the urine as sugar. This is what happens whilst there is

FOOD-SUPPLY OR A GLYCOGEN RESERVE TO BE DRAWN UPON,

and the circumstances are compatible with the carbohydrate being linked on as a side-chain to a blood-contained molecular complex.

With the absence of food, and when the glycogen has been swept away from its seats of storage, the position of things with regard *to the relative elimination of* sugar and nitrogen becomes altered. The sugar falls until it arrives at a fixed relationship to the nitrogen, and when this point is reached, it is assumable that both sugar and nitrogen are being derived from the breaking down of the molecular nuclear centre that was constructed at the time of the building up of the protein molecule. Evidently, in the one case, the carbohydrate is liberated without the destruction of the molecule, and in the other, the liberation is an accompaniment of *molecular disintegration.*

I have just spoken of the elimination of sugar in phloridzin glycosuria being connected with food supply. The carbohydrate in the food runs off as *sugar in the urine*, and it does this without showing itself as sugar in the blood. The only deduction that can be drawn from this occurrence is that it passes in a state of combination, and, in view of the intensity of the glycosuria that is sometimes observed, it is evident that the capacity for transit in this state must be very great. In pancreatic diabetes, the *eliminated sugar* is similarly connected with food supply, but the carbohydrate of the food reaches the circulation, and passes through it to the kidney in the form of free sugar. Thus, in both these conditions, the food carbohydrate passes through the system and *makes* its appearance in the urine as sugar. In connexion with the one, it passes through in a concealed (combined) state, as I contend happens in its conveyance in the healthy person to the *tissues for* utilisation. In connexion with the *other, it passes through* in a free or uncombined (unassimilated) state, just as it does in ordinary diabetes. Herein, then, it may be considered that we have

THE TWO MODES OF TRANSIT, THAT IN HEALTH AND THAT IN DIABETES, REPRESENTED.

I must not allow the remarks made by Professor Halliburton, in his advocacy of the glycogenic doctrine, contained in the article that has been already referred to on "Diabetes Mellitus from the Physiological Standpoint" inserted in the July number of the *Practitioner*, 1907, to pass without comment. At the present stage a fitting place is offered for referring to them, and I will proceed to avail myself of it. The question of the sugar formation by the liver is being spoken of, and the following line of reasoning *is set forth.* "*At the present* day, the prevalent opinion among physiologists is of the nature of a compromise between the two extreme views. The liver is, no doubt, able to convert part of its glycogen into fat, but most of its glycogen is regarded as leaving the liver as sugar (dextrose). In coming to the latter conclusion, physiologists are influenced by what they learn from *surviving organs* generally. An excised organ is undoubtedly on the road to death, but *while it still* retains vitality, the phenomena it exhibits are similar in kind to, though they may be different in degree from, those which it exhibits during life. It is impossible to suppose that, at a given moment, arbitrarily called death, an organ can turn round and do what it never did before. Even in the case of blood coagulation, which appears to be a direct instance *to* the contrary, there is no doubt, from recent research, that *the* blood is always *tending* to clot even during life, and is prevented from doing so by the production of anti-substances (anti*thrombin* produced in the liver), which neutralise the activity of the thrombin or fibrin ferment."

It is a matter of

SURPRISE TO ME TO FIND THAT PROFESSOR HALLIBURTON HAS WRITTEN IN THIS WAY

in the face of what is contained in my work on "Carbohydrate Metabolism and Diabetes," a presentation copy of were cold and there was increasing pallor until the face became ashy grey. The skin was dry; there was no cold, clammy perspiration, as in an ordinary fainting attack. Consciousness was never lost, but there was present the sense of impending death. The pupils dilated in the worst attack and in all the eyelids were kept separated; the eyes rolled slightly and blinking was almost arrested for the time. The pulse became exceedingly infrequent, of low tension, and at times almost imperceptible to the touch; the breathing was shallow, hurried, and costal in type. The patient did not willingly speak but answered in monosyllables if spoken to. She was so "bowled over" that she had no energy even to call attention to her condition. Until the nurse was told to be on the watch for the attacks she would have one and recover without its being noticed, and she would merely remark afterwards that she had felt "dished" again. The attacks ended with a deep-drawn breath or sigh and if anyone was sitting by her she would remark, "That's all over now, I am better again." The attacks were very alarming. They in no way resembled an ordinary fainting attack. Their duration was about ten minutes.

Frequency of attacks.—She definitely remembers the first attack she had, which was while she was in East Africa. Subsequently she had them at intervals of weeks and later of days after any severe exertion. When she came under observation she was having one about every other day, except on one occasion when she had two in one day.

Mental state.—Sir William Gowers notes in his lecture "that with the vagal symptoms there is often a slight mental change and disturbance of the vaso-motor centre causing constriction of the vessels and coldness especially of the extremities." In addition to the extreme sensation of fatigue felt at the commencement of the attacks the patient was in a very unstable mental state generally. At times she would be very excited, her condition resembling the first stage of alcoholic intoxication. She would be intensely funny, make the most ludicrous, sometimes clever and sometimes senseless remarks; she would be very restless, "longing to get out of bed, and fly away." She followed up suggestions rapidly and talked and laughed incessantly. These attacks if uncontrolled lasted hours, but she could calm herself by a great effort of the will in from half to three-quarters of an hour. As she recovered, these excitable states lessened in frequency and severity, simply showing themselves in high spirits. The excitable state generally followed a condition of extreme depression with or without a definite "vagal attack." During these depressed periods she would be very irritable and melancholic. Both the excitable and the depressed states began and ended suddenly. She was wont to liken herself to Mother Hubbard's dog, whose mistress—

"Went to the joiner's to buy him a coffin,
And when she came back the dog was a 'laffin'."

A vaso-motor change was also noticed in connexion with these states. During the former she had a good colour, was even flushed, and looked very fit. During the latter she was pale, thin, and drawn, and often grey looking.

Treatment.—The general treatment was a modified Weir Mitchell. She was kept absolutely in bed and at rest and had abundant but not excessive diet, four pints of milk in 24 hours in addition to three substantial meals. The attacks themselves were shortened by the use of brandy or sal-volatile or both, and on several occasions hypodermic injections of strychnine had to be given. Easton's syrup was beneficial but she developed spasm of the abdominal muscles even with small doses of strychnine, so a mixture resembling Easton's syrup but with digitalis substituted for strychnine was ordered. The latter drug was more useful than anything else. It was not tried at first on account of the slow pulse. After she had been taking this mixture for some time she developed strangury and frequency of micturition. The spasm was so severe as to squeeze out some drops of blood. As there was nothing abnormal in the urine, I thought it probably due to some ingredient in the mixture, and added tincture of belladonna. She continued to take this without further trouble. The rapidity with which she developed poisonous symptoms with quite small doses of drugs which otherwise were acting so beneficially made the case somewhat difficult to treat.

Present state.—For a month there was little improvement in her condition, but from that time there has been steady progress. The attacks became less frequent and she was apparently well as long as she was resting in bed. The exertion of getting up caused a recurrence of the attacks at first, but a few days' rest in bed enabled her to repeat the experiment without ill effects. The same results occurred each time she made a fresh effort of any kind. She was under close observation for 14 weeks and then went into the country for two months. Although the attacks ceased she still had definite bouts of extreme fatigue and a feeling of old age. At these times, which occurred distinctly at the end of each fortnight, she would be very sallow, lacking energy, and drowsy, often sleeping day and night. They usually ended in a burst of excitement. She also had occasionally a feeling in the cardiac region which she described as "if the blood wanted to get through the heart but could not." At these times she was breathless. She is now able to undergo considerable muscular exertion, has bicycled, and apparently is perfectly well. She has gained in weight, has a good colour, and sleeps soundly. Her mental state is normal. She is still taking digitalis with carminatives, but without iron and quinine, as when she stops this she develops unpleasant sensations in the cardiac region and feels fatigued.

Subsequent note.—Nov. 23rd, 1908. The patient's condition has improved considerably. She had two slight "attacks" in January of this year, but none since. Her mental state is normal and she can lead an ordinary life. The day following any special exertion she gets breathless and the heart drops a beat at varying intervals. There is no regularity in the intermission of the beats, the intervals between the missed beat being never the same twice. In addition to the digitalis mixture I find trinitrin useful for this irregularity but she requires 1-20th of a grain to produce any effect.

Comments.—Although the attacks were so exceedingly serious and threatened to end the patient's life, yet there was apparently nothing in the local condition of the heart to point to a serious lesion. Between the attacks the patient suffered from no heart symptoms, no dyspnœa, œdema, palpitation, or flushing. Her condition, taken as a whole, seemed to indicate instability of the circulatory mechanism. Whether this was due to an affection of the vaso-motor centre in the brain (possibly dependent upon an attack of sunstroke while in East Africa), or to the effects of tropical heat or light on the blood-vessels of the surface of the body, or to some toxin circulating in the blood affecting the heart or vaso-motor system is uncertain. Dr. F. W. Hewitt in his lectures on General Surgical Anæsthesia[1] describes the clinical phenomena of circulatory surgical shock as slowing, feebleness, and irregularity of the pulse, coupled with pallor, coldness, and perspiration of the nose, forehead, and other parts, separation of the eyelids, a lessening in the depth of respiration, and in severe cases dilatation of the pupils. Apart from the perspiration this is an exact description of the condition of the patient during an attack. Later he says: "The clinical phenomena.. ... would seem to indicate that the surgical stimuli acting through sensory or sympathetic nerves primarily affect in most cases both the cardio-inhibitory and vaso-motor centres, with the result that a fall in blood pressure takes place ...... According to Crile, the condition is principally one of vaso-motor paralysis brought about by the nerve injury paralysing the main vaso-motor centres, the result of the paralysis being a fall of blood pressure and an accumulation of blood within the venous system and particularly within the vessels of the splanchnic area."

Whether in this case there was some affection of the vaso-motor centre alone which secondarily caused the bradycardia or whether the cardio-inhibitory centre was also affected is uncertain. The evidence seems to point to a primary affection of the brain centres as there was nothing to show the attacks could have had a reflex origin from nerve irritation. If the attacks were not of vaso-motor origin at all another possible explanation seems to be that after any special exertion the heart, as it were, went on strike and a functional disturbance resulted showing itself in slow and insufficient muscular action. But were the cause of the attacks primary muscular insufficiency with normal blood pressure dilation would probably have occurred. This evidently did not happen, as neither the symptoms nor the physical signs showed that condition.

It is of interest that the attacks should usually be traced when transmission through a cell membrane is wanted. This operation, followed by saponification, provides for the transmission, and then, should the conditions be such as to lead to neutral fat coming into view, a re-synthetic action is brought into play. What has been stated stands in accord with the teachings of the present day, and it is seen that the line of procedure in the case of fat fits in with that appertaining to carbohydrate.

---

[1] THE LANCET, July 27th, 1907, p. 212.

These phenomena cannot for a moment be conceived to issue from the effect of mere chemical action working independently of the influence of living power. Everything tends to show that actual

INCORPORATION IN LIVING MATTER PRECEDES METABOLIC ACTIVITY.

Living matter is made up of more or less highly complex molecules, and, thence, saying that a body enters into the constitution of living matter is tantamount to saying that it enters into the composition of the complex molecules of which it is made up. This renders it justifiable to speak of living action as resulting from incorporation of food-stuff in the bioplasmic molecules and its subjection to the influences that are there existing. Intramolecular activity in this way stands at the foundation of living action.

Now, taking carbohydrate and fat, it has to be said of them that they both, in a suitably hydrolysed state, become linked on to the bioplasmic molecules. What subsequently occurs depends upon the circumstances at the time existing. If they are oxidised, they disappear in the form of carbon dioxide and water, giving rise to the liberation of a concordant amount of energy of one kind or another. If they are not consumed in this way, and the supply of nutrient material goes on, they become dissociated and laid by as storage stuff—the carbohydrate in the form of glycogen, and the fat in the form of glyceride or neutral fat.

I strongly demur to the terminology that is in common use among pathologists in connexion with this matter. It is a "terminological inexactitude" to speak of these operations as falling generically in the category of degenerations. They are virtually in themselves of a physiological nature, and, moreover, constitute representations of, it may be said, the largest and the widest spread class of action occurring in the living world. Look at the production of starch, cellulose, &c., and of fats in the vegetable kingdom, and of glycogen and fats in the animal kingdom, as the issue of indisputable physiological procedures. It is through bioplasmic agency that the phenomenon is brought about. Either carbohydrate or fat, entering the bioplasmic complex and not being oxidised or consumed, will not remain fixed there, but be dissociated or thrown off in one form or another, according to the potential conditions existing. Carbohydrate may enter and be thrown off as carbohydrate, and fat as fat; or, it may be, that carbohydrate may be taken on and fat cleaved off, or fat enter and carbohydrate be cleaved off.

Illustrations demonstrative of these actions are readily obtainable from the vegetable kingdom. With respect to the production of fat from carbohydrate, I may cite a passage from Sachs, quoted in my "Physiology of the Carbohydrates" (p. 247): "Before maturity such [oily] seeds contain no fat, but only starch and sugar. Such unripe seeds (e.g. of *Pœonia*) may be detached from the mother plant, and allowed to lie in moist air with the result that the starch disappears and is replaced by fatty oil." With respect to the production of carbohydrate from fat, the growth of the oily seed suffices to afford a demonstration. From the oily seed placed in contact with water, a young plant springs, just as happens with its starchy congener, the fat obviously constituting the source of the cellulose that comes into existence. Concordantly, there cannot be any doubt about fat emanating from carbohydrate as a metabolic procedure in the animal kingdom, but concerning the production of carbohydrate from fat, I do not consider that any point of evidence is yet before us that can be definitely said to settle the question.

I submit that, in the dissociation process of which I have been speaking,

CARBOHYDRATE AND FAT STAND UPON IDENTICALLY THE SAME GROUND.

The matter is very simple and intelligible. Both form an integral part of bioplasm. If in excess, arising from supply, or from production within as in the case of fat from carbohydrate, of the consumption taking place, they become dissociated as storage material.

The dissociation seems to play a balancing rôle. What is not used is for the time thrown off. This is well seen in the case of yeast cell growth in association with a plentiful supply of sugar. The sugar is taken, and that which is in excess of application is thrown off as glycogen. The adipose tissue cells, although replete with fat, go on taking it if it is presented to them. Because it is not actually wanted does not stop the process of taking on. When the supply fails and it is wanted elsewhere, then a reverse action occurs, and it is taken back and transported to where it is needed for consumption, just in the same way as occurs with carbohydrate. What I submit is that, as a general principle of action, the taking on does not necessarily cease when what is taken on is not consumed.

Here lies the

FOUNDATION OF THE SO-CALLED DEGENERATIONS.

They simply represent thrown off material which has been incorporated into bioplasm, or produced within it, in excess of consumption. The liver is full of activity in this way. Standing in the position it does in relation to food, it is brought into contact with supply material to a greater extent than happens elsewhere, and do we not accordingly find that in this organ, more than anywhere else, accumulation of fat and carbohydrate is observed to take place?

Thus far I have been dealing with the supply as standing at the foundation of the condition that may happen to be met with. Taking the other side of the question, a check to consumption may be the determining cause of accumulation. Whilst consumption is balanced to supply, no opportunity exists for the occurrence of dissociation. Should consumption, however, fall short, surplus material will come into existence and show itself as a dissociated product. The two main sources of dissociation of this kind are deficient supply of oxygen and inactivity. From whatever cause arising, these conditions are known to give rise to accumulations of both fat and glycogen. Damage of cell bioplasm through toxic agency, as for instance from diphtheria, &c., will, by the instrumentality of its check to activity, give rise to the condition that is being considered.

Under the view set forth, the whole matter is placed upon a rational basis and made clear and intelligible. Degradation of protein into fat, after the manner that was formerly entertained, does not enter into the question. The operation, in fact, consists of a throwing off, precisely as is done upon a most extensive scale, as a normal metabolic procedure, in both kingdoms of living nature. The act of throwing off, as has been seen, is subordinated to the influence of the collateral conditions existing. When these conditions are normal, the process is a physiological one, and there is nothing of a degenerative nature about it. It is only when the throwing off is occasioned by a pathological state that the term "degeneration" can be justifiably applied to it. The distinction that applies to the terms "growth" and "hypertrophy" is strictly applicable in connexion with the point under consideration. To use the term "degeneration" in the manner that is too often done, is absolutely unscientific and misleading.

We learn, both experimentally and clinically, that

THE PANCREAS IS MIXED UP WITH CARBOHYDRATE METABOLISM,

and let me now pass to the consideration of this subject, and see the kind of reading that may permissibly be put upon the facts that have been disclosed in connexion with it.

Our predecessors of many years back recognised that disease of the pancreas was from time to time met with in the post-mortem examination of persons who had died from diabetes. The recognition in modern times that diabetes follows experimental extirpation of the pancreas, stands in conformity with this, and, as it is found experimentally that for the production of the effect the extirpation must be complete, so from modern clinical experience it is learnt that partial disease of the organ may exist without being attended with diabetes, whilst with extensive disease of it, diabetes may be expected to be found as a concomitant.

Something, then, derived from the pancreas is apparently concerned in contributing to the normal metabolism of carbohydrate, inasmuch as in the absence of this something, carbohydrate shows itself as sugar in the system in a manner that does not occur when the proper passage to utilisation is carried out. Now, in the proper passage of food molecules to utilisation, a preliminary linking on to the various bioplasmic molecules of the body is, at the present time, pretty

A CASE OF

LATERAL SINUS THROMBOSIS WITH PYÆMIC PULMONARY AND PERICARDIAL COMPLICATIONS, ETC.;

OPERATION; RECOVERY.

BY JOHN MACKIE, L.R.C.P. EDIN.,
AND
H. BELL TAWSE, M.B. ABERD., F.R.C.S. ENG.

NOTWITHSTANDING the almost weekly reports of recovery after lateral sinus thrombosis we consider the following case sufficiently uncommon to be worthy of addition to the list.

The patient, a well nourished boy, aged 15 years, had constant discharge from the left ear for eight years, with attacks of earache when the discharge lessened. The pain abated after poulticing, and free discharge of foul pus relieved the other symptoms. For the past two or three years these attacks were accompanied by mastoid pain, which in recent months was more acute. Lately more severe symptoms had been superadded during an attack and giddiness, distressing tinnitus, sickness and vomiting, with acute general headache, restlessness, and delirium developed, before a copious discharge of pus—a discharge so profuse that seemingly it could not have come from the tympanum alone—relieved his condition. On Sept. 26th, 1906, a more severe attack than usual led his parents to call in Dr. Harvey Francis of Arnold, who recognising the serious nature of the case telephoned for Mr. Mackie. The boy was found to be exceedingly ill with all the symptoms of serious extension of his ear trouble. The left meatus was full of foul granulations, and appliances for the removal of these being at hand it was decided to clear these out and to await developments for a few hours. At this time there were pain and tenderness over the mastoid and the temperature was 104° F., but there was no evidence of a thickened jugular vein and the cervical glands were not enlarged. On the next day there was no improvement. If anything the patient seemed worse. His temperature had ranged from 105° to 97°, accompanied by rigors and sweating, leading to a diagnosis of lateral sinus thrombosis. Immediate operation was decided upon. The mastoid process was exposed by the ordinary incision behind the ear, and on chiselling through the cortex the anatomy was found in rather a confused state. The mastoid antrum was continuous with the cavity of a seemingly chronic extradural abscess, the tegmen antri and tympani being replaced by soft, pulpy, foul-smelling granulation tissue. On removal of this the dura mater was exposed over a large area, and working backwards towards the sinus through dirty washleather-looking material the sinus was reached, the vein wall being unrecognisable as such. The thrombosis was not disintegrated and came away quite easily, free bleeding being established from both ends. No pus was found in the sinus. On commencing the operation the question of tying the vein was left an open one, and at this stage, taking into account the collapsed condition of the patient and the free bleeding from both ends of the sinus, it was decided to leave the vein alone. As the disease had practically performed the radical mastoid operation the wound was partially closed and provision was made for free drainage. For the next two days the patient was naturally in a critical condition. He had daily rigors, followed by rapid rise of temperature. On one occasion the temperature fell from 104° to 96·2° in a few hours. Nevertheless, the patient expressed himself as relieved, took nourishment freely and retained it, and had an average pulse of 80 beats to the minute. On the third day after operation (Sept. 30th) the temperature fell to subnormal and remained there a few hours and the patient seemed to be doing very well, but towards the evening of that day his breathing became laboured and on the next day left basal pneumonia and pericarditis were added to his troubles. Little could now be done but watch the case. The patient was full of pluck and, apparently unaware of his critical condition, was making a good fight. He remained in much the same condition till Oct. 6th—nine days after the operation and five days after pneumonia was recognised—when the temperature, after running up to 106·2°, in three hours dropped to 95°—a fall of 11·2°. There were almost daily rigors but the pulse remained fairly strong. The appetite was good and the patient frequently expressed himself as being "all right." After this, and contrary to all expectations, matters improved and on Oct. 9th the temperature had been normal for 48 hours. On the 10th it suddenly rose to 104·2°, a severe rigor was experienced, and the temperature fell to 99·4°, and soon after about half a pint of thick foul-smelling blood-stained greenish pus was expectorated, evidently from a pulmonary abscess. The patient's general condition remained fairly satisfactory, with occasional rises of temperature to 101° until the 13th, when he complained of sore throat and pain about the angle of the jaw on the left side and along the course of the internal jugular vein. A swelling soon appeared in the neighbourhood of the angle of the jaw and it gradually increased until the 19th, when the neck was laid open from the mastoid tip to the sterno-clavicular-articulation. The internal jugular vein, which was small and feebly pulsating, was tied at its junction with the subclavian. The ligature of the vein was temporarily followed by unilateral facial cyanosis which rather alarmed the anæsthetist. A large abscess was evacuated at the upper part of the neck, a drainage-tube was inserted, and a gauze drain was introduced down to the site of ligature. Stitches were put into the rest of the wound and were left untied until four days later. The wound healed by first intention, the abscess cavity gradually filled up and closed, the temperature remained normal, and the patient was discharged on Oct. 31st with a healthy granulating wound over the mastoid. This soon healed up and now he is in excellent health. The cervical scar became painful and markedly keloidal, but the application of x rays has materially reduced the thickening and dispelled the pain.

It seems very probable that in this case there was an extradural abscess of some standing, which had at intervals filled up and discharged through the meatus and that ultimately the sinus wall became involved and a thrombosis resulted. This, perhaps, is not an unusual occurrence, but to have recovery after such complications as pulmonary abscess and pericarditis is certainly very rare.

The case showed a few interesting points, such as the fall of 11·2° of temperature in three hours, the unilateral cyanosis after ligature of the jugular vein, and the remarkable physical and mental stamina of the patient, who never realised the seriousness of his condition. Thickening along the course of the internal jugular vein, reported in most text books as being present in sinus thrombosis, was absent in this case—in fact, neither of us has seen it in previous cases.

Nottingham.

A SIMPLE METHOD OF OBTAINING A PREPARATION OF LIVING ISOLATED LEUCOCYTES.

BY CONSTANT W. PONDER, M.A., B.C. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.

(From the Cambridge Pathological Laboratories.)

THE following method of preparing a field of living leucocytes, free from the other elements of the blood, was evolved during the course of a piece of research work, and it seemed to me that it might be useful to those working with leucocytes and could also be used to demonstrate to the student in a striking way the living entity of the white blood cell.

No unusual apparatus is necessary. A warm stage, made by a strip of copper, one end of which is heated, while the other, resting on the microscope, has a hole corresponding to that in the stage; a white porcelain staining dish for washing the slide; and a material which can be obtained anywhere, "plasticine," or modelling clay, which is used to prepare the blood-chamber hereinafter described, are all that is required. An incubator at blood temperature is a useful refinement. A bath of warm, normal, saline solution (0·75 per cent.) at blood temperature is to be prepared in the porcelain dish, and can be kept ready by resting it on the hotter end of the copper strip. A point can easily be found where its temperature will not vary more than a degree or two from 38° C. This simple arrangement is shown in the diagram (Fig. 1).

The mean of the figures yielded came out at 2·03 per 1000, the maximum being 2·47 and the minimum 1·57.

In four experiments of a similar nature with levulose, the mean figures stood at 2·07 per 1000 with the maximum at 2·56 and the minimum at 1·74.

One experiment was conducted with the injection of the raw extract of pancreas in association with dextrose. The injection proved immediately fatal, and the figures met with were 1·04 per 1000. These low figures are not surprising, seeing that the physical effect of the injection of the sugar solution would be to lead to a dilution of the blood, firstly from the fluid injected, and next from the hypertonicity given to the blood leading to fluid being drawn into it from the tissues.

Five experiments are recorded with the subcutaneous, instead of intravenous, injection of pancreatic extract and dextrose. The mean figures stood at 1·77 per 1000, the maximum being 2·09, and the minimum 1·52.

In one experiment of a like nature with the employment of levulose, the figures stood at 2·30 per 1000.

With reference to the precise signification of these experiments, all that is at the present moment needed to be done is to urge that they suffice to show that the pancreatic extract really exerts an action in relation to the passage of sugar into amylose carbohydrate. I will now enter upon the question of *modus operandi*.

The amboceptor in immunity phraseology seems to stand as the representative of the co-ferment concerned in enzyme action. It is now known that enzymes are dual bodies, and that the two parts are capable of being separated from each other. When separated, neither possesses any enzymic power. One is destructible by heat and seems to be the active agent, corresponding with the complement in immunity language. The other does not lose its virtue by subjection to boiling, and thus stands in the position of that which gives power to thyroid and suprarenal extracts. Taking the expressed juice of yeast, which contains zymase—the enzyme which converts sugar into alcohol and carbonic acid—a given quantity of the fresh juice has been found experimentally to have its enzymic power doubled by the addition of an equal quantity of boiled juice. This means that an extra quantity of the co-ferment, which possesses no inherent active power, gives increased power to the essentially active principle of a "complement" nature that is present in the juice.

The effect of the co-ferment is seen to be comparable to that of the pancreatic extract, and both, on account of having been exposed to a boiling temperature, must be devoid of energy-exerting power. It is obvious that the co-ferment must, in some way or other, contribute the assistance to the potential part of the enzyme which enables it to bring about the increased effect that has been spoken of. The possession of a linking-on power of an

AMBOCEPTOR

nature would suffice to supply what is wanted, and in functioning in this way, an explanation is afforded of its mode of action which satisfactorily fits in with the explanation given in connexion with operations of another, but probably allied, nature.

In the case of hæmolysins and bacteriolysins, it seems to have been experimentally reduced to demonstration that a something becomes developed within the blood which plays the passive part of connecting a lytic body (complement), present as an ordinary constituent of the blood, with that which undergoes dissolution. Without the aid of this connecting body (amboceptor), the red corpuscle and the bacterium fail to be attacked, notwithstanding they are surrounded by "complement." The amboceptor is reasonably assumed to possess a linkage capacity which leads to its joining up the complement with the red corpuscle or the bacterium, and thus placing it in a position to exert its lytic influence upon them, which, in the absence of the junction, it is powerless to do.

Through the instrumentality of the amboceptor, then, the complement is linked on to the bioplasm, and until this occurs no action takes place. The food molecule also requires, as I have before said, to be linked on to bioplasm before it can be turned to account. I think it is now pretty generally admitted that it is within, or as an integral part of bioplasm, that it is made use of, and that whilst outside bioplasm, it can no more be metabolised than a toxin molecule that has had its linking-on capacity abolished can produce a toxic effect.

Molecular configuration has been spoken of in connexion with the chemical union of bodies and it has been asserted that there must be a mutually adapted configuration to permit of junction taking place. Now, why may it not happen that amboceptor aid is required for linking the sugar molecule on to bioplasm? The facts before us bearing on the position held by the pancreas in relation to the matter under consideration suggest that it is. Acceding to the proposition that an amboceptor is needed for the linking-on of the sugar molecule to bioplasm, and that the pancreas is concerned in its supply, everything fits in and becomes placed on a clear and intelligible footing. If the aptitude does not exist for the monosaccharide molecule to be linked on to bioplasm, it becomes placed in the same position as a disaccharide molecule, which, whilst remaining as such, plays no part in connexion with living matter, and, if reaching the system, becomes thrown off with the urine in the same way as any other extraneous or unutilisable material.

The point reached is that the facts before us suggest that

THE PANCREAS SUPPLIES AMBOCEPTORS

which, by effecting the attachment of the sugar molecule to the bioplasmic molecule, place it in a position to be disposed of according to the existing environment. It may undergo oxidation and disappear with the liberation of energy. It may become transmuted into glycogen (amylose carbohydrate). For this, it must be conceived to pass in the first place into bioplasm, in the same manner as the hydrolyte is conceived to pass into union with the enzyme preparatory to being converted into another form. Or it may be transformed into fat by a process analogous to that of transmutation into glycogen—that is to say, as a result of a molecular rearrangement taking place within the bioplasmic complex. The liver cells, in a marked manner, afford illustrations of the capacity existing in bioplasm of producing glycogen and fat from sugar. The action is comparable to that of a ferment, in so far that a body enters in one form and is thrown off in another.

In the case of the intravenously injected sugar without the pancreatic extract, it has been seen that a small increase in the amount of amylose carbohydrate obtained upon that normally obtainable, occurred. This may be taken to be attributable, under the view adopted, to amboceptor derivation from the pancreas normally existing in the blood. The linking-on agency would be increased by the association of the pancreatic extract with the sugar solution, and here the amylose carbohydrate was found in a very distinct manner to be further augmented. The facts exist with which the reading given fits in as a rational deduction.

I look upon the leucocytes of the blood as one of the

AGENCIES CONCERNED IN THE PRIMARY METABOLISM OF CARBOHYDRATE MATTER.

They admittedly feed upon material that may chance to be present in the blood, and in this way extrinsic nutrient matter that may happen incidentally to reach the blood may be appropriated and built up into bioplasm, which, like that of the lymphocytes, may pass by autolysis into the blood proteins. We have here an agency that may be instrumental in putting available matter of any kind that may in any way get into the blood, into a condition of elaborated blood pabulum.

As yet I have only applied the line of argument adduced to action occurring in the blood. But the blood is not the medium designed for the food carbohydrate to be dealt with. The work of construction into bioplasm is performed before the blood is reached by the agency of the lymphocytes. Upon this subject I have already fully spoken. Leucocytes are little masses of growing bioplasm. Lymphocytes are, in this sense, the same, and the same train of occurrences in connexion with growth may be reasonably assumed to ensue. By analogy the line of working with respect to the point before us may be carried from the one to the other. If the amboceptor is in operation, as a means of linkage of the sugar molecule to the bioplasmic molecule in the leucocyte, it may be equally taken to be similarly in operation in the lymphocyte.

This brings the amboceptor factor into connexion with the broad question of the passage of carbohydrate into the assimilated state. That it does become an incorporated constituent of protein is regarded as an accepted fact. With this before us, let it be supposed that through faulty action the was heard, just at nightfall, by a peasant, who brought assistance. Two days later a radiogram made at the Zürich University Clinic confirmed the diagnosis of a rupture of the ligamentum patellæ. Professor Schlatter opened the knee-joint by a vertical incision over the patella and the ligament, removed the accumulated blood clots, and fixed the ligament, which was completely torn through, to the lower border of the patella by strong silk sutures. The leg was immobilised. There were some fever, pain, and an increasing swelling of the joint, symptoms which a puncture proved to be due to a turbid serous exudation, necessitating a second intervention of the surgeon a week after the first operation. After reopening the wound and removing a few stitches, incisions were made on both sides of the joint and the articulation was kept drained for a fortnight. The first incision healed by granulation, leaving a big scar adhering to the patella and the ligament. After several months of massage and exercise I was able to engage in most sports except climbing. Going down steep slopes is still, six years after the accident, very difficult for me. The leg can be bent to an angle of about 30 degrees.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL SECTION.

Exhibition of Cases, Specimens, and Models.

A MEETING of this section was held on Nov. 6th, Dr. J. DUNDAS GRANT, the President, being in the chair.

The PRESIDENT showed a case of Extrinsic Epithelioma of the Larynx in a woman, aged 28 years.—Sir FELIX SEMON remarked on the extreme rarity of cancer of the larynx in women, and stated that when it was present it was invariably of the extrinsic variety.—Dr. WILLIAM HILL objected to the word "extrinsic" and suggested that the nomenclature of the disease should be revised.—Dr. J. JOBSON HORNE and Dr. R. H. SCANES SPICER took part in the discussion.—The PRESIDENT replied.

The PRESIDENT also showed a case of Thyro-lingual Sinus in a boy.

Sir FELIX SEMON showed (1) a case of Epithelioma of the Left Vocal Cord; and (2) a case of Extensive Epithelioma of the Larynx.—The question of the advisability of operating in the second case was discussed by Dr. STCLAIR THOMSON, Mr. HERBERT TILLEY, and the PRESIDENT.

Mr. TILLEY demonstrated a case of Interarytenoid and Subglottic Infiltration of Fifteen Months' Duration causing Difficulty of Breathing, which necessitated tracheotomy, by means of Brüning's apparatus for direct examination.

Mr. CHARLES A. PARKER showed a case of Malignant Disease of the Right Maxillary Antrum involving the Outer Wall of the Nose and the Cheek in a male aged 68 years.

Dr. P. H. ABERCROMBIE showed a case of Perforation of the Soft Palate following on a severe attack of scarlet fever in childhood.—Sir FELIX SEMON, Dr. PATERSON, Dr. HILL, and Dr. R. E. SCHOLEFIELD discussed the case and agreed that while similar cases were almost invariably due to syphilis, yet scarlet fever, measles, and traumatism might all cause similar conditions.

Dr. STCLAIR THOMSON exhibited a case of Laryngeal Vertigo in Early Tabes.—Sir FELIX SEMON suggested that laryngeal crises would better describe the condition.—Dr. H. LAMBERT LACK, Dr. H. W. FITZGERALD POWELL, Mr. C. A. B. HORSFORD, Mr. PARKER, and the PRESIDENT also discussed the case.

Mr. J. GAY FRENCH showed a case of Extensive Fracture of the Walls of the Frontal Sinuses.

Mr. HAROLD S. BARWELL showed a case of Congenital Occlusion of the Right Posterior Naris.—Dr. J. B. BALL, Dr. P. WATSON WILLIAMS, Dr. SPICER, Dr. MCDOUGALL, Dr. PATERSON, Mr. E. CRESSWELL BABER, and Mr. H. CLAYTON FOX discussed the origin and the best means of operating in such cases.

Dr. HILL showed a case of Epithelioma Primarily in the Posterior Wall of the Pharynx now invading the Œsophagus and Larynx.

Dr. DAN MCKENZIE showed a case of Tuberculous Disease of the Larynx.

Mr. W. STUART-LOW exhibited (1) a case of Recurring Epistaxis, and (2) a Woman with Rhinoscleroma (microscopic slides were shown).

Dr. G. C. CATHCART showed a case of Deflected Septum causing Complete Occlusion of the Right Side of the Nose.

Dr. LAMBERT LACK showed a case of Lupus Erythematosus of the Face, with Patches in the Mucous Membrane of the Palate and the Inside of the Cheek.—Dr. BALL and Mr. T. J. P. HARTIGAN discussed the case.

Dr. L. H. PEGLER exhibited a case of Primary Tuberculous Granuloma of the Triangular Cartilage.

Dr. JOBSON HORNE showed a case of Intrinsic Laryngeal Growth in a Woman aged 64 years.

Mr. E. W. ROUGHTON showed a case of Malignant Disease of the Thyroid Gland.

Mr. ARTHUR H. EVANS showed the Right Half of a Larynx (removed by operation) showing a large carcinomatous growth of the arytenoid cartilage.

Dr. WATSON WILLIAMS showed Models of Operations for Pansinusitis.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 27th, Dr. EDMUND CAUTLEY being in the chair.

Dr. CECIL E. FINNY described a case of Duodenal Ulcer in a child, aged two months, terminating in perforation, and showed the specimen.—In the discussion Dr. CAUTLEY said that although such ulcers gave rise to pyloric spasm and the pylorus was constricted after death, yet there was no evidence of any distinct hypertrophy of the muscle of the pylorus, and this was in favour of the view that pyloric spasm did not cause hypertrophy. Another striking feature was the absence of definite evidence of pain.—Mr. W. MILNER BURGESS asked whether there was any suspicion of diphtheria in the case, to which Dr. FINNY replied in the negative.

Dr. CAUTLEY showed two specimens of Congenital Morbus Cordis.—Dr. G. CARPENTER also showed a specimen. In his case the child had never been blue at any time.

Mr. DUNCAN C. L. FITZWILLIAMS showed a case of Congenital Scoliosis, probably due to the development of an incomplete vertebra, and gave a *résumé* of similar cases of the kind.

Dr. CARPENTER showed specimens from a case of Congenital Dilatation of the Colon in a child aged six months. The child had been constipated from birth and the colon contained hard fæcal lumps. The specimens showed the great hypertrophy of the wall of the colon and illustrations drawn to scale comparing the microscopical appearances with those of a normal gut were passed round.—Dr. CAUTLEY referred to a case under his own care which died at the age of eight weeks. The abdomen was distended, especially across the upper part. The stools were dark brown and of the consistence of wet sand. There were no scybala. A circular perforation was found eight inches above the anus. He thought that in congenital cases there were not usually fæcal masses but only semi-solid contents. He asked whether Dr. Carpenter had considered the possibility of treating such cases by appendicostomy and careful irrigation to allow the colon to contract.—Dr. F. W. HIGGS mentioned a similar case, now four years old, in which treatment had so far been successful. He thought that the chief danger was the occurrence of stercoral ulcers.—Dr. F. PARKES WEBER remarked that the hyperplasia of the elastic tissue had frequently been found and that it had been suggested that the muscular hypertrophy was compensatory to this. Some of the cases certainly lived for a long time. He thought that the patients were at their best when scybala were present.—Dr. CARPENTER, in reply, stated that having been unsuccessful in treating another case by operation he did not adopt that means for this one. Although the child died he did not think surgical interference would have done any good.

Mr. H. M. RIGBY showed a case of Ectopia Vesicæ in a child, aged 14 months, treated by implantation of the ureters into the rectum. The operation was done extra-peritoneally. The child was now able to control the passage of urine.—Mr. HUGH LETT congratulated Mr. Rigby on the result and referred to a number of cases in which operation had at a meal, there has been a show of sugar in the urine, whilst after a moderate quantity, there has been none. Two large helpings of meat, in other words, might give rise to an appearance of sugar when one might fail to do so. This agrees with results that I notice recorded showing the effects of the ingestion of meat on the elimination of sugar in experimental pancreatic diabetes. If reference be made to Hill's "Recent Advances in Physiology and Bio-chemistry," 1906, p. 348, it will be found that an experiment on a dog is mentioned in which, in the absence of food, the sugar fell to 0·77 gramme in the 24 hours, and that, after then giving meat, it rose in the first 24 hours to 3·61, and in the next to 6·09.

Allied to the sugar elimination that has its source in a wrong breaking-down of the bioplasmic molecule may, I consider, be classed the

ELIMINATION OF THE ACETONE SERIES OF BODIES.

This constitutes one of the most important matters connected with diabetes, inasmuch as it is through its instrumentality that the fatal termination of the disease is ordinarily brought about. Sugar, in proportion as it is present in the blood, produces toxic effects of various kinds, which may lead indirectly to death, but it does not, in a direct manner, kill. With regard to the acids belonging to the acetone series, however, the same cannot be said. Their effect in the blood is to interfere with the performance of one of the necessary functions of life.

The continuance of life is dependent upon the elimination of the carbon dioxide produced as a result of vital activity. The sodic carbonate, and, to a certain extent, the sodic phosphate, are the cardinal agents for conveying the carbon dioxide from the tissues to the lungs. If, through any abnormality, there should be an entry of acid into the blood, establishing what is known as a state of acidosis, the alkaline base will be appropriated by it, and thence be prevented contributing to the transport function, as normally designed it should do.

With such circumstances present, and with the acidosis condition growing in intensity, as it will proceed to do, unless it should happen, as where the diabetic state has not attained too advanced a stage, to prove susceptible of being checked, death must sooner or later prove an inevitable result. For vital activity, as for enzyme activity, it is necessary that the products of change should become removed. Their accumulation leads to a stoppage of action, and the issue in connexion with diabetes resolves itself into a question of when the non-removal has attained a sufficient height to reduce the occurrence of action to a point that is no longer consistent with the continuance of life. If, preparatory to this stage being actually reached, a fresh power be given to the blood to take up carbon dioxide, as by the intravenous injection of a sodic carbonate solution or the ingestion of it by the mouth, a speedy restoration of activity temporarily, but unfortunately only more or less temporarily, ensues.

The view here detailed was brought forward by me in an article, published in THE LANCET in 1902,[3] entitled

"ON THE ACETONE SERIES OF PRODUCTS IN CONNEXION WITH DIABETIC COMA."

In this article I state that "writers speak of the altered constitution of the blood by the reduction of its alkalinity as the cause of the coma connected with acidosis and refer the result to the effect of the altered condition of the blood on the tissues of the body. This, however, amounts only to an assertion which gives no insight into the actual pathogeny of the coma." I then open out the view I have mentioned, and in what has preceded, reference is distinctly made to its having been discovered that, in connexion with the acidosis, a great fall in the carbon dioxide content of the blood has been observed. Not long after the article was published, exception was taken by Dr. A. P. Beddard, Dr. M. S. Pembrey, and Dr. E. I. Spriggs to the view I had announced, and they have based their conclusions upon the meaning they give to the fall of carbon dioxide in the blood noticed in their experiments. I will avail myself of this opportunity to give an answer to what they have said.

They have furnished an elaborate series of experiments which, judging from appearances, may be credited with having been carried out in a commendably careful and painstaking manner. These experiments, however, throw no additional light upon the subject. They simply give confirmation and precision to what had been ascertained before, rendering it quite evident that the acidosis in diabetes is attended with an advancing fall in the carbon dioxide content of the venous blood, and, secondarily to this, with a fall of it in the pulmonary alveolar air. A major point, in the eyes of the experimentalists, belonging to the matter, is the effect produced upon the blood by the hyperpnœa that shows itself in diabetic coma. I agree with them to the extent that hyperpnœa has something to answer for in connexion with the reduced carbon dioxide content of the blood associated with the coma. It is only naturally to be expected that the exalted respiration should contribute to the reduction that occurs, and the hyperpnœa may be looked upon as constituting an effort of Nature to rectify the defect existing in connexion with tissue respiration, by producing, through reduced carbon dioxide tension in the blood, as favourable a condition as possible for promoting the drawing off of carbon dioxide from the tissues.

The conditions belonging to the blood, however, represent only one side of the question. On the other side, there is the tissue production of carbon dioxide as an act concurrent with life, and the necessity of its removal when formed, in order to sustain the continuance of life. The supply of oxygen and the removal of carbon dioxide are necessary factors in connexion with vital activity. Arrest either operation, and vital activity will cease. To give greater security to life, the mechanism of respiration is brought into concerted action with the demand existing for its functional activity. Does anyone say that exalted respiratory action is not induced by a deficient supply of oxygen on the one hand, or a defective removal of carbon dioxide on the other? By a stimulus generated within the body by the existence of either of these conditions, a response is called forth from the respiratory nerve centre, which leads automatically to the result that follows. The recent work of Haldane and Priestley stands in accord with this view, and it is supported by the still later work of Hill and Flack.

According to my opponents, however, things are to stand on a different basis, and a new factor is gratuitously invoked, holding a place altogether outside the realm of respiratory action. Through the prolonged acidosis, they suggest that the protoplasm of the cells is made more sensitive to the stimulating influence of any acid body produced during metabolism, and thus, by the direct action of acid, the diabetic coma becomes evoked. To quote their own words, they say:—"It is suggested that the following process is taking place in the nerve-cells of the medulla: the decreased 'reactivity' of the protoplasm of the cells due to the prolonged acidosis renders their reaction more easily disturbed by, and therefore makes them more sensitive to, the stimulating influence of any acid body, including carbon dioxide and other acids produced during metabolism."[4]

Now, no need exists for going outside respiratory action and bringing in a vague, unsubstantiated, extraneous explanation of the kind here offered. The effect of acidosis is to lessen the carbon dioxide transport service performed by the sodic carbonate and sodic phosphate of the blood in proportion to the extent to which the base of these salts becomes appropriated by the acids present. Carbon dioxide is constantly being produced as a result of living action, and I think no one will contend that it does not require to be removed *pari passu* with its production. Observation shows that in enzymic and living action the effect of retention of the products generated is to inhibit, in proportion to their retention, the continuance of action, and thus, in the case under consideration, to slow down the production of carbon dioxide. This is the essential point connected with the matter, and to it the experimentalists referred to have given no attention, thereby, I consider, placing themselves upon false ground by taking too narrow a view of the subject. Their work has been limited to a study bearing on the blood, which only plays a secondary part by effecting the removal of the carbon dioxide produced, and, obviously, if the alkaline bases of it are placed in a position to be unable to contribute to the removal of the carbon dioxide, the production of it must be interfered with, and the amount entering the blood lowered, as is found to be the case in advancing acidosis. I do not consider that what is said about the blood in diabetic coma still possessing in the circumstances named some absorbing power over carbon dioxide can be taken to invalidate the considerations depression bordering on melancholia. The use of local anæsthetics for tooth extraction has grown very common and is responsible for much post-operative sepsis, gangrene, and necrosis. All must be familiar with cases of neuroses or neuritis due to oral sepsis. I will not enumerate all the remote infections and results of toxæmias due to the same cause, but I trust the discussion will educe many important and interesting clinical experiences.—Dr. G. LOVELL GULLAND thought there was a danger of confusing oral sepsis with the results of bad teeth present. A great many of the evils were due to the latter, e.g., imperfect mastication. The risk of infection of the stomach was much less in healthy conditions when the hydrochloric acid was present in its normal amount, but where there was a deficiency of acid, there was no inhibition to the growth of organisms, and hence gastritis might result. Mouth breathers were specially liable to suffer from oral sepsis. He had no belief in the connexion between oral sepsis and pernicious anæmia; this disease usually commenced after middle life when the mouth was as a rule perfectly clean.—Dr. GEORGE M. ROBERTSON said that he always paid great attention to the condition of the mouth in his cases. There was a lessened resistance to the invasion of organisms in the insane; thus tuberculosis and puerperal fever were more common amongst them. The opsonic index was lower in the insane than in average persons. Lunatics were very susceptible to the toxins which produced cell degeneration as well as nerve fibre degeneration. They were especially susceptible to alcohol which was the touchstone of mental equilibrium. Toxins might pass along the lymphatics of the fifth nerve and so might produce mental disturbance. There was a constant absorption of small amounts of toxins from the mouth and these might exert a most deleterious influence. In dementia præcox the tongue was not much used and oral sepsis was well marked in such cases. He thought that a dentist should always be one of the staff in asylums.—Mr. ALEXANDER MILES alluded to the extreme importance of attention to the teeth in the treatment of syphilis. Affections of the mucous membrane were very severe in bad cases of oral sepsis. He had found that peroxide of hydrogen was the best means of cleansing such mouths. He had noted a marked influence which mercury had in women as contrasted with men, the latter being salivated after from seven to ten days' inunction.—Mr. A. A. SCOT SKIRVING thought the necrosis of the jaw which followed the use of local anæsthetics might be due to want of care in sterilising the syringe and the mucous membrane. He would like to know whether dentists employed strict antiseptic precautions.—Dr. JAMES CARMICHAEL said that he had seen many evils resulting from oral sepsis, and especially in children. The affection of the lymphatic glands was a most important sequela and depended almost entirely on some condition in the mouth or naso-pharynx. He advised a careful examination of the mouth and repeated and periodic visits to the dentist.—Dr. J. S. FOWLER said that chronic cough in children was usually due to pharyngitis and might be relieved by attention to the teeth. In the septic condition of the mouth in infants much harm was often done by attempting to cleanse the mouth and he advised rather attention to sterilising the food.—Dr. NORMAN WALKER asked whether when the medical man found evidence of syphilis in a patient who required dental treatment he should communicate his diagnosis to the dentist.—Dr. BYROM BRAMWELL alluded to the direct communication between the ear and the mouth and to the reflex gastro-intestinal and general disturbances which were set up by decayed teeth. These might be due to absorption of toxins from the teeth and gums or might be due to defective teeth leading to faulty mastication or to the pain from carious teeth. He never could accept Dr. William Hunter's views because in many cases there was no chance of oral sepsis, the teeth having gone. The glossitis which was often present in pernicious anæmia was probably due to the same cause which induced the disease. He had commenced to treat these cases with arsenic so long ago as 1877.—Mr. GEORGE L. CHIENE said that local anæsthetics might contain a fairly large proportion of carbolic acid and this, when injected into a very dense tissue, was likely to induce sloughing.—Mr. J. S. FRASER said that in an examination of over 2000 mouths it was very rare to find a perfect set of teeth. He had noted that the mucous membrane under dentures was often very much inflamed and in conditions of oral sepsis he had seen the mucous membrane of the throat and pharynx congested and acute tonsillitis and peritonsillar abscesses were frequent.—The PRESIDENT said that the toilet of the mouth was of the greatest importance, especially in children. He preferred a solution of chlorate of potassium to carbolic lotions as a mouth purifier. He had treated an elderly lady for melancholia; when three teeth which were suppurating at the roots were removed she recovered her mental health. The sepsis had affected her nervous system.—In reply, Mr. GUY said that it would be wise for the dentist to meet the medical man in consultation in such cases as Dr. Norman Walker had referred to. Quite apart from oral sepsis, a large number of teeth might be functionless and so gastric disturbances might arise from faulty mastication. Out of 10 or 12 cases of pernicious anæmia which he had examined only one had a septic condition of the mouth. Of all parts of the body he thought that the alveolar ridges were the least suitable for the injection of local anæsthetics on account of their denseness. The character of the anæsthesia was here largely due to pressure and this must of necessity in a large number of cases be followed by necrosis. He thought that it was better to extract than to stop the teeth in children of the masses. He recommended for cleaning the teeth chalk used in considerable quantity, much more than was usually employed, together with a little clove oil and saccharin which was an excellent antiseptic. After extraction an antiseptic lotion (as carbolic acid and carbonate of soda) should invariably be used. Women's mouths were as a rule much dirtier than those of men.

---

[3] THE LANCET, July 12th, 1902, p. 64 et seq.

[4] Journal of Physiology, 1908, vols. xxxvii. and xli.

Dr. BYROM BRAMWELL gave a Lantern Demonstration of a series of cases of unusual interest: 1. Typical Lymphatic Leukæmia developing at the remarkable age of 77 years. 2. Hæmorrhage extending from the top of the Pons Varolii to the bottom of the Medulla Oblongata; death a month after the occurrence of the first symptoms; patient not unconscious until just before death. 3. Acute Encephalitis involving the brain and pons Varolii; numerous micro-organisms in the affected tissues. 4. Aneurysm of Basilar Artery; rupture 90 hours before death; (?) previous rupture seven weeks before death; mitral stenosis. 5. Typical Pseudo-hypertrophic Paralysis with most remarkable changes (apparently artefacts) in the spinal cord. 6. Tumour of the Pituitary Body and Infundibulum with most marked Diabetes Insipidus; paralysis of both third nerves, &c.; other tumours in the groin, thyroid, pancreas, and kidney.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on Nov. 20th, Dr. A. R. PARSONS, the President, being in the chair.

Sir JOHN W. MOORE exhibited specimens of a Double Mitral Lesion. A girl, aged 14 years, was admitted to the Meath Hospital on August 11th, 1908. She died on Sept. 14th. She had been seriously ill for five weeks before her admission, complaining of pain about her heart and of short breath. Her weight was 6 stones and ½ pound. Physical examination showed that she was suffering from the effects of rheumatic endocarditis, unmistakeable evidence that compensation had failed being present. As to the heart itself, a double murmur was audible at and near the seat of impulse, a presystolic murmur with slight valvular thrill indicating mitral obstruction, while a systolic murmur heard over an extensive area from the apex beat to the left side and back indicated mitral leakage. The latter murmur was conducted upwards towards the aortic area, where it was faintly heard, but it quite failed to reach the carotids by convection. There was, therefore, no clinical evidence of any lesion of the aortic valves. The patient made satisfactory progress through rest in bed and on three-grain doses of citrate of iron and quinine, and compensation seemed to be almost restored, when on Sept. 11th she suddenly became unconscious and vomited freely. She soon recovered consciousness in part, that is in two hours from the seizure, but vomiting recurred at intervals during the day. When she at a meal, there has been a show of sugar in the urine, whilst after a moderate quantity, there has been none. Two large helpings of meat, in other words, might give rise to an appearance of sugar when one might fail to do so. This agrees with results that I notice recorded showing the effects of the ingestion of meat on the elimination of sugar in experimental pancreatic diabetes. If reference be made to Hill's "Recent Advances in Physiology and Bio-chemistry," 1906, p. 348, it will be found that an experiment on a dog is mentioned in which, in the absence of food, the sugar fell to 0·77 gramme in the 24 hours, and that, after then giving meat, it rose in the first 24 hours to 3·61, and in the next to 6·09.

Allied to the sugar elimination that has its source in a wrong breaking-down of the bioplasmic molecule may, I consider, be classed the

ELIMINATION OF THE ACETONE SERIES OF BODIES.

This constitutes one of the most important matters connected with diabetes, inasmuch as it is through its instrumentality that the fatal termination of the disease is ordinarily brought about. Sugar, in proportion as it is present in the blood, produces toxic effects of various kinds, which may lead indirectly to death, but it does not, in a direct manner, kill. With regard to the acids belonging to the acetone series, however, the same cannot be said. Their effect in the blood is to interfere with the performance of one of the necessary functions of life.

The continuance of life is dependent upon the elimination of the carbon dioxide produced as a result of vital activity. The sodic carbonate, and, to a certain extent, the sodic phosphate, are the cardinal agents for conveying the carbon dioxide from the tissues to the lungs. If, through any abnormality, there should be an entry of acid into the blood, establishing what is known as a state of acidosis, the alkaline base will be appropriated by it, and thence be prevented contributing to the transport function, as normally designed it should do.

With such circumstances present, and with the acidosis condition growing in intensity, as it will proceed to do, unless it should happen, as where the diabetic state has not attained too advanced a stage, to prove susceptible of being checked, death must sooner or later prove an inevitable result. For vital activity, as for enzyme activity, it is necessary that the products of change should become removed. Their accumulation leads to a stoppage of action, *and the issue in connexion with diabetes resolves itself into* a question of when the non-removal has attained a sufficient height to reduce the occurrence of action to a point that is no longer consistent with the continuance of life. If, preparatory to this stage being actually reached, a fresh power be given to the blood to take up carbon dioxide, as by the intravenous injection of a sodic carbonate solution or the ingestion of it by the mouth, a speedy restoration of activity temporarily, but unfortunately only more or less temporarily, ensues.

The view here detailed was brought forward by me in an article, published in THE LANCET in 1902,[3] entitled

"ON THE ACETONE SERIES OF PRODUCTS IN CONNEXION WITH DIABETIC COMA."

In this article I state that "writers speak of the altered constitution of the blood by the reduction of its alkalinity as the cause of the coma connected with acidosis and refer the result to the effect of the altered condition of the blood on the tissues of the body. This, however, amounts only to an assertion which gives no insight into the actual pathogeny of the coma." I then open out the view I have mentioned, and in what has preceded, reference is distinctly made to its having been discovered that, in connexion with the acidosis, a great fall in the carbon dioxide content of the blood has been observed. Not long after the article was published, exception was taken by Dr. A. P. Beddard, Dr. M. S. Pembrey, and Dr. E. I. Spriggs to the view I had announced, and they have based their conclusions upon the meaning they give to the fall of carbon dioxide in the blood noticed in their experiments. I will avail myself of this opportunity to give an answer to what they have said.

They have furnished an elaborate series of experiments which, judging from appearances, may be credited with having been carried out in a commendably careful and painstaking manner. These experiments, however, throw no additional light upon the subject. They simply give confirmation and precision to what had been ascertained before, rendering it quite evident that the acidosis in diabetes is attended with an advancing fall in the carbon dioxide content of the venous blood, and, secondarily to this, with a fall of it in the pulmonary alveolar air. A major point, in the eyes of the experimentalists, belonging to the matter, is the effect produced upon the blood by the hyperpnœa that shows itself in diabetic coma. I agree with them to the extent that hyperpnœa has something to answer for in connexion with the reduced carbon dioxide content of the blood associated with the coma. It is only naturally to be expected that the exalted respiration should contribute to the reduction that occurs, and the hyperpnœa may be looked upon as constituting an effort of Nature to rectify the defect existing in connexion with tissue respiration, by producing, through reduced carbon dioxide tension in the blood, as favourable a condition as possible for promoting the drawing off of carbon dioxide from the tissues.

The conditions belonging to the blood, however, represent only one side of the question. On the other side, there is the tissue production of carbon dioxide as an act concurrent with life, and the necessity of its removal when formed, in order to sustain the continuance of life. The supply of oxygen and the removal of carbon dioxide are necessary factors in connexion with vital activity. Arrest either operation, and vital activity will cease. To give greater security to life, the mechanism of respiration is brought into concerted action with the demand existing for its functional activity. By a stimulus generated within the body by the existence of either of these conditions, a response is called forth from the respiratory nerve centre, which leads automatically to the result that follows. The recent work of Haldane and Priestley stands in accord with this view, and it is supported by the still later work of Hill and Flack.

According to my opponents, however, things are to stand on a different basis, and a new factor is gratuitously invoked, holding a place altogether outside the realm of respiratory action. Through the prolonged acidosis, they suggest that the protoplasm of the cells is made more sensitive to the stimulating influence of any acid body produced during metabolism, and thus, by the direct action of acid, the diabetic coma becomes evoked. To quote their own words, they say:—"It is suggested that the following process is taking place in the nerve-cells of the medulla: the decreased 'reactivity' of the protoplasm of the cells due to the prolonged acidosis renders their reaction more easily disturbed by, and therefore makes them more sensitive to, the stimulating influence of any acid body, including carbon dioxide and other acids produced during metabolism."[4]

Now, no need exists for going outside respiratory action and bringing in a vague, unsubstantiated, extraneous explanation of the kind here offered. The effect of acidosis is to lessen the carbon dioxide transport service performed by the sodic carbonate and sodic phosphate of the blood in proportion to the extent to which the base of these salts becomes appropriated by the acids present. Carbon dioxide is constantly being produced as a result of living action, and I think no one will contend that it does not require to be removed *pari passu* with its production. Observation shows that in enzymic and living action the effect of retention of the products generated is to inhibit, in proportion to their retention, the continuance of action, and thus, in the case under consideration, to slow down the production of carbon dioxide. This is the essential point connected with the matter, and to it the experimentalists referred to have given no attention, thereby, I consider, placing themselves upon false ground by taking too narrow a view of the subject. Their work has been limited to a study bearing on the blood, which only plays a secondary part by effecting the removal of the carbon dioxide produced, and, obviously, if the alkaline bases of it are placed in a position to be unable to contribute to the removal of the carbon dioxide, the production of it must be interfered with, and the amount entering the blood lowered, as is found to be the case in advancing acidosis. I do not consider that what is said about the blood in diabetic coma still possessing in the circumstances named some absorbing power over carbon dioxide can be taken to invalidate the considerations organic disease. The same might be said, too, of choline, but the tests for choline were difficult to carry out clinically. The absence of dextrose which occurred in normal cerebro-spinal fluid was characteristic of many cases of meningitis. In tuberculous meningitis a lymphocytosis was found, as also in tabes, in general paralysis, and in cerebro-spinal syphilis. Polymorphonuclear leucocytosis indicated an acute inflammatory condition of the meninges. It was possible, by means of lumbar puncture, to classify the various forms of meningitis and to diagnose anomalous forms. The operation helped also to differentiate meningitis from cases of so-called meningism and from uræmia. In a few cases it was possible to diagnose cerebral hæmorrhage from thrombosis or embolism. In no case of cerebral tumour had it helped in diagnosing the actual nature of the lesion, although a few cases were recorded where valuable information had been obtained. As a therapeutic agent lumbar puncture deserved more credit than it received. It did temporary good in probably all cases of meningitis and in some effected a permanent cure. It was a very valuable procedure in cases of increased intracranial pressure. Three cases were cited—cerebral tumour, subacute nephritis, and fractured base of the skull—in which it had led to recovery from coma which would otherwise apparently have proved fatal.—Dr. Thos. Robertson showed: 1. A case of Banti's Disease in a boy. There was a history of anæmia and hæmorrhages. At present there are a slightly enlarged spleen, enlarged liver, persistent jaundice, leukopænia, and anæmia of the chlorotic type. There had been great improvement under arsenic. 2. A case of Paramyoclonus Multiplex in a boy; this was the third case in the same family.—Dr. Arthur J. Hall read a paper on Diabetes Mellitus. He called attention as to whether this disease was increasing or not. In order to clear up this point he had obtained statistics of the Registrar-General for England and Wales and also those of the city of Sheffield. From these it was seen that during the two decades 1887-96 and 1897-1906 the number of deaths from diabetes per 1,000,000 of the inhabitants living had increased from an average of 64 during the first decade to 88 during the second in England and Wales, whilst in Sheffield the increase during the same two periods was from 42 to 66. A further inquiry into the possible explanation of this great increase showed that it had occurred practically in the two sexes, but that the increase was much greater in those whose age at death was above 45 years than in those whose age at death was below. The most marked increase is in those dying between 55 and 75 years of age. From these results it seems probable that whilst there appears to be a slight increase in the number of cases of acute diabetes affecting younger or middle-aged adults, the great increase seen from the Registrar-General's reports is chiefly due to an increased number of cases of diabetes occurring in older people or at least not causing premature death. The subject of treatment of diabetes was then alluded to, particularly the question as to the value of opium or its alkaloids and secretin. Tables showing a series of clinical observations on the effect of opium in numerous cases were exhibited and from these various points were illustrated. In conclusion Dr. Hall pointed out that whilst as regards therapeutics of diabetes the profession stands much where it did nearly a century ago, yet the advance in our knowledge of the pathology of the disease has been considerable and the prospect of future clinical application of that knowledge is not without hope.

[4] Journal of Physiology, 1908, vols. xxxvii. and xli.

Æsculapian Society.—A meeting of this society was held on Dec. 4th, Dr. Alexander Morison, the President, being in the chair.—Dr. T. G. Stevens read a paper on the Diagnostic Value of Pain in Gynæcology. He said: Pain is a well-marked symptom in diseases of women but it is often difficult to localise so as to be helpful in diagnosis, so that we often have to neglect pain distribution and rely on physical signs for diagnosis. Visceral pain in general is either (1) deep-seated peritoneal pain, always associated with inflammatory diseases and with malignant growths, is more or less generalised, and elicited by deep pressure; or (2) reflected pain—a skin sensation. The skin can be mapped out into areas corresponding to certain segments in the cord and these areas represent pain corresponding with certain visceral lesions. Inflammatory diseases of the ovaries always give hypersensitiveness to pain in the area supplied by the tenth dorsal nerve; the uterine cervix and lower part of the body correspond to the tenth, eleventh, and twelfth dorsals, and the second, third, and fourth sacrals are particularly connected with the body of the uterus. In connexion with pain in general they must not forget neurasthenia, which is a general lowering of the central nervous system in its powers of bearing and localising pain. Acute pain coming on quite suddenly points to threatened abortion, ruptured tubal gestation, ruptured ovarian cyst, or torsion of the pedicle of an ovarian cyst. Acute pain with a gradual onset is seen in inflammatory diseases developing slowly, such as pelvic peritonitis, gonorrhœa as it spreads to the vulva, infection of Bartholin's gland, and retroverted gravid uterus. Periodic menstrual pain may be premenstrual, coming on two, three, or seven days before the flow and due to congestive dysmenorrhœa. If the pain is with the flow—spasmodic dysmenorrhœa—it is associated with imperfect development of the uterine muscle. Periodic pain may occur without menstruation due to the uterus being undeveloped or to retained menses. Again, periodic pain may be intermenstrual, occurring regularly between each menstrual period, the so-called "middle pain"—the Mittelschmerz, so fully described by the Germans but first described by Sir William Priestley. Chronic pain in the back is nearly always associated with common diseases of women, such as endometritis, retroversion of the uterus, prolapse, impacted fibroid in the uterus, &c. Chronic pain is mostly lateral and, as pointed out by Herman, oftener on the left side. Pain in cancer of the cervix is generally a late symptom and it is quite common to see patients with inoperable cancer with little or no pain. Simple ovarian cysts usually give rise to no pain, but malignant ovarian growths nearly always give rise to pain due to implication of the peritoneum. In uterine fibroids, especially small ones, pain as a rule is absent, but pain may be marked if the fibroid gets impacted in the pelvis or compresses the neck of the bladder or rectum. In tubal gestation pain often is a premonitory symptom of rupture. Pain of an intermittent character, deep-seated in the pelvis, in a woman who has missed a period is very suggestive of a tubal gestation, due to the distension of the tube from hæmorrhage around the embryo.

Glasgow Medico-Chirurgical Society.—A meeting of this society was held on Nov. 20th, Dr. Robert Jardine, Vice-President, being in the chair.—Mr. Cuthbert S. Wallace delivered an address on Some Problems connected with Diseases of the Prostate. The internal sphincter was, he said, the true bladder sphincter. By means of lantern slides he pointed out that in advanced cases of prostatic enlargement an explanation of the symptoms was easy, but that in early stages there was little physical alteration to account for symptoms. He considered that, in this country at least, chronic prostatitis was rare and that most of the symptoms were those that belonged to sexual neurasthenia. The appearances of chronic inflammation were wanting in the specimens which he had examined. The best case of prostatic enlargement for operation was that with large resistant prostate with well-marked symptoms. The suprapubic route was best. The small hard prostate was best left alone if the symptoms were not marked and if attacked the low route was best. The signs of carcinoma were a small hard prostate unilobular bulging of the rectum, a plaque-like extension into the inter-vesicular area or into the base of the bladder, and a thickened condition of the urethra. Hæmorrhage was not common; pain might be extreme. Other symptoms were the same as in simple enlargement, except that the duration of illness was usually less. He referred to the possibility of diagnosing the condition while the cancer was still confined to the gland. Regarding the possibility of diagnosing carcinoma while still confined to the gland, it was pointed out that the most remarkable symptom—viz., the upward extension on to the bladder base—was no good, as when such had occurred it was obvious that the growth was already outside the gland. Also there was no doubt that metastasis occurred in distant parts, though there was little local infection. The neighbouring glands might escape while the pleura was infected. He referred to cases illustrating the fact that a patient might live in fair comfort for three years after the microscopic diagnosis of cancer. Even piecemeal removal of the gland behind the urethra was successful in relieving symptoms, though useless from a curative point of view. The operation of real, total prostatectomy would take its place in the future, though the mortality was bad at present. It was

There are foods of this kind to be obtained from establishments in London, whose praiseworthy and successful efforts have been brought to bear to produce it. Unfortunately another side presents itself that nowhere escapes being encountered, and here the foods contain a varying amount of starch, which may even, in some cases, be found to reach that belonging to the bread-stuff food in common use. A moment's reflection will suffice to show that no proper knowledge can be obtained with reference to the matter under consideration in the absence of a knowledge of the actual state of the food consumed by the patient.

Generally, at an early stage of the disease (children excepted), the effect of putting the patient on a restricted diet is not attended with the production of an appearance of the acetone bodies. At a later stage, in the case where dieting has not been in a proper manner carried out, and where sugar has been all along voided, the effect of cutting off carbohydrate food may be expected to lead to a certain amount of show of the acetone bodies. Afterwards, when, as a result of the dieting, the sugar is reduced and subsequently removed; the acetone bodies may also, in the course of a little time, be counted upon to make their disappearance.

In a case of a somewhat advanced nature, where the acetone bodies have already become present, the change of diet leads to a certain amount of augmentation of them, but the augmentation that shows itself does not afterwards intrinsically tend to proceed further. In fact, the future issue is dependent upon the stage of disease that has been reached. If too advanced to admit of rectification, the disease and its associated acidosis make headway together till it happens that the acidosis becomes greater than the power of the system to withstand, and death ensues. If not sufficiently advanced inevitably to lead to this issue, and the case should be of a suitable type subsequently to yield, the sugar, as time goes on, may be found to become more and more reduced and ultimately to disappear, and, with this, the acetone bodies may be expected to follow a similar, but more tardy, course. In this way, from what may have seemed at the beginning a very unpromising state, progress may be made through the instrumentality of the influence exerted by the food in bringing down the sugar, for this is at the root of the change induced, to the attainment of a condition in which a totally new aspect is given to the life tenure prospects.

There have been those who have deprecated the strict diet in the treatment of diabetes on account of the relation that has been referred to between acetonuria and the exclusion of carbohydrate from the food. The effect of the acids of the acetone group in leading up to coma should, it has been suggested, demand first consideration and prohibit the cutting off of carbohydrate food. If such a *maxim* were acted upon, diabetics would stand, as indeed they did in former times before dieting was applied as it is now, in a very bad position. It is within my own recollection to have known that the outlook in diabetes was vastly different from what it is now. Experience shows that the

WAY TO GET RID OF THE ACETONE BODIES

is to bring the sugar down, and if this is not done, all that can be looked for is that they will go on increasing. The sugar in the system, by its direct toxic influence, may, be regarded as a main factor in causing the acidosis in the first place to set in, and then to grow. In a case where sugar and the acetone bodies have existed, and, by cutting off carbohydrate, have become removed, as long as sugar-free urine is maintained, there is no return of the acetone bodies. Let sugar reappear by relaxation of diet, and a return of the acetone bodies may be expected to likewise occur. I could cite many cases where such has happened, and have further observed a renewed disappearance on a return to the proper food.

The effect of what I have stated is to suggest that, in ordinary cases, the cutting off of carbohydrate should at once be put into force for the purpose of dealing with the acetone bodies. At the same time, however, I do not mean to say that cases may not now and then present themselves in which it would be unwise to adopt such a course. In extreme cases, where the patient is on the brink of the supervention of coma, a little increase in the acidosis existing may suffice to turn the scale and bring about a fatal issue. The sudden withdrawal of carbohydrate has been seen to lead to such increase, and thereby a demand is created for the exercise of judgment in connexion with the course to be adopted.

The frailness of the condition as a whole, in the circumstances under consideration, has also to be taken into account. We know how easily, through the general state, the acetone bodies may be increased. A severe attack of migraine, for instance, may send them up, and influenza, pneumonia, &c., may do so sufficiently to suddenly bring about the supervention of coma. There is too much instability of system to withstand the influence of sudden change, and thus an added condition presents itself to that emanating from the direct action of the cutting off of carbohydrate on the dissociation process, which tends to promote the augmentation of the acetone bodies passing into the blood.

I have entered at some length into the question of acidosis and its bearings on food treatment in diabetes in my work on "Carbohydrate Metabolism and Diabetes," and at pages 117-22 will be found what I have said upon the subject.

Mal-application of carbohydrate food within the system constitutes the essential error existing in diabetes, and what is wanted to be effected by

TREATMENT

is to bring conditions back into line for it to be again turned to proper account. In a state of health, carbohydrate is taken and can be followed to the seat of absorption belonging to the alimentary canal. Here, however, it becomes lost to view. Neither the blood nor the urine affords evidence of the absorption that manifestly occurs. Physiologists say, notwithstanding they are confronted with this fact, that passage of the absorbed sugar into the blood occurs, but that its removal by the tissues prevents its coming into view. This constitutes an assumption which is not only not supported, but is opposed by experimental evidence. In former times, when it was held that a tangible disappearance of sugar took place in the passage of the blood from the arteries to the veins, some show of foundation presented itself for the entrance of sugar into the circulation, but now that it is admitted that no such disappearance is to be recognised, the entrance could only lead to presence in the blood and outflow with the urine, which represents the state of things existing in diabetes. For sugar to reach the circulation without showing itself in the urine, it would be necessary for a capacity to exist for effecting its instantaneous removal, and that no such capacity is present is made evident by the experimental injection of minimum quantities intravenously.

To keep sugar out of the urine, it must be kept out of the circulation, and any hypothesis explanatory of the procedure connected with the physiological application of carbohydrate must be based upon this principle. To regard it as falling within the natural course of events that the food carbohydrate should pass through the circulation to the tissues in the form of sugar is tantamount to taking the pathological as representative of the physiological state, seeing that it is just such passage which is productive of diabetes.

To escape from diabetes, the food carbohydrate must not be allowed to reach the general circulation in the form of sugar. This is

THE BASIS TO PROCEED UPON,

and the view that has been enunciated in these lectures fits in with it. It is contended that the absorbed sugar becomes dealt with at the seat of absorption, and, in company with the products derived from protein digestion, is, by the bioplasmic action attending lymphocyte growth, put into an elaborated state. The process falls under the denomination of assimilation, and when the sugar is thus disposed of and incorporated as a constituent of the large newly-constructed molecule, it is placed in a position to be secure from running off with the urine during the transit of the blood through the kidney.

Looked at in this way, the error in diabetes consists of a faulty assimilation of the sugar absorbed from the alimentary canal. Digestion prepares for absorption, and assimilation, which follows immediately upon it, puts the absorbed digestion products into an elaborated state, in which form they pass through the thoracic duct into the blood and there constitute the pabulum from which the tissues draw their nutrient supply. This agrees with what used to be the idea entertained by physiologists with regard to the course taken

Reviews and Notices of Books.

The Origin of Vertebrates. By W. H. GASKELL, M.D. Cantab., F.R.S. London: Longmans, Green, and Co. 1908. Pp. 537. Price 21*s.* net.

FOR 20 years the papers from which this book has been compiled have been published at short intervals, and to their author it is a subject of wonder and regret that they have not been criticised as are other papers of a like calibre. That they have not been so criticised does not imply want of notice, for probably few scientific papers have been more extensively or fully read, but it does seem to imply that the leaders of morphological thought have realised that they must adopt one of two courses: (1) allow the essential truth of the theory and at the same time admit that the foundations of embryology as at present taught are unsatisfactory; or (2) ignore the wonderful sequence of morphological researches and deductions because they do not fit in with our present conception of embryology.

It is quite childish to pretend that the importance of the subject does not justify the trouble necessary to expose any fundamental error there may be in the chain of constructive argument and probably the inadequate notice which Dr. Gaskell's papers have received is the greatest tribute that could be paid to him. In trying to be altogether just we must recognise the possibility that critics were waiting until the work was presented as a whole before crushing it or admitting its substantial validity, though against this it has to be realised that there is no living morphologist who has devoted 20 years to the study of the origin of vertebrates or who could fairly criticise the subject from every point of view. To those who have not read the original papers, most of which appeared in the *Journal of Anatomy and Physiology*, we suggest that after reading the introduction they begin the book with Chapter XIV. on page 455. This is on the principles of embryology and if, after reading it, they are convinced that the epiblast and hypoblast could not change places with one another as the theory demands they need go no farther. If, however, any suspicion of the sanctity of the three germinal layers arises the constructive part of the book should be read with the care which it undoubtedly deserves.

The author's object is to show good reasons for deriving the vertebrates directly from the arthropods, and that the central canal of their brain and spinal cord is the arthropod's alimentary canal; that the infundibulum, leading to the pituitary body and pharynx of the vertebrate embryo, is the mouth of the arthropod, while the neurenteric canal represents the more primitive anus. Incidentally the various parts of the invertebrate brain fall into their places, the supra-œsophageal ganglia become the fore brain, the supra-œsophageal commissure the anterior commissure of vertebrates, the infra-œsophageal ganglia become the hind brain, while the parœsophageal connectives are the crura cerebri. So, too, the cephalic stomach of the arthropod becomes the ventricles of the brain, while the fore brain retains its original communication with the olfactory and optic nerves and the hind brain with the nerves concerned in mastication and respiration.

The nearest living arthropod to the vertebrate progenitor Dr. Gaskell regards as the king crab (*Limulus*), a close ally to the trilobites which were so plentiful in Silurian times. The trilobites, sea scorpions, and king crabs are included in the group Palæostraca from which the Crustacea, Arachnida, and Vertebrata were gradually evolved. The earliest vertebrates known are fish without jaws, in this resembling the lamprey, and they first appear in Silurian times. Dr. Gaskell insists that their nearest living representative is not the amphioxus of our orthodox text-books, but ammocœtes, the larval lamprey. Very interesting to the anatomist are the chapters devoted to the evolution of the pineal body, the thyroid body, the notochord and ductless glands; but the author is in harmony with most modern thought in insisting on the importance of the nervous system as the master organ the development of which determines the winners in the struggle for existence.

Whatever the line of descent of the vertebrates may be there can be no doubt as to the wonderful deductive powers of the author or the patience and skill of his 20 years' research. What the plain man will ask is, "How much is he keeping back?" and "Is he, like some brilliant theorists, using only the facts which support his case?" As to this we, like the author, must await the verdict of the experts. If they know anything beyond the embryological difficulty which makes his case impossible it can still be said, though the wonder is that knowing it they have not said it already.

Military Hygiene: a Manual of Sanitation for Soldiers. By Lieutenant-Colonel R. H. FIRTH, R.A.M.C. London: J. and A. Churchill. 1908. Pp. 299. Price 3*s.* 6*d.* net.

THIS comprehensive little work has been presented by the author in order to explain the bearing of the principles necessary for the preservation of health. It is especially valuable as, according to the provisions of Army Order 3 of 1908, sanitation is a compulsory subject of examination for promotion to the rank of Captain. The importance of sanitation is at length becoming fully recognised in our army, for it is now manifest how disease will produce absence from the effective ranks, and thus the prevention of disease is synonymous with military efficiency. We entertain our recruits after an examination as to their personal fitness; the aim henceforth should be to retain them, so far as medical science can retain them, in this state of personal fitness. Those in authority must know for this purpose how soldiers should be housed, fed, clothed, and equipped. These details this work undertakes to teach to those concerned, and admirably has it effected its object.

The author commences his subject by a consideration of military morbidity and mortality as influenced by locality, age, and length of service; he shows *inter alia* that the loss due to discharge as invalids is not materially increased by foreign service, although the death-rate is distinctly raised thereby. *En passant*, we see that that class of disease—the venereal—which is so important in the army, is present in its highest ratio in the American army, the British army coming next, whilst the Germans enjoy the greatest freedom from it. The causes of disease are considered, after which Lieutenant-Colonel Firth enters on the subject of the chief preventable diseases of soldiers, including venereal diseases, malaria, dysentery, infectious diarrhœa, cholera, typhus fever, enteric fever, plague, Malta fever, yellow fever, scurvy, and cardiac affections. The principles of the prevention of disease are detailed and here we see the good effects of inoculation against enteric fever admirably portrayed. The agencies by which organised sanitary effort is carried out are then dealt with. Next we come to the points to be considered in enlisting recruits, followed by a chapter on their physical training.

One of the best chapters in the book now follows—viz., that on barracks. This includes matters relating to the site, the disposition of the buildings on the site, the planning of the barrack-rooms, the ablution rooms, the method by which cleansing should be carried out, questions concerning the storage of food, the washing-up of plates and dishes, the latrine accommodation, and especially the consideration of tropical barracks. It closes with

When the setting in of restoration of carbohydrate assimilative power will occur, cannot in any case be predicted. It may be within a few weeks, or a few months, or it may be delayed for a few years. A striking instance of long delay is afforded by the following case of a patient who was 42 years of age when he first came to me on Oct. 14th, 1904. He was then in a very broken-down state and his urine contained 71·4 per 1000 of sugar associated with a certain amount of diacetic acid and acetone. Notwithstanding close attention to a properly restricted diet, the declining sugar did not disappear till the end of about six weeks. On Nov. 18th there was a little sugar present, but on Dec. 3rd there was none. The patient became restored to health and continued on the strict diet till July 28th, 1906, before any sign was afforded of returning assimilative power. Acting upon the indication then presented, three ounces of ordinary wheaten bread per diem were tried and found to be tolerated. At the end of September there were indications of further restoration of assimilative power, and the bread was increased to four and a half ounces per diem without any return of sugar. No further indication of growth of power has since appeared, and the patient, who was last seen on Nov. 14th, 1908, is so far maintaining a perfect state of health with food adjusted to the curtailed carbohydrate assimilative power that he possesses.

The

RETURN OF ASSIMILATIVE POWER IS REVEALED BY UNMISTAKEABLE SIGNS.

These consist of a fall in weight and a bodily feeling of sinking or food want. As long as there is no return of assimilative power, the restricted diet suffices to meet the requirements of the system, and a proper state of equilibrium exists within. Not so, however, when restoration of carbohydrate assimilative power has taken place. Here the restricted diet, as in the healthy person, fails to meet the demands of life and Nature reveals it through the signs that have been referred to. Whilst no carbohydrate assimilative power exists, a supply of carbohydrate cannot be needed by the system. When, however, the power becomes restored, carbohydrate becomes immediately to a proportionate extent wanted—a fact that is plainly shown by Nature's revelations. These revelations, associated with sugar-free urine, may be safely read as meaning the setting in of returning assimilative power, and that action should be taken accordingly. The action needed is the supply at first of a limited amount of starchy food. The urine immediately tells the tale if too much is given. Afterwards, the starchy food must be increased as the restoration of power advances, always keeping the amount given within the boundary line of the power existing.

The

EXTENT TO WHICH THE ASSIMILATIVE POWER BECOMES RESTORED

varies greatly in different cases, but in each a sharply defined line throughout the progress exists. In a certain number of instances it becomes restored completely, which implies that the attack of diabetes has been in a direct manner thrown off. It is usual for it to become restored up to a certain point, and there to remain more or less fixed. If a patient, in the presence of these circumstances, should take carbohydrate food beyond the power existing to assimilate it, and thus give rise to a renewal of the transit of sugar through the system, the assimilative power will again decrease, and should a marked amount be allowed to pass through, the condition may be expected in the course of time to become as bad as it was at the beginning, if not even worse. It is in this way that relapses take place, and for the maintenance of a satisfactory state, the maintenance of sugar-free urine constitutes a *sine quâ non*. The sugar that pervades the system as an effect of the disease thus becomes a paramount factor in relation to issue.

The class of case upon which the remarks I have made have been based is that belonging to the "alimentary" type, which is the common form met with in patients above the middle period of life. Ordinarily in young subjects the case at the beginning runs upon the lines that have been depicted, but later, on account of the existence of an inherent progressiveness, the treatment which at one time succeeded in keeping things right fails any longer to do so, and a relentless onward march ensues. Progress into the "composite" or bad type is not always to be averted in later years, but it is very much accelerated by improper dietetic management, and when the advanced stage is reached, the case, on account of sugar being derived from tissue disintegration as well as from food, is naturally no longer susceptible of being influenced by diet in precisely the same manner as whilst belonging to the "alimentary" type. Unfortunately for the training of the student, the class of case that is usually met with in the hospital belongs to the "composite" and not to the "alimentary" type.

It is something to achieve to be able to effect a restoration of assimilative power that will permit of a certain quantity of starchy food being taken. The patient is placed in a much less difficult and much more comfortable position. I first hinted at the recovery of the power in the supplementary Croonian lecture delivered by me at the Royal College of Physicians of London in November, 1897,[5] and subsequently, in a communication published in THE LANCET in 1900[6] under the title of "Differentiation in Diabetes," I entered into a detailed consideration of the matter. The subject has also been fully dealt with in the section on diabetes contained in my work on "Carbohydrate Metabolism and Diabetes," 1906, and notwithstanding the light that the information throws upon the whole question concerned, and the satisfactory basis that it supplies in connexion with the application of treatment, I have not seen that the attention it deserves has been given to it.

It follows from what has preceded that the physician is dependent for success in treatment upon the character of the food that is available for his patient. Through the incentive that has been created for meeting the demand that has arisen for a pure and palatable

DIABETIC BREAD-STUFF,

endeavours have been successfully applied in the direction needed, and there are now establishments in London from which the diabetic can reliably obtain his required supply. At the same time, there are foods produced and sold under the name of diabetic foods that are not entitled to receive this designation, and they constitute the source of a great amount of harm. Many are no better than ordinary domestic foods, and others contain too much carbohydrate to permit of its being possible, in the usual run of case, to get rid of the sugar from the urine.

In illustration I may refer to some foods that fell under my notice about a year ago in the following way. In connexion with the case of a boy patient, a physician from Paris on a visit to London was, at the request of an uncle residing in France, permitted to see the patient, and on his return home dispatched a parcel of diabetic foods obtained from a well-known supply establishment in Paris. Here are the figures showing the percentage of carbohydrate expressed as starch that they contained in the water-free state, into which, for apt comparison, all foods should be brought previously to analysis:—

	Carbohydrate as starch.
Gluten flour	72·0 per cent.
,, bread	50·0 ,,
,, biscuit	54·7 ,,
Granulated gluten	63·9 ,,

Food supplied by Rademann of Frankfurt was referred to when I was speaking of Professor von Noorden's "oat" cure. Samples were obtained from this maker at the early part of the present year, and the figures here given show the percentage of starch present in the articles in the water-free state. An improvement is perceptible upon the figures previously yielded:—

	Carbohydrate as starch.
Diabetic white bread	47·2 per cent.
Diabetic Graham bread	40·8 ,,
Diabetic black bread	41·9 ,,
"D.K." bread	74·5 ,,
Diabetic rusks	46·5 ,,
Diabetic cakes	44·4 ,,
Diabetic meal	62·0 ,,

I have said nothing about drug treatment, and for the reason that I know of nothing that by itself exerts a direct and immediate arresting influence over the elimination of sugar. In reality, something is wanted to set metabolism right, in like manner as it is set right by the thyroid extract two heads, Ectoparasites and Endoparasites. The former or external parasites are worthy of notice, mainly because of their possible rôle in the life-history of some of the internal parasites. In this section mention is made of the lice that infest grouse, and the flies, fleas, mites, and ticks which are to be found from time to time on this bird. The endoparasites are of more pathological significance, since some of them are responsible for serious outbreaks of disease. There are several varieties of platyhelminthes which, however, appear to do little harm. Of the nematode worms the strongylus pergracilis is the cause of serious epidemics of Klein's disease. The syngamus trachealis is very rarely found and no disease has as yet been traced to it. Similarly the trichotrachelidæ have one representative which occurs sparingly in the duodenum. Dr. L. Sambon has described a microfilaria in the blood of the grouse; he also with Dr. C. G. Seligmann has recently described a leucocytozoon, one of the hæmosporidiæ, which they found in the blood of a grouse. No disease analogous to the one which is so fatal to turkeys caused by an amœba has been observed in the grouse. The work has not been carried out under the most favourable conditions and the amount of original observations accurately described redounds to the credit of the investigators. We look forward with pleasure to the completed report of the committee, which will appear in due course.

[6] THE LANCET, June 16th, 1900, p. 1706 et seq.

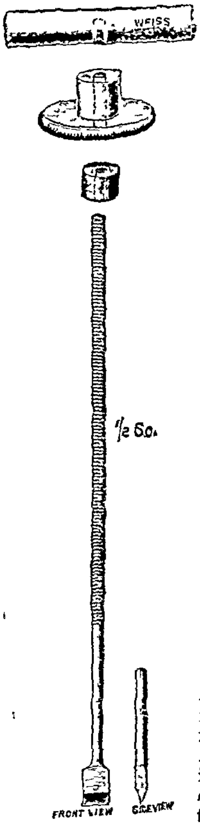
Some Characteristics and Requirements of Childhood. By ALICE RAVENHILL, F.R.San.I. Leeds and Glasgow: E. J. Arnold and Son, Limited. 1908. Price 9*d.* net.—Miss Alice Ravenhill has written an interesting little book which has arisen out of the desire to draw the attention of those whose time does not permit them to study more detailed works on the subject to the significance of childhood. The characteristics and requirements of childhood are well and clearly set down, the educational needs of the children are considered in a temperate manner, and the educational needs of the school child are well catered for. There are shoals of publications purporting to cover this ground—either this only or this and a great deal more. Of some of these, particularly the more ambitious, we have had occasionally to say uncomplimentary things, but here it is our pleasant duty to be laudatory. Miss Ravenhill has set down clearly the salient characteristics of childhood and has indicated the chief requirements which the child ought to expect from those in charge.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by Professor WILLIAM OSLER, Dr. J. ROSE BRADFORD, Dr. A. E. GARROD, Dr. R. HUTCHISON, Dr. H. D. ROLLESTON, and Dr. W. HALE WHITE. Vol. II., No. 5. October, 1908. Oxford: At the Clarendon Press. Subscription price 25*s.* per annum, single numbers 8*s.* 6*d.* each.—The contents of this number are: 1. Extensive Atheroma and Dilatation of the Pulmonary Arteries without marked valvular lesions as a not very rare cause of fatal cardiac disease in Bengal, by Major Leonard Rogers, I.M.S., with four plates. This paper is a study of ten cases, one of which was correctly diagnosed during life, being the first in which this has been achieved. Major Rogers states that this condition of extensive atheroma of the pulmonary arteries with no marked disease of the systemic vessels and without any valvular affection occurs in Bengal and produces great hypertrophy and dilatation of the right cavities of the heart. It causes palpitation, dyspnœa, and dropsy, from tricuspid regurgitation, and in some cases terminates in hydropericardium to which the fatal result may be due. The cases nearly always occur between the ages of 20 and 40 years and they are almost certainly of syphilitic origin. 2. A paper on a case of Complete Heart-Block, by Dr. A. M. Gossage. The patient was a woman, aged 61 years, with complete heart block, the auricles and ventricles beating quite independently of one another. The case was associated with attacks of giddiness and convulsion of Stokes-Adams type. 3. A paper on Rheumatic Myocarditis, by Dr. Carey P. Coombs, in which it is shown that hypertrophy of both ventricles may occur without obvious mechanical cause and that dilatation is constant. Various histological lesions are described and these are of so special a kind as to support the conception of a specific rheumatic infection. 4. A paper on Mongolism and its Pathology, by Dr. W. Bertram Hill. This is a careful analysis of eight cases and affords an interesting study of the condition. The clinical features are discussed in detail and the pathological results obtained in two necropsies are described and compared with those found in other recorded cases. 5. A paper on the Medical Aspects of Pyelitis in Pregnancy, by Dr. E. Ward. The name of encyopyelitis is proposed for this condition which is stated to be more common than is generally supposed. It is due to infection of the renal pelvis with organisms, usually the bacillus coli communis. The prognosis is worse than has hitherto been recognised. 6. A Critical Review of Polycythæmia, Erythrocytosis and Erythæmia, by Dr. F. Parkes Weber. The extensive literature of these interesting conditions is reviewed and abstracted. A very long list of references is appended and the article should be of considerable value for purposes of reference.

New Inventions.

A SPHENOIDAL CHISEL.



OCCASIONALLY it is desired to open the sphenoidal sinus on account of annoying symptoms arising from an accumulation of pus within this sinus. The chisel described below is recommended by the author as an aid to performing this operation. The instrument consists of a round rod of steel ⅛ in. in diameter and of a total length of 6 in., which includes a terminal chisel ⅛ in. thick, ¼ in. broad, and ⅜ in. long, with a central cutting edge. The chisel proper is rectangular in section. A screw thread is cut on the first four inches of the proximal end of the rod. Upon this thread is fitted a threaded collar of blue steel ¼ in. in length which can be easily manipulated with the fingers. This collar is so adjusted that its terminal extremity occupies a position on the rod which corresponds with the external skin on the septum, when the cutting edge of the chisel is carefully placed against the anterior wall of the sphenoidal sinus. When the surgeon has adjusted the chisel and while he holds it in proper position an assistant will tap gently the proximal end of the rod with a lead mallet until the proximal end of the collar corresponds with the external skin of the septum. The rule for placing this chisel correctly is to hold the blade of the chisel vertically, to rest the rod on the floor of the nostril, and to pass it inwards in contact with the lower margin of the superior turbinated bone, in which case the chisel will enter the sphenoidal sinus without fail when it is driven down to the proper distance. As a result of this manipulation a hole is made parallel with the septum ¼ in deep, ¼ in. broad, and ⅛ in. thick into the sphenoidal sinus. With the use of methods. The serum diagnosis has the advantage of greater facility and rapidity; one does not need the constant presence of the patient, a few drops of fluid suffice, and one can easily carry this little quantity of fluid for examination. 2. Negative reaction only constitutes a presumption against the diagnosis of tuberculosis. One must in this case repeat the test. 3. The comparison of the agglutinating power of the blood with that of pleural fluid would give interesting results. One can apply the same conclusions to the diagnosis of other pathological fluids (especially ascites and hydrarthrosis) except the cerebro-spinal, which is never agglutinative.

V.—*Serum Prognosis.*

The general idea of serum prognosis in disease and the signification of the agglutinating reaction in the evolution of the infectious maladies was proposed by us for the first time in 1896-97 *àpropos* of typhoid fever. We have demonstrated that the degree of the agglutinating power of the blood is the more powerful if the infection is less grave and the resistance of the subject is greater. This is probably applicable to all infectious diseases running a typical course. For tuberculosis the question is more complicated on account of the variability of the forms and the duration of the illness. But it would be as important as it is difficult to establish the prognosis of the illness by the varying agglutinating power in tuberculous patients. Since this date we have said[3] with Professor Arloing: "The agglutinating power seems to be inverse to the gravity of the infection"; and in 1900 we arrived at the same conclusions by animals rendered artificially tuberculous.

The principal arguments on which serum prognosis is based are the following:—

1. *General statistics.*—In tuberculous subjects in whom the serum is not agglutinative from 10 to 15 per cent. are nearly all very seriously ill. The subjects who have advanced consumption, miliary tuberculosis, caseous pneumonia, and meningitis have nearly all a negative serum reaction.

2. *Experiments in animals rendered artificially tuberculous.*—The development of the agglutinating power is the more marked when the tuberculosis is less virulent and the animal more resistant and conversely.

3. *Variations of intensity in the agglutinating power of the tuberculous.*—These variations appear to be dependent on the gravity and progress of the disease. Very marked reactions are found especially in subjects in whom the tuberculosis is slight or becoming quiescent (local tuberculosis of the viscera, fibroid tuberculosis of the lungs, primitive pleural tuberculosis of Landouzy, &c.). Reciprocally slight agglutinations are found especially in patients more seriously ill.

4. *Variations of the agglutinating power in the same subject.*—If one watches for a long period of time a particular tuberculous subject one frequently sees the agglutinating power of his serum rise if the patient improves, and on the contrary fall if the illness becomes worse, and at times even disappears completely. Here are some examples of these two variations:—

(*a*) *Tuberculous pleurisy with a favourable serum prognosis.*—G——, aged 18 years, suffering from tuberculous pleurisy, with effusion, without any other complications; prognosis considered favourable.

Agglutinating Power of Pleuritic Fluid.

Ninth day	+ 5
Fourteenth day	+10
Twenty-first day	+15

(*b*) *Tuberculosis with an unfavourable serum prognosis.*—M., aged 28 years; pregnancy; double pleurisy with fever, secondary phthisis; death in 96 days.

Agglutinating Power.

	Of blood.	Of pleuritic fluid.
Twentieth day	+10	... ... +5
Fiftieth day	+ 5	 0
Eightieth day	0	 0
Ninty-fifth	0	 0

In the first case one sees the agglutinating power increasing until recovery ensues, and in the second fall until death ensues.

5. *Mortality of tuberculous pleurisy considered in relation to the agglutinating power of the pleuritic fluid.*—We have studied more than 120 cases of tuberculous pleurisy and kept in touch with the patients during eight years. If one compares the mortality of patients in whom the pleuritic fluids were agglutinous with that of patients of whom the fluid was not agglutinous one arrives at the following conclusions: 75 per cent. of cures in cases of positive reaction; 73 per cent. of deaths in cases of negative reaction.

Conclusions.

1. *Value of the method.*—The agglutinating power of serous effusions in tuberculous patients must be considered as a very important point in diagnosis and prognosis. It must be studied in all its variations, according to the ages of the patients, localisation, form and degree of lesions, and also in relation to the subsequent reactions which may be obtained.

2. *Necessary precautions.*—In order to make the investigation valuable sero-reaction must be looked for under the most exact conditions as regards the choice of the culture and the general technique of the reaction.

3. *Limitations of the method.*—Given that the agglutinating power of normal serum varies according to age and also to the animal species investigated, serum reaction has a diagnostic value only when the degree of agglutination is higher than the ordinary degree of agglutinating power of the serum of normal individuals of the same age and belonging to the same species.

4. *Serum diagnosis.*—For practical purposes serum reaction must be applied with great clinical discrimination; its results must be compared with the other symptoms and not interpreted blindly. It would not be wise to regard a patient as clinically tuberculous for the sole reason that his serum agglutinates Koch's bacilli. The reaction can have no diagnostic value unless there are other reasons justifying the suspicion of tuberculosis. *In such cases, however, a positive serum reaction has a great value:* negative reaction is of less value. Diagnostically, serum reaction can be considered from different points of view:—

(*a*) *General reaction* (with blood serum).—It does not give information as regards the location of the lesions and indicates only that the system has been or is actually under the influence of tuberculosis. It will be the clinician's task to interpret this information and to derive from it conclusions concerning the localisation of lesions. The serum diagnosis will be of especial use in children, in old people, and also in adults suffering from chronic or latent forms of tuberculosis. Results pointing to the frequency of latent tuberculosis in adults who clinically do not appear tuberculous are almost the same with serum reaction as with tuberculin test (either subcutaneously or in the eye).

(*b*) *Local serum reaction.*—It consists in testing the agglutinating power of serous effusions and indicates the site of the lesions. It is particularly useful for the diagnosis of tuberculous pleurisy, and its results are in accordance with those given by inoculations or cyto-diagnosis.

5. *Nature and prognostic value of serum reaction in tuberculous patients—serum prognosis.*—As is the case in many other diseases the agglutinating power of blood serum and other organic liquids in tuberculosis is proportional to the resisting power of the patients; furthermore, it is in an inverse ratio with the virulence of infection. Serum reaction is frequently absent in very serious or very advanced cases of tuberculosis. It reaches its maximum height in cases which are in the process of healing. It can diminish or disappear sometimes before death; it can, on the contrary, increase when there is a tendency towards healing or towards arrest. It seems to be an index of the protective reaction of the system.

6. *The study of serum reaction and its variation has a real value in prognosis.*—In tuberculous pleurisy with effusion an increasing agglutinating power carries with it a good prognosis, but failing any reaction one must be prepared sooner or later for a fatal result.

Lyons.

HOSPITAL SUNDAY IN PLYMOUTH.—As a result of the recent Hospital Sunday collections at Plymouth the sum of £739 has been handed to the treasurer of the South Devon and East Cornwall Hospital.

[3] Congress on Tuberculosis in Berlin.

THE LANCET.

LONDON: SATURDAY, DECEMBER 12, 1908.

The Treatment of Incipient Insanity.

IN an address recently delivered before the Forfarshire Medical Association Dr. A. R. Urquhart made certain suggestions for bridging or avoiding the gap which is so often apparent between an insane patient's home and the asylum. He referred to the work that had been done in Glasgow in this connexion. There the fact that a person is mentally afflicted is reported to the medical man who visits and deals with him in a systematic manner. It is plain that it is not necessary to remove every person so afflicted from his home, even though he be certifiably insane, and if it be desirable to remove him from his home it is by no means invariably desirable to place him in an asylum, and for such cases provision is made in the Eastern District Hospital where the patients are placed under observation, care, and treatment until recovery takes place or removal to an asylum becomes imperative. Dr. Urquhart suggested that at Dundee, where he was delivering his address, two small wards with 30 beds would be sufficient. The name of such wards was a matter of considerable importance and such terms as "mad wards" or "asylum wards" could not be permitted. Dr. Urquhart laid much stress on the necessity of regarding insanity as an affair of medicine and he urged his audience not to be diverted from the path of correct treatment or to be obstructed therein by the law. The law imposed upon them a primary consideration of conduct, while medicine imposed upon them the recognition and investigation of disease and the endeavour to remedy or to assuage its ravages. Their plain duty was the recovery of the curable, the care of the incurable, and the after-care of the convalescent. Professor MacEwan also addressed the meeting and pointing out that it was one of the most noticeable features of modern medicine that it endeavoured to deal with cases of disease from their earliest beginnings, so as to make some impressions before the patients became incurable, stated that in insanity the patients did not get any treatment until they had become insane, that is, until they could be certified for detention in an asylum. He argued that cases of incipient insanity should be treated in a general hospital and his ideal would be that there should be a department in the hospital for nervous diseases and that the term insanity should disappear.

In these columns we have from time to time advocated similar schemes and in the report of the Commission upon the Feeble-minded provision to meet such requirements is urged upon the nation. There is without doubt a large class of unfortunate mental patients for whom the profession, the charitable public, and the State have failed to make sufficient provision. Too often the medical man, able to recognise insanity when it has become certifiable, fails, from lack of special knowledge, to regard as serious certain symptoms which are, in fact, the prelude to mental breakdown or, recognising them, is at his wits' end to know what to do or where to place his patients before the moment arrives when certification is no longer to be avoided. So also have the charitable public failed to recognise that the insane person is a sick person and that his illness is one that can often be successfully treated if treatment is commenced early and that the longer treatment is postponed the less good can it effect. It is as if the public should think that a patient cannot have a pulmonary tuberculosis until he has had a hæmoptysis. To the alienist the most heartrending experience is to note the neglect of treatment at that stage of the disease when complete restoration to health is still possible and the slow declension of the mental faculties which he knows must eventuate in such an outbreak that even the public must recognise that disease is present. That the State has to a certain extent been responsible for this unfortunate state of affairs is obvious. In its desire to bring every mental patient under its cognisance it has created a dislike for the publicity of certification, which only induces the friends of patients to take them to the alienist when certification has become absolutely necessary; it has erected a barrier between the medical man and his mental patient which can only be broken down by certification or by the ignoring of the law on the part of the medical man, and it has induced a general impression that an asylum is a species of prison to which persons must go against their will, in which they are "confined," and from which they sometimes "escape," and to which, if "caught," they can be taken back by the constable.

It is pleasing to reflect that this heavy wastage of the mentally sick to the ranks of the certified insane, which is to a large and as we believe to a hitherto unsuspected extent preventable, is to be combated in London by the beneficence of a distinguished alienist, Dr. H. Maudsley. We trust that his scheme may before long be realised. We cannot, however, but regret that the projected hospital for mental diseases cannot be coupled, to some extent, with a hospital for nervous diseases. One of our hospitals for diseases of the nervous system is shortly to be rebuilt on a large scale and is possibly to be provided with accommodation for so-called "borderland" cases and this would seem to afford an opportunity of considering the desirability and the feasibility of establishing such a relationship. That in the out-patient departments of our hospitals for nervous diseases many cases are to be met with which are, in fact, mental cases is a well-recognised fact, and it is in those departments that is most acutely felt the problem of what to do for the accommodation of the unfortunate sufferers.

◆

The Progress of the Housing and Town Planning Bill.

IN spite of, or it may be because of, the small attendance at some of the meetings of the Standing Committee of the House of Commons which has been considering the Housing and Town Planning Bill, the labours of the Committee are now completed. Clause 13, which amends the greater pity that its quality must remain *a matter of trust* and not of demonstration. Absolute security based upon strict evidence cannot be obtained day by day for each day's supply. There is no simple test to be applied on the spot like the test which we apply to a coin. Our position is one of uncertainty: *Caveat emptor.*

In conclusion, it would perhaps not be far wrong to say of the present milk-supply that at its best it is still precarious, that in its lower grades it needs reform, and that *in regard to the infants* of the poor it is a scandal and a scourge.

The Personal Factor in Digestion and the Individual Quality in the Milk.

We cannot overlook the fact that there are unusual subjects and unusual conditions not suited by ordinary supplies, besides the so-called "milk idiosyncrasies" where even mother's milk may not be tolerated. As regards cow's milk, incompatibility is the exception. The majority of cows yield digestible milk and the great majority of infants put up with the milk supplied to them. Absolute idiosyncrasy against all milk of any kind whatsoever is rare. But the genuineness of this absolute exclusiveness has perhaps not had its full test in the past for want of a sufficient assortment of milks.

Acquired intolerance, induced by gastro-enteritis or some other accident of health, is fortunately temporary and not intractable. The beginning of some of these gastro-intestinal catarrhs may be an insidious, ingravescent dyspepsia from long-continued alimentary disappointment in susceptible stomachs. The larger group illustrating the personal factor is that in which an idiosyncrasy exists for some milks only. For some of these infants vomiting is the safeguard against the risk of indigestion. But others, deficient in selective instinct, do not protect themselves in this way and incur the resulting apepsia and athrepsia. Some special milk has to be found which may chance to suit and to be properly digested, and if found the supply had better be continued. For all these cases a wider range of choice in milk would be a boon. Infants for whom bottle milk has to be provided may therefore be arranged into three groups: Group 1, the normal infants; Group 2, the normal infants accidentally turned into milk dyspeptics; and Group 3, the abnormal infants, with varying degrees of idiosyncrasy—a growing class in our generation.

The requirements special to the three groups, and percentage milk.—It is in the management of the temporary difficulties of Group 2 and of those permanently belonging to Group 3 that Rotch's system is most helpful. It goes beyond the principle "for each infant its own milk," in undertaking to supply "for each infant's mood its own milk." For the present we cannot work it on the vast scale required for the masses. As a fact it is most needed by a relatively small number; and it is superfluous to make provision for the mass just on the narrow lines suited for the minority. Percentage feeding is required every day for the sick stomachs of Group 2; and in its absence it taxes the highest skill, and too often baffles the mother, to find a life-sustaining substitute. This may perhaps be more readily found in the near future. At any rate our policy is clearly that of *prevention* by providing for Group 1 the good, health-preserving milk-supply which has been wanting. If only given a fair chance in this the vast majority of infants will cause little trouble.

The Infant as a "Strong Feeder."

Non-dyspeptic adults, with little thought for longevity, are hardened sinners against the law of percentage feeding. They are "strong feeders"—indifferent to the dead weight which exercises the vigour of their peristalsis. Strong feeders, too, are their breed. The ordinary infant thrives on the excess of his intestinal fulness and function and qualifies from the cradle for a "big eater" through overflowing supplies from the cow. The frugality of percentage feeding might correct that bias. But the objection might be whispered that it is an "unwise concession." It has been alleged that we have already sacrificed the hardness of our teeth to the softness of our food. Is it to the advantage of the race that we interfere with the primitive roughness of these intestinal athletics? We can afford to waive that discussion, as the urgently needed remedy is not at present obtainable from that quarter. What we do want is *an absolutely sound and absolutely reliable constant supply of best quality milk for infants.* The easy fulfilment of this requirement is perhaps in our hands this day.

[Dr. Ewart here exhibited to his audience samples of the stored milk supplied to him by the Vacca Milk Company, Limited, of Amsterdam, to which he had given an extensive trial at the instance of Mr. A. F. Bilderbeck Gomess. Dr. Ewart instanced a bacteriological report made by Dr. Klein to the effect that the milk had been effectively sterilised without boiling and retained in a sterile condition without the use of preservatives, while he quoted from the analytical reports of THE LANCET[3] as emphasising the fact that no "boiled" flavour was present. He added the results of his clinical inquiry to show that the milk, which has been used for export to the tropics rather than for the feeding of infants, might have a great future in the latter direction as it is digestible, produces no scorbutic symptoms, and children thrive upon it.]

A CASE OF NEURASTHENIA COMPLICATED WITH (?) "VASO-VAGAL ATTACKS."

BY MILDRED M. BURGESS, M.D. LOND.

IN THE LANCET of June 8th, 1907, a lecture by Sir William Gowers is published on the subject of "Vagal and Vaso-Vagal Attacks." The patient, whose condition is described below, suffered from "attacks" which apparently come under the same category.

History of the case.—The patient was a woman, aged 39 years. Her father and one sister died from morbus cordis, the former from aortic disease and the latter from "enlarged heart and dropsy." Before the present illness began she had lived an exceedingly active, energetic, and vigorous life. She was brought up in the country and went in for sports of all kind. At about the age of 23 years she trained as a nurse at a London hospital and subsequently did district nursing. Although full of energy she was never very robust and had been told that she had a "weak heart." Four years ago she went to South Africa and for six months was sister at a miners' hospital. She worked at very high pressure as she was single-handed. While she was there an epidemic of typhoid fever occurred, during which time she took day and night duty continuously for a month, getting only snatches of sleep in a deck chair. After leaving the hospital she went up to East Africa and camped out there for seven months. She thought that she had "a touch of the sun" during this period. From that time until she came under treatment in March last she never felt well. Two years ago she returned home and has since done occasional nursing, but not without much mental and bodily fatigue.

General condition.—The object of this article is to describe the definite "vaso-vagal attacks," but apart from these the patient also showed typical neurasthenic symptoms. She was always more or less tired, was very irritable at times, had lost all power of concentration, and occasionally was melancholic. She was thin and sallow, had no appetite, and was very constipated. There were tremor and twitching of the muscles of the hands and the tongue was tremulous. She complained that at times she felt very "dished," but this was the only indication she gave, in describing her symptoms, that she was suffering from definite "attacks." The nature of these was only discovered when the patient was under close observation. The physical examination was interesting as showing absolutely nothing organically wrong in any part of the body. The heart was not enlarged and the only irregularity was an occasional systolic murmur at the apex. The action of the heart was feeble, at times irregular; the sounds at the base were hardly heard in a recumbent position. The rate of the heart beats was inordinately quickened on moving from a recumbent to an upright position. The pulse ordinarily was slow, ranging between 60 and 70. The temperature was nearly always subnormal, ranging from 96·8° to 98·4° F., the latter being reached only six times in three weeks.

Description of "vaso-vagal attacks."—The attacks came on quite suddenly with a sense of extreme fatigue, amounting almost to loss of power. The patient usually turned to one side and lay quite flaccid and motionless. The extremities employment of the unqualified assistant ceased, the defendant found himself unable to pass his final examination and apparently took to practising without a qualification. In May of the present year it became necessary that a batch of recruits destined for the Spennymoor detachment of the 6th Battalion of the Durham Light Infantry should be medically examined before enrolment, and the colour-sergeant of the company called in Ross to make the examinations under the impression that he was a registered medical practitioner. He made the examinations and signed necessary certificates over the words "medical officer" printed on the official form, receiving 17*s.* as remuneration for doing so. According to the evidence of the colour-sergeant the defendant had acted on previous occasions in a similar manner but had not received fees for doing so and his certificates had been accepted without question; on the recent occasion he had signed the receipt for the 17*s.*, adding the word "surgeon" to his signature, and this was charged as a second offence. The magistrates who heard the case practically treated the matter as one breach of the law, ordering the defendant to pay the fees of the court, amounting to 5*s.* 6*d.* on the first charge and a fine of £3 inclusive of costs on the second. He appears to have been dealt with adequately, as no doubt he will not repeat his offence and as the carelessness of the military authorities in employing him laid him open to temptation.

---

[3] THE LANCET, March 8th, 1902, p. 675.

The official examination of recruits for military service is, however, one of importance to the State and an unqualified person pretending to perform it necessarily deprives of an emolument a medical practitioner who has not failed to qualify himself as such. A case of this kind, however, even more than those of the more ordinary class to which reference has been made, exposes to criticism the attitude of the law and of the public which acquiesces in it towards the practice or pretended practice of medicine by the unqualified. A man situated as the defendant was may be fined for signing his name on an official form after examining a recruit for the Territorial Army. If the same recruit chooses to consult in civil life an absolutely ignorant and illiterate quack, whose flamboyant advertisement in the pages of a local newspaper or on a hoarding has attracted his notice, the law, regarding him as an independent agent selecting his own medical adviser, affords him no protection whatever. The quack knows the law and as a rule manages to steer clear of the one risk which it places in his course. He knows, that is to say, that so long as he says and does nothing which can be construed as the use of a title implying registration as a medical practitioner, he can fleece his victim and endanger his health or his life with impunity. Members of the medical profession in a spirit of thankfulness for small mercies, perhaps ought to consider it a matter for self-congratulation that the public allows them some measure of protection against the competition of unscrupulous and fraudulent pretenders, but they may well marvel that the same public should so contentedly fail to protect itself, and in particular that it should leave the humbler and less educated portion of the community to the tender mercies of unscrupulous rogues. There are charlatans, no doubt, who make their living out of the credulity of those who ought to know better than to trust them but they are few in number and harmless in the results which they bring about in comparison with those who reap their harvest among the working classses. Such a state of affairs is inconsistent with the high honours accorded by the State to men distinguished in the practice of medicine and surgery, and it is to be hoped that the anomaly may be corrected soon.

The General Medical Council is proving itself alive to the importance of the matter, as was shown by the report unqualified practice prevention committee, an accou which we published in THE LANCET last week. The contained full information as to the prevention of un fied practice in other countries, and as a result of its ado the General Medical Council has signified to the Council that in this country persons requiring medica are not sufficiently protected by law from quacks and asked for the appointment of a Royal Commission to inq into the evil effects of unqualified practice.

Annotations.

"Ne quid nimis."

A DEPARTMENTAL COMMITTEE ON THE MIDWIVES ACT.

A Departmental Committee has been appointed by t Lord President of the *Privy Council* to consider the workin of the Midwives Act, and in particular with reference to th supply of midwives and the cost of training, the remunera tion of medical men summoned on the advice of midwive under the rules in pursuance of the Act, and the delegatio of their powers by county councils under the Act. Th chairman of the committee is Mr. Almeric W. FitzRoy, clerk of the Council, and the members are: Mrs. Charles Hobhouse, Mr. J. S. Davy, C.B., assistant secretary, Local Government Board; Dr. A. H. Downes, medical inspector for Poor-law purposes, Local Government Board; Dr. F. H. Champneys, chairman of the Central Midwives Board; and Mr. John Pedder, a principal clerk in the Home Office. Mr. H. J. Stanley, private secretary to the Lord President, and Mr. F. J. Welch, staff clerk in the Local Government Board, will act as joint secretaries. We are heartily glad to learn that the working of this Act is to be made the subject of official inquiry. It is an open secret that the Act has so far not given satisfaction, and this must have been gleaned from our own columns. The difficulties of securing a uniform supply of midwives throughout the country are very great, the remuneration of medical men summoned under the Act to the assistance of midwives has not been arranged properly, and the number of unworthy women who have secured a position on the Midwives Register is alarmingly great. This is shown, for example, by an account of the last meeting of the Central Midwives Board (p. 1787). But while we welcome a Departmental Committee to suggest remedies in these circumstances we do not consider that the medical constitution of the committee is very fortunate. Dr. Downes is an admirable and experienced official of the Local Government Board, and Dr. Champneys is the painstaking chairman of the Central Midwives Board, but who represents general medical interests? Who on this Committee really understands what they are? Some well-known general practitioner or one of the Direct Representatives of the medical profession on the General Medical Council should be invited to strengthen the deliberations.

to some unusual exertion, but they often occurred 24, 36, and 48 hours subsequently. As she recovered, however, the attacks followed more closely after the exertion. This was specially well marked in the last attack which occurred at the end of July, 1907. She had been free from them since June 8th. One night she slept badly, ate very little breakfast, and then went out and pushed her bicycle up a very steep hill. Feeling tired, she went into a cottage to rest and had "an attack." From this it seems possible that the result was due to the exhaustion of some stimulating centre rather than irritation of an inhibitory one. But whatever the cause, the phenomena were those of a slowed, feeble pulse and withdrawal of blood from the surface of the body, so that probably any theory that satisfactorily explains the much-debated question of surgical shock would also apply to this case.

Comparing this case with those described by Sir William Gowers it is interesting to note: 1. Absence of any kind of pain, tetanoid spasm, rigor, tingling, or anything resembling epilepsy. 2. There was no impairment of consciousness. 3. The presence of the sense of impending death. 4. The sudden sense of physical fatigue at onset. Case 2 in his series most closely resembles this patient.

Brixton Hill, S.W.

A CASE OF CEREBELLAR ABSCESS FOLLOWING MIDDLE-EAR SUPPURATION; OPERATION; DEATH.

BY GEORGE N. BIGGS, M.B., B.S. DURH.,

ASSISTANT SURGEON TO THE EAR, NOSE, AND THROAT DEPARTMENT, SEAMEN'S HOSPITAL ("DREADNOUGHT"), GREENWICH; REGISTRAR TO THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.

ON Sept. 17th a man, aged 35 years, presented himself at the Seamen's Hospital complaining of vertigo of 14 days' duration; at the onset it had been slight but for the last two or three days very severe, and there was a marked tendency to fall to the right side. Slight nystagmus was present, the movements being equal in both directions. The pupils were equal and reacted to light and accommodation, and there was no paralysis of any of the extra-ocular muscles. There was no facial paralysis and the patient had had no attacks of sickness or any headache, neither had there been any earache. There was no weakness of any of the other cranial nerves. The patient had had a discharge from his right ear for at least 20 years. No mastoid swelling or tenderness was present.

On examination of the right ear a large perforation involving almost all the membrana tympani was present and there was also a perforation in Shrapnell's membrane. Granulation tissue and cholesteatoma were present. There was no bulging of the posterior-superior meatal wall. The left ear was normal. The right grasp was found to be much weaker than the left and there was some incoördination on the right side in the rapid rotation of the hand. The knee-jerks were present and equal. The plantar reflex was flexor. The abdominal reflex was weak on the left side. The patient was dull and apathetic and answered with slow intonation but quite intelligently. The temperature was 98° F. and the pulse was 60.

I admitted the patient into the hospital and performed a complete radical mastoid operation. The antrum and middle ear were full of granulation tissue, cholesteatoma, and pus. The remains of the malleus only were found. The external semicircular canal was found to be carious but no fistula could be discovered entering the internal ear through the foramen ovale or foramen rotundum. As the condition of the external semicircular canal would quite have accounted for the vertigo and nystagmus, and as there were no very definite localising symptoms, I decided to wait for a few hours before exploring the brain in case any more localising symptoms might manifest themselves. At 10 P.M. the patient became very much more restless and was unconscious. The temperature was 101·2° and the pulse was 88. As he was obviously worse I decided to explore his cerebellum, as an abscess in that region would, next to the external semicircular canal, be the only likely lesion to account for his symptoms (i.e., vertigo, nystagmus, &c.).

An operation was performed, the patient being placed under chloroform. A curved incision downwards and backwards from the mastoid wound was made, the soft parts were turned down, and the skull was trephined at a point one and a half inches behind and from half to three-quarters of an inch below the external auditory meatus. On removing the bone the dura mater was seen to be very tense and bulged into the trephine opening. A needle with syringe attached was inserted forwards and inwards and pus was withdrawn. The dura mater was then incised and a tube inserted into the abscess with sinus forceps. There was some bleeding of a venous nature from the posterior part of the incision in the dura mater but this was stopped by plugging. The pus was very offensive. The wound was sutured, a dressing was applied, and the patient was sent back to bed. An examination of the patient's discs had shown the veins on both sides to be full, especially on the right side, but there were no signs of optic neuritis.

The patient's condition steadily improved and on the 21st, as there had been no discharge of pus from the abscess for three days, I left out the drainage-tube. His mental condition was quite normal again. On the 22nd he was very well but at 11 P.M. he suddenly vomited and gradually became drowsy and irritable and his pulse fell to 60, his temperature to 97°, and his respirations to 18 per minute. There was no change in the nervous system. On the morning of the 23rd I found that his condition was almost the same as when admitted, the only differences being that his left pupil was more dilated than the right and the reaction to light of the right pupil was rather sluggish. The pulse was 40, the temperature was 97°, and the respirations were 16. The left knee-jerk was perhaps slightly exaggerated.

Dr. R. E. Bickerton very kindly examined the patient's discs and reported that the veins on both sides were full but there were no definite signs of optic neuritis. As there was obviously some increased intracranial pressure, and on account of the condition of the pupils and left knee-jerk, I decided to explore the patient's temporo-sphenoidal lobe first and then again to explore the cerebellum. The patient was anæsthetised and a lumbar puncture was done by Mr. G. Williams. The fluid drawn off was quite clear and escaped gradually, showing no signs of increased pressure. Examination of the fluid revealed nothing abnormal. Sufficient bone was then removed to allow of the temporo-sphenoidal lobe being explored with a syringe in every direction. No pus, however, could be found, but a quantity of blood-stained cerebro-spinal fluid was withdrawn. The cerebellum was also explored with negative results. The wounds were sutured and dressed in the ordinary way. The patient's condition steadily got worse and he died on the 25th at 10 A.M.

A *post-mortem* examination was made. Unfortunately the patient's relatives refused to allow anything more than an examination of the head. There was no sign of meningitis except a purely local reaction around the tube opening in the cerebellum. No abscess was present in the temporo-sphenoidal lobes and no second abscess was found in the cerebellum. The ventricles were very distended with cerebro-spinal fluid which was quite clear. There was a tube tract going through the cerebellum almost reaching the medulla, although the abscess had been fairly superficial. None of the sinuses were thrombosed.

Presumably death was due to increased tension in the ventricles owing to some obstruction which the limited nature of the *post-mortem* examination failed to reveal. Repeated lumbar puncture could not have relieved the condition as the fluid that came away was not under increased tension at all.

I deeply regret that the *post-mortem* examination was of such a limited nature as the case was one of very great interest. My thanks are due to Mr. Williams, the surgical registrar, for the very excellent notes of the case.

Harley-street, W.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The distribution of prizes and an address to the students at this hospital will take place in the out-patients' hall at the hospital on Friday, Dec. 18th, at 4 o'clock. Mr. John H. Morgan, consulting surgeon to the hospital, will give the awards and the address.

freely bombarded with the result that Dr. Westwater had hundreds of wounded non-combatants on his hands. He worked day and night to relieve them with no trained assistants, and the report of it so delighted the Japanese Marshal Oyama that he sent £200 for the Chinese hospital. The greatest sacrifice of all that medical missionary work has demanded of Dr. Westwater was the life of his wife and fellow-worker who died during the typhus epidemic of 1905. This truly heroic man, who has received decorations from the Czar of Russia, has won much honour for medicine in the East and we take a pride in making his exploits widely known in his profession. During the present year he has been studying at the Edinburgh hospitals but will shortly return to the Far East to continue his labours for the people of Liaoyang, who would seem to hold him in such devotion as was accorded by an older generation to his great compatriot "Chinese Gordon." We wish him many years of continued activity.

CONGENITAL DIAPHRAGMATIC HERNIA IN AN OLD MAN.

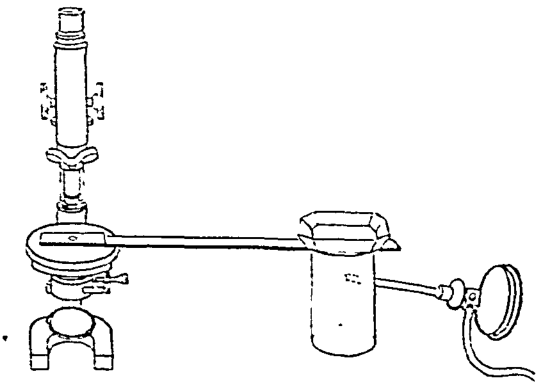
CONGENITAL diaphragmatic hernia in old age is rare. In the *Edinburgh Medical Journal* for November Mr. Alexander Don has reported the following case. A man, aged 61 years, sought advice for flatulence and pain after meals which often lasted for two hours. Occasionally he had also attacks of "sharp, choky pain" in which he could hardly get his breath. These lasted for a few hours and were relieved by "a lot of wind coming up and sometimes some mouthfuls of food." But, as a rule, food was not regurgitated, though he felt inclined to vomit and retched frequently. During the past 18 months the condition was so constant after meals that he was afraid to eat and lost about a stone in weight. Digestive troubles had existed for over 20 years. Recently there was some dysphagia, the food seeming to be arrested just before it entered the stomach and returning in mouthfuls. The organs were normal but the vessels were rather atheromatous. Abdominal examination revealed only slight pain on deep pressure in the epigastrium and double inguinal herniæ which were well supported by a truss. After some months' medical treatment without improvement Mr. Don began to suspect malignant disease of the stomach. On June 7th last exploratory laparotomy was performed. A vertical incision was made a little to the left of the middle line and the liver presented. The chloroform was well taken but when Mr. Don inserted his hand into the abdomen the breathing suddenly stopped. On removing his hand the patient again began to breathe. More chloroform was given but the same result followed whenever the hand was inserted into the abdomen. He was allowed to recover partially from the anæsthetic and the abdominal contents could then be examined, though with less ease than when the muscles were relaxed. On trying to examine the upper part of the abdomen the stomach slipped up under the hand, the breathing again stopped, and the patient became cyanosed. The stomach was seized and pulled into the wound and held there while the hand was passed behind it to examine the cardiac end. The hand could be passed through an opening about three inches in diameter in the diaphragm into the thoracic cavity. The respiratory trouble occurred whenever the hand was passed far through the opening. The difficulty experienced in vomiting or expelling wind during the attacks of pain was explained, for the part of the stomach that would then be herniated might press against the œsophagus. A couple of silk sutures were passed through the anterior wall of the stomach and fixed to the parietal peritoneum on either side of the incision. This was all that could be done owing to the rigidity of the abdominal muscles. The abdominal wound was sutured with through-and-through silk-worm gut sutures, two of which were fixed to the stomach. On August 21st he was still troubled with eructations but was free from the attacks of "sharp, choky pains." On Sept. 9th he could eat almost anything and had gained 6 pounds. Mr. Don has not been able to find a recorded case of diaphragmatic hernia at such an advanced age, though some examples appear to have been discovered post mortem. In this case the œsophageal opening in the diaphragm may have been large at birth but not so patent as to cause trouble, and retching and vomiting may have enlarged the opening so as to allow a portion of the stomach to pass through. A case of congenital defect in the diaphragm has been recorded which gave no trouble until the patient was in the fifth month of her first pregnancy. She was then seized with dyspnœa, vomiting, and symptoms of pneumothorax and died. Post mortem the stomach and intestines were found in the left pleural cavity. This case seems to show that increase of intra-abdominal pressure will enlarge the hernial opening. Naumann has recorded a case in which he operated for strangulated diaphragmatic hernia. The sigmoid flexure and omentum were herniated and could not be reduced. He thought that if he had opened the pleural cavity the negative pressure would have been overcome and he recommends this treatment in future cases. This view explains the behaviour of Mr. Don's patient under chloroform. As soon as air was allowed to enter the abdominal cavity the stomach was driven or aspirated into the thoracic cavity during the negative pressure accompanying inspiration and until it was held down it was impossible to make an examination. Potemski and others recommend opening the thorax, reducing the hernia from that side, and closing the diaphragmatic opening by plastic flaps. Gastropexy, which is an easier operation, does not seem to have been suggested previously. Mr. Don thinks that in his case a second operation may have to be done through the thorax if the symptoms recur.

ROYAL SOCIETY OF MEDICINE: THE ANNUAL DINNER.

THE annual dinner of the Royal Society of Medicine was held at the Hotel Cecil, Strand, on Dec. 4th, the President of the society, Sir W. S. Church, being in the chair. On the right of the chairman Lord Strathcona was seated and on his left Mr. A. Birrell, M.P. Amongst others present were Mrs. L. Garrett Anderson, M.D. (Mayoress of Aldeburgh), Sir R. Douglas Powell (President of the Royal College of Physicians of London), Mr. Henry Morris (President of the Royal College of Surgeons of England), Dr. G. Wilks (Master of the Society of Apothecaries), Surgeon-General Sir A. Keogh (Director-General of the Army Medical Service), Sir F. Bridge, Mr. Justice Darling, Major L. Darwin (President of the Royal Geographical Society), Surgeon-General A. M. Branfoot (President of the Medical Board of the India Office), Mr. Justice Walton (President of the Medico-Legal Society), Sir W. J. Collins (Vice-Chancellor of the University of London), Mr. C. B. Lockwood (President of the Medical Society), Mr. R. Marcus Gunn (President of the Ophthalmological Society), Inspector-General Sir H. M. Ellis, Sir E. R. Henry (the Commissioner of Police), Sir Lauder Brunton, Dr. F. Taylor, Mr. E.-Parker Young, Mr. J. Y. W. MacAlister (secretary), and Dr. J. Nachbar (assistant secretary). Mr. Birrell was loudly cheered on rising to propose the toast of "The Royal Society of Medicine." He said that he understood from the chairman that the society was the outcome of an amalgamation of a number of medical societies which were now termed sections of the society. These had now been welded together into the Royal Society of Medicine and they met that night to

A blood chamber is prepared as follows. A morsel of plasticine much smaller than a pea is rolled out with a glass slide until it is about one and a half inches long and as thick as the lead of a pencil, and then bent round in a spiral way and fixed in the middle of another clean glass slide, as shown in Fig. 2, forming a chamber A, with an exit E. A fairly large drop of fresh blood is obtained and allowed to fall into the chamber at A; a cover-slip is superimposed and pressed down carefully with another slide, so that as the clay flattens blood and air are driven out through the exit E, which must always remain patent, and a thin, even layer of blood fills the chamber and the exit passage; this is shown in Fig. 3.

FIG. 1.



A general view of the apparatus.

FIG. 2.

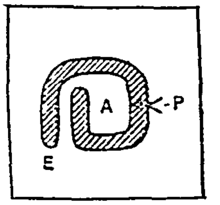


FIG. 3.

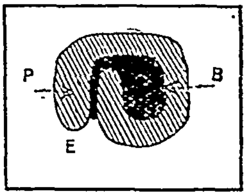

A, Chamber occupied by B, Blood. P, Ring of plasticine. E, Exit.

A little practice is necessary to perform this successfully, but unless it is wished to keep the leucocytes alive several hours, an air bubble in the chamber does no harm. The slide is now placed in the incubator at blood temperature, or simply in the bath of warm saline solution which is at a temperature of about 38° C., and it is left here 15 minutes. During this period the blood clots and the leucocytes escape, apparently by their own activity, and passing both upwards and downwards seek the glass surface of the slide and the cover-slip in hundreds, to which they adhere tenaciously. In order to get rid of the clot and serum the cover-slip is carefully removed and both cover-slip and slide are placed in the warm saline bath, which has been prepared ready; the remains of the clot and plasticine are removed with fine forceps or needles and both cover-slip and slide are washed gently by passing them to and fro under the saline solution; this process is continued until the free red corpuscles are all washed away, as seen by the disappearance of the reddish colour. If now the cover-slip or slide be held up to the light an even grey film can be seen with the naked eye, which consists entirely of leucocytes, adhering to the surface of the glass. Two preparations can now be made; one, by placing a clean cover-slip over the film on the slide, moistened with saline solution; the other by placing the cover-slip on which is a film of leucocytes on a clean slide, also allowing a little saline solution to interpose; in the former case the leucocytes are lying on the upper surface of the slide, in the latter case they are hanging from the lower surface of the cover-slip, and indeed a hanging drop preparation can be made from the cover-slip. On examining with a microscope either of these preparations the field is seen to be crowded with active leucocytes of every shape, and the appearance is not masked nor the movements hindered by the presence of red blood cells or fibrin.

If it is desired to bring in contact with these leucocytes any fluid, such as one containing a suspension of bacteria, and watch the result, it can be done by the hanging drop method, or better by placing the cover-slip on which is the film of leucocytes *face downwards on a plasticine chamber* similar to the one originally described, but which contains a drop of the fluid, such as a suspension of bacteria, and pressing it down to form another chamber in the way described for the original blood. In this way a clear view of what takes place is obtained and evaporation cannot occur to any detrimental degree if the exit is quite narrow. The leucocytes can be watched in conditions more approximating those of their natural habitat if the second chamber is made with a drop of serum obtained by centrifugalising the same blood as that from which they were originally obtained.

By this method living isolated leucocytes can be segregated directly from human blood and kept under observation in vitro, without further precautions, for about an hour.

Cambridge.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PURE MYXOMA OF THE LOWER JAW.

BY D. W. DANIELS, M.B., B.S. LOND., M.R.C.S. ENG.,

HOUSE SURGEON TO ST. MARY'S HOSPITAL, PADDINGTON, W.

THE patient, a woman, aged 27 years, first noticed a hard lump in the outer side of the gum of the lower jaw nine months ago. It gave her no pain. The tumour slowly grew and began to get painful. In October last it started to grow more rapidly.

On admission there was a swelling of about the size of a marble opposite the bicuspid teeth of the left lower jaw. The tumour was firm and hard all over. There was no fluctuation. No obvious swelling could be seen on the cheek.

An incision was made over the swelling between the gum and cheek. It was then found that the tumour readily shelled out entire, leaving a cavity in the bone, extending right through to its inner margin.

Microscopical examination showed the tumour to be a pure myxoma, unmixed with any other tissue, sarcomatous or otherwise.

I have to thank Mr. A. J. Pepper for permission to publish these notes.

St. Mary's Hospital, W.

RUPTURE OF THE LIGAMENTUM PATELLÆ.

BY DR. PARAVICINI.

SEEING from an annotation in your pages[1] and from a letter which appeared the following week that cases of rupture of the ligamentum patellæ have been seldom recorded, I venture to contribute the following notes. The case offers the special feature that no direct violence to the tendon itself took place, the hyperflexion of the knee and simultaneous contraction of the quadriceps having been the only possible causes.

The accident happened to myself some six years ago in the Swiss mountains. Running down a steep slope covered with a thin layer of snow I slipped and fell, my left gluteal region touching the left heel, my left leg being completely doubled. I felt a cracking and an acute pain and found myself unable to stretch the left leg by its own force. Through my trousers I noticed a gap below the patella which was drawn up by the quadriceps extensor. There was no external wound nor the slightest sign of a contusion. I was alone and only able to crawl slowly. After having called for help during two hours I grave alvine pollution exists Dr. Houston in his recent experiments was unable to detect the typhoid bacillus in 29,400 cubic centimetres of these three raw waters in his examination of 52 samples from each source. The total number of bacteria found on gelatin culture was 135,687,500. Of these colonies all but 7329 were more or less coloured and so were excluded from further observation. The colourless colonies, which might possibly have been typhoid bacilli, were sub-cultured by six differential methods and by one or another all were proved not to be Eberth's organism. In 6024 the exclusion was made by Proskauer and Capaldi's No. 2 medium (with inner tube), in one case by their No. 1 modified medium, in 49 by "L.S.D.S. Rebipelagar" medium (with inner tube), and in 1255 by the various gelatin sugar media, to the differential value of which method Dr. Houston bears strong witness. Full details of the experiments are included in an addendum to the report. It is a matter of general knowledge that the isolation of typhoid bacilli from water is a task of great difficulty but Dr. Houston is satisfied as to the negative value of his findings and indeed comments on the comparative ease with which the suspected typhoid bacilli were excluded by simple tests. At the same time, in dealing with waters containing so many colon bacilli we are only justified in concluding that there was no pronounced typhoid epidemic occurring in the communities discharging their sewage into the rivers in question at the time when the samples were taken. Dr. Houston admits that "it would be presumptuous to infer from these observations that the typhoid bacillus is never present in the raw river waters, or to conclude that any relaxation in the processes of purifying the raw waters, by storage and filtration, before delivery to the consumer is justifiable." He proposes to continue the experiments with a much larger volume of raw water, using a special centrifugal apparatus to separate the organisms. The monthly report on the condition of the metropolitan water-supply for September has also been issued in a prompter manner than have many of its predecessors. The Thames was in good condition throughout the month. Bacillus coli was found in 100 cubic centimetre samples of filtered Thames, Lea, and New River water in the percentage proportions of 12·6, 13·7, and 8·4 respectively. The filtered waters (except the Clapton and New River supplies) showed a slight deterioration of quality as judged by the albuminoid nitrogen and oxygen absorbed from permanganate tests. The results were, however, up to the 1907 standard.

---

[1] THE LANCET, Sept. 12th, p. 825.

THE "ILLNESSES" OF THE ELEMENTS.

THERE are abundant chemical phenomena indicating that stability can only be a relative term, and the truth is probably that no element is absolutely stable. The discovery of radium has introduced the doctrine of degradation, but whether that be definitely established or not, and radio-energy apart, spontaneous change would appear to be as true of inorganic materials as it is of organised entities. Yellow phosphorus gradually assumes a new complexion if left to the agencies of time, finishing a beautiful dark red. Is this a step in its retrograde movement towards becoming, that is, an element of a lower order? Why, again, does tin crumble to a grey powder if exposed for a long time to the cold. The change is known as "tin plague"; the smooth surface of the metal after an exposure to 16°–45° C. for two years becomes brittle and crystalline. "Tin plague" is even "infectious," for on inoculating other masses of smooth polished tin with small portions of the crystalline metal the "disease" spreads, the area affected increasing in diameter from three to five millimetres daily. Tinfoil succumbs to the infection in the same way and becomes crystalline and brittle right through. Why, again, does the railway line snap except that it is attacked by the same "crystallising disease"? It would even appear that certain metals have their "illnesses," as though their activities were interfered with by a toxic process which may be pushed in many cases to such an extent that the metal "dies." Platinum, for example, in its colloidal form, in which it is very remarkably active, is positively "poisoned" by prussic acid or corrosive sublimate, and its great energies cease to act: it is killed. The beautiful liquid lustrous metal mercury gets "sick," non-mobile, dull, and streaky the moment that it absorbs impurities. Under electrical stress glass gets "fatigued," as in the x ray tube. Silver "spits" just as it solidifies, having breathed in, so to speak, oxygen while it was in the liquid state. These incidents, and others which might be recalled, are almost startlingly human in their nature.

INFANTILE MORTALITY IN STAFFORDSHIRE.

THE recently issued quarterly return of the Registrar-General relating to the three months ending with September last again records exceptionally high rates of infantile mortality in many of the urban districts of Staffordshire, more especially in the Pottery districts. The deaths of infants under one year of age during last summer quarter were equal to 177 per 1000 registered births in Hanley, 178 in Oldbury, 208 in Longton, 242 in Tunstall, and 288 in Burslem. In the 76 largest English towns during these three months the mean rate of infantile mortality did not exceed 145 per 1000; and in view of the following low rates that prevailed in other industrial towns—79 in Portsmouth, 85 in Halifax, 90 in Norwich, and 95 in Northampton—the waste of infant life in the above-mentioned Staffordshire towns stands out in striking contrast and gives additional interest to the remarks of Dr. George Reid, the medical officer of health of Staffordshire, in his last annual report for 1907. He therein points out that the rate of infantile mortality during last year exceeded 170 per 1000 in five urban districts in Staffordshire, Longton, Bilston, Brierley Hill, Darlaston, and Tunstall. While it is satisfactory to find that the rate in each of these five towns in 1907 showed a considerable decline from the rates that prevailed in recent years, Dr. Reid expresses doubt as to what proportion, if any, of this decline may justifiably be attributed to improved hygienic conditions or increased maternal care, having regard to the unquestionably powerful influence of the relatively low summer and autumn temperature that prevailed during 1907. With regard to the rate of infantile mortality in Longton, from information collected by the local lady sanitary inspector, Dr. Reid reports that the rate of mortality among wholly breast-fed infants during the year did not exceed 111 per 1000, while it was 147 among those partly breast-fed, and was no less than 442 per 1000 among nearly 200 infants entirely fed on artificial food. Dr. Reid has long maintained that the industrial employment of married women is one of the most potent factors in the causation of infantile mortality. He shows in his recently issued report that in eight Staffordshire towns, containing under 6 per cent. of married or widowed women out-workers, the rate of infantile mortality last year did not exceed 143 per 1000, while in 13 towns in which the proportion of women so employed ranged between 6 and 12 per cent. the mean rate was 154, and in five other towns in which more than 12 per cent. of the married or widowed women are engaged in work away from home the deaths of infants aged under one year were equal to 188 per 1000 births. These figures appear to support the asserted intimate relation between the proportion of married women employed away from home and excessive rates of infantile mortality. Dr. Reid's report, moreover, suggests that the recent decline in the still excessive rates of infantile mortality among the urban population of Staffordshire may in part be resulted in no great improvement on the original condition. He related a case in which the ureters had been implanted into the sigmoid flexure, but the latter became kinked with fatal issue. The operation done in Mr. Rigby's case was much simpler than many other operations and the shock was less.

Dr. G. A. **SUTHERLAND** showed a boy with Enlargement of the Liver and Spleen in which a diagnosis was made of Cirrhosis of the Liver. Mercury had been given.—Dr. **CAUTLEY** suggested that the rapid way in which it had yielded to mercurials suggested that the cirrhosis might have a syphilitic origin. Another possibility was that the child had some peritonitis, possibly tuberculous. He hoped that Dr. Sutherland would keep the case under observation and report upon it later. True atrophic cirrhosis was rare in children.—Dr. E. I. **SPRIGGS** said an important point would be as to whether the liver was nodular. He had not been able to feel the nodules himself but Dr. Sutherland had had an opportunity of examining the boy under more favourable conditions. The enlargement of the liver was not great; neither was the spleen larger than was sometimes found in cases of tuberculous peritonitis. He asked whether the temperature had been raised in the course of the illness. He did not think it was a case of Banti's disease as anæmia was not pronounced and the enlargement of the spleen was only moderate—Dr. **SUTHERLAND** defended the diagnosis of atrophic cirrhosis. He did not think that rapid improvement under mercury in such a case was sufficient evidence of syphilis. He thought it very likely that there was some perihepatitis and that the mercury had benefited that. The onset was sudden, with pain and distension of the abdomen. There had been no pyrexia. A short time ago there had been less fluid in the abdomen than at present and he had been able to feel that the liver was nodular and could feel no tuberculous mass. Although Banti had first shown the connexion between splenic anæmia and hepatic cirrhosis he did not think that this entitled the combination of these conditions to be known by his name. He thought it very unfortunate that the term had come into such common use in this country as a disease.

Mr. **SYDNEY STEPHENSON** showed a case of Ptosis Adiposa (blepharochalasis) in a child, aged seven years, the condition in which the upper eyelid drops over the eyelash.—Dr. **SUTHERLAND** passed round a photograph of a similar case which he had shown some years ago at the Society for the Study of Disease in Children. He had recently seen a case in which no benefit had followed an operation, and this patient developed marked spasm of the occipito-frontalis and a corrugated forehead, due to her efforts to raise the upper lid.

Dr. **CARPENTER** showed three cases of Congenital Deformity, of the skull, of the fingers, and of congenital dislocation of the hip, with specimens.

Mr. **HUGH LETT** showed a case of Facial Paralysis in a child, aged five weeks.

Dr. **CARPENTER** showed a case of Pseudohypertrophic Paralysis in a boy.—Dr. **SPRIGGS** remarked on the great diminution of muscular tissue in both the pseudohypertrophic and atrophic cases of progressive muscular dystrophy. He had found that this was associated with a very great diminution in the kreatinin in the urine and this afforded valuable evidence that kreatinin was mainly derived from muscular tissue.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Pityriasis Rubra Pilaris.—Oral Sepsis.—Lantern Demonstration.

A MEETING of this society was held on Dec. 2nd, Dr. **JAMES RITCHIE**, the President, being in the chair.

Dr. **NORMAN WALKER** exhibited a girl, aged 11 years, suffering from Pityriasis Rubra Pilaris as a rare and interesting case. He called attention to its superficial resemblance to psoriasis and to its insidious onset; it had also been confounded with ichthyosis, the skin being specially dry and hard on the knees. It was attended by the development of small papules around the hairs, and these ran together to form large map-like areas—erythrodermic areas. One observer had noted a relation between this disease and tuberculosis, and the patient exhibited was suffering from apical phthisis. The prognosis was not good and the condition as a rule lasted many years. The condition of the legs had improved under the action of weak salicylic vaseline ointment and good food with cod-liver oil and tonics. There was no specific treatment. Doubtless this was the same disease as that which Hebra described as lichen ruber acuminatus, and he affirmed that it invariably ended fatally unless arsenic was administered in large doses. Kaposi also employed this drug hypodermically.

A discussion on Oral Sepsis was opened by Mr. **WILLIAM GUY** who spoke as follows: It is well to remember that the mouth during extra-uterine life is never sterile. We have always present the bacteria which constitute the indigenous flora of the mouth and are not necessarily pathogenic; we find from time to time pyogenic organisms, staphylococcus pyogenes aureus and albus and streptococcus pyogenes and those which are concerned in the production of caries and of disease of the pulp, the various forms of leptothrix and bacillus gangrenæ pulpæ, and finally those which obtain fortuitous entry, such as pneumococcus, tubercle bacillus, and many other pathogenic organisms. The mouth affords the most favourable conditions not only for the multiplication of fission fungi and the production of their specific toxins but also for the emigration of septic material to other organs and the absorption of toxins. While I am prepared to maintain the thesis that a condition of sepsis in the oral cavity is of itself a sufficient deviation from health to claim the attention of physicians, surgeons, and dentists, I feel that the interest of members will be more concerned with the condition as a certain, probable, or possible factor in the causation of disease or as an intercurrent malign factor in the progress of other diseases. In spite of all that has been said or written, and particularly by Dr. William Hunter, I question if oral sepsis as the cause of septic gastritis is as frequently recognised as it should be. Why for countless ages has the tongue alone been subjected to a careful scrutiny? Why in histories of medical cases is the condition of the mouth ignored or alluded to in vague terms; the importance of observing and reporting on the condition of the mouth *quâ* sepsis should be insisted on. The physician may enlist the services of the dentist in the treatment of his cases, and I wish that the physician would always indicate what he expects the dentist to do and he should explicitly state what he wishes done—as, for example, to put the mouth in a thoroughly healthy condition, remove roots, treat decayed teeth, &c. Such an instruction from the physician would tend to the maintenance of a high scientific standard of professional work amongst dentists, not to mention the satisfaction that they would feel in being asked to coöperate with the physician. On the surgeon I would urge the necessity of attention to the hygiene of the mouth previously to the performance of any operation involving that cavity or any part of the digestive tract. I pause here to invite your views on oral sepsis as one of the principal causes of appendicitis. Rhinologists are, I believe, agreed that in suppuration of the antrum of Highmore the route of infection is much more frequently nasal than dental, but I should like them to consider the possible frequent infection of the nose from the mouth. Aurists must have many opportunities of noting infection of the middle ear from the mouth. In the treatment of pulmonary tuberculosis the condition of the mouth and teeth deserves careful attention. I believe that in the course of all acute diseases, and especially of the exanthemata, the presence or absence of oral sepsis is often the determining factor in the death or recovery of the patient. I should like to hear of some accurate observations being made in this connexion in our fever hospitals, especially in regard to scarlet fever. There is now provision made for medical inspection of school children. Dental caries is the most prevalent of all diseases. What is the good of inspection without treatment, and how is that treatment to be paid for? In the vast majority of school children I believe it is wiser to extract carious milk teeth than to attempt to fill them; better a clean mouth than a dirty one. I even question whether any tooth that has become septic in a child should be retained. In cases of septic adenitis I think the physician should advise the removal of any septic teeth, and I further think that the dentist would be wise to carry out the direction without hesitation or demur. The alienist will tell us, I hope, that the hygiene of the mouth is an essential part of the hygiene of the mind. I recall two cases of empyema of the antrum which produced profound grave alvine pollution exists Dr. Houston in his recent experiments was unable to detect the typhoid bacillus in 29,400 cubic centimetres of these three raw waters in his examination of 52 samples from each source. The total number of bacteria found on gelatin culture was 135,687,500. Of these colonies all but 7329 were more or less coloured and so were excluded from further observation. The colourless colonies, which might possibly have been typhoid bacilli, were sub-cultured by six differential methods and by one or another all were proved not to be Eberth's organism. In 6024 the exclusion was made by Proskauer and Capaldi's No. 2 medium (with inner tube), in one case by their No. 1 modified medium, in 49 by "L.S.D.S. Rebipelagar" medium (with inner tube), and in 1255 by the various gelatin sugar media, to the differential value of which method Dr. Houston bears strong witness. Full details of the experiments are included in an addendum to the report. It is a matter of general knowledge that the isolation of typhoid bacilli from water is a task of great difficulty but Dr. Houston is satisfied as to the negative value of his findings and indeed comments on the comparative ease with which the suspected typhoid bacilli were excluded by simple tests. At the same time, in dealing with waters containing so many colon bacilli we are only justified in concluding that there was no pronounced typhoid epidemic occurring in the communities discharging their sewage into the rivers in question at the time when the samples were taken. Dr. Houston admits that "it would be presumptuous to infer from these observations that the typhoid bacillus is never present in the raw river waters, or to conclude that any relaxation in the processes of purifying the raw waters, by storage and filtration, before delivery to the consumer is justifiable." He proposes to continue the experiments with a much larger volume of raw water, using a special centrifugal apparatus to separate the organisms. The monthly report on the condition of the metropolitan water-supply for September has also been issued in a prompter manner than have many of its predecessors. The Thames was in good condition throughout the month. Bacillus coli was found in 100 cubic centimetre samples of filtered Thames, Lea, and New River water in the percentage proportions of 12·6, 13·7, and 8·4 respectively. The filtered waters (except the Clapton and New River supplies) showed a slight deterioration of quality as judged by the albuminoid nitrogen and oxygen absorbed from permanganate tests. The results were, however, up to the 1907 standard.

THE "ILLNESSES" OF THE ELEMENTS.

THERE are abundant chemical phenomena indicating that stability can only be a relative term, and the truth is probably that no element is absolutely stable. The discovery of radium has introduced the doctrine of degradation, but whether that be definitely established or not, and radio-energy apart, spontaneous change would appear to be as true of inorganic materials as it is of organised entities. Yellow phosphorus gradually assumes a new complexion if left to the agencies of time, finishing a beautiful dark red. Is this a step in its retrograde movement towards becoming, that is, an element of a lower order? Why, again, does tin crumble to a grey powder if exposed for a long time to the cold. The change is known as "tin plague"; the smooth surface of the metal after an exposure to 16°–45° C. for two years becomes brittle and crystalline. "Tin plague" is even "infectious," for on inoculating other masses of smooth polished tin with small portions of the crystalline metal the "disease" spreads, the area affected increasing in diameter from three to five millimetres daily. Tinfoil succumbs to the infection in the same way and becomes crystalline and brittle right through. Why, again, does the railway line snap except that it is attacked by the same "crystallising disease"? It would even appear that certain metals have their "illnesses," as though their activities were interfered with by a toxic process which may be pushed in many cases to such an extent that the metal "dies." Platinum, for example, in its colloidal form, in which it is very remarkably active, is positively "poisoned" by prussic acid or corrosive sublimate, and its great energies cease to act: it is killed. The beautiful liquid lustrous metal mercury gets "sick," non-mobile, dull, and streaky the moment that it absorbs impurities. Under electrical stress glass gets "fatigued," as in the x ray tube. Silver "spits" just as it solidifies, having breathed in, so to speak, oxygen while it was in the liquid state. These incidents, and others which might be recalled, are almost startlingly human in their nature.

INFANTILE MORTALITY IN STAFFORDSHIRE.

THE recently issued quarterly return of the Registrar-General relating to the three months ending with September last again records exceptionally high rates of infantile mortality in many of the urban districts of Staffordshire, more especially in the Pottery districts. The deaths of infants under one year of age during last summer quarter were equal to 177 per 1000 registered births in Hanley, 178 in Oldbury, 208 in Longton, 242 in Tunstall, and 288 in Burslem. In the 76 largest English towns during these three months the mean rate of infantile mortality did not exceed 145 per 1000; and in view of the following low rates that prevailed in other industrial towns—79 in Portsmouth, 85 in Halifax, 90 in Norwich, and 95 in Northampton—the waste of infant life in the above-mentioned Staffordshire towns stands out in striking contrast and gives additional interest to the remarks of Dr. George Reid, the medical officer of health of Staffordshire, in his last annual report for 1907. He therein points out that the rate of infantile mortality during last year exceeded 170 per 1000 in five urban districts in Staffordshire, Longton, Bilston, Brierley Hill, Darlaston, and Tunstall. While it is satisfactory to find that the rate in each of these five towns in 1907 showed a considerable decline from the rates that prevailed in recent years, Dr. Reid expresses doubt as to what proportion, if any, of this decline may justifiably be attributed to improved hygienic conditions or increased maternal care, having regard to the unquestionably powerful influence of the relatively low summer and autumn temperature that prevailed during 1907. With regard to the rate of infantile mortality in Longton, from information collected by the local lady sanitary inspector, Dr. Reid reports that the rate of mortality among wholly breast-fed infants during the year did not exceed 111 per 1000, while it was 147 among those partly breast-fed, and was no less than 442 per 1000 among nearly 200 infants entirely fed on artificial food. Dr. Reid has long maintained that the industrial employment of married women is one of the most potent factors in the causation of infantile mortality. He shows in his recently issued report that in eight Staffordshire towns, containing under 6 per cent. of married or widowed women out-workers, the rate of infantile mortality last year did not exceed 143 per 1000, while in 13 towns in which the proportion of women so employed ranged between 6 and 12 per cent. the mean rate was 154, and in five other towns in which more than 12 per cent. of the married or widowed women are engaged in work away from home the deaths of infants aged under one year were equal to 188 per 1000 births. These figures appear to support the asserted intimate relation between the proportion of married women employed away from home and excessive rates of infantile mortality. Dr. Reid's report, moreover, suggests that the recent decline in the still excessive rates of infantile mortality among the urban population of Staffordshire may in part be resulted in no great improvement on the original condition. He related a case in which the ureters had been implanted into the sigmoid flexure, but the latter became kinked with fatal issue. The operation done in Mr. Rigby's case was much simpler than many other operations and the shock was less.

Dr. G. A. SUTHERLAND showed a boy with Enlargement of the Liver and Spleen in which a diagnosis was made of Cirrhosis of the Liver. Mercury had been given.—Dr. CAUTLEY suggested that the rapid way in which it had yielded to mercurials suggested that the cirrhosis might have a syphilitic origin. Another possibility was that the child had some peritonitis, possibly tuberculous. He hoped that Dr. Sutherland would keep the case under observation and report upon it later. True atrophic cirrhosis was rare in children.—Dr. E. I. SPRIGGS said an important point would be as to whether the liver was nodular. He had not been able to feel the nodules himself but Dr. Sutherland had had an opportunity of examining the boy under more favourable conditions. The enlargement of the liver was not great; neither was the spleen larger than was sometimes found in cases of tuberculous peritonitis. He asked whether the temperature had been raised in the course of the illness. He did not think it was a case of Banti's disease as anæmia was not pronounced and the enlargement of the spleen was only moderate—Dr. SUTHERLAND defended the diagnosis of atrophic cirrhosis. He did not think that rapid improvement under mercury in such a case was sufficient evidence of syphilis. He thought it very likely that there was some perihepatitis and that the mercury had benefited that. The onset was sudden, with pain and distension of the abdomen. There had been no pyrexia. A short time ago there had been less fluid in the abdomen than at present and he had been able to feel that the liver was nodular and could feel no tuberculous mass. Although Banti had first shown the connexion between splenic anæmia and hepatic cirrhosis he did not think that this entitled the combination of these conditions to be known by his name. He thought it very unfortunate that the term had come into such common use in this country as a disease.

Mr. SYDNEY STEPHENSON showed a case of Ptosis Adiposa (blepharochalasis) in a child, aged seven years, the condition in which the upper eyelid drops over the eyelash.—Dr. SUTHERLAND passed round a photograph of a similar case which he had shown some years ago at the Society for the Study of Disease in Children. He had recently seen a case in which no benefit had followed an operation, and this patient developed marked spasm of the occipito-frontalis and a corrugated forehead, due to her efforts to raise the upper lid.

Dr. CARPENTER showed three cases of Congenital Deformity, of the skull, of the fingers, and of congenital dislocation of the hip, with specimens.

Mr. HUGH LETT showed a case of Facial Paralysis in a child, aged five weeks.

Dr. CARPENTER showed a case of Pseudohypertrophic Paralysis in a boy.—Dr. SPRIGGS remarked on the great diminution of muscular tissue in both the pseudohypertrophic and atrophic cases of progressive muscular dystrophy. He had found that this was associated with a very great diminution in the kreatinin in the urine and this afforded valuable evidence that kreatinin was mainly derived from muscular tissue.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Pityriasis Rubra Pilaris.—Oral Sepsis.—Lantern Demonstration.

A MEETING of this society was held on Dec. 2nd, Dr. JAMES RITCHIE, the President, being in the chair.

Dr. NORMAN WALKER exhibited a girl, aged 11 years, suffering from Pityriasis Rubra Pilaris as a rare and interesting case. He called attention to its superficial resemblance to psoriasis and to its insidious onset; it had also been confounded with ichthyosis, the skin being specially dry and hard on the knees. It was attended by the development of small papules around the hairs, and these ran together to form large map-like areas—erythrodermic areas. One observer had noted a relation between this disease and tuberculosis, and the patient exhibited was suffering from apical phthisis. The prognosis was not good and the condition as a rule lasted many years. The condition of the legs had improved under the action of weak salicylic vaseline ointment and good food with cod-liver oil and tonics. There was no specific treatment. Doubtless this was the same disease as that which Hebra described as lichen ruber acuminatus, and he affirmed that it invariably ended fatally unless arsenic was administered in large doses. Kaposi also employed this drug hypodermically.

A discussion on Oral Sepsis was opened by Mr. WILLIAM GUY who spoke as follows: It is well to remember that the mouth during extra-uterine life is never sterile. We have always present the bacteria which constitute the indigenous flora of the mouth and are not necessarily pathogenic; we find from time to time pyogenic organisms, staphylococcus pyogenes aureus and albus and streptococcus pyogenes and those which are concerned in the production of caries and of disease of the pulp, the various forms of leptothrix and bacillus gangrenæ pulpæ, and finally those which obtain fortuitous entry, such as pneumococcus, tubercle bacillus, and many other pathogenic organisms. The mouth affords the most favourable conditions not only for the multiplication of fission fungi and the production of their specific toxins but also for the emigration of septic material to other organs and the absorption of toxins. While I am prepared to maintain the thesis that a condition of sepsis in the oral cavity is of itself a sufficient deviation from health to claim the attention of physicians, surgeons, and dentists, I feel that the interest of members will be more concerned with the condition as a certain, probable, or possible factor in the causation of disease or as an intercurrent malign factor in the progress of other diseases. In spite of all that has been said or written, and particularly by Dr. William Hunter, I question if oral sepsis as the cause of septic gastritis is as frequently recognised as it should be. Why for countless ages has the tongue alone been subjected to a careful scrutiny? Why in histories of medical cases is the condition of the mouth ignored or alluded to in vague terms; the importance of observing and reporting on the condition of the mouth *quâ* sepsis should be insisted on. The physician may enlist the services of the dentist in the treatment of his cases, and I wish that the physician would always indicate what he expects the dentist to do and he should explicitly state what he wishes done—as, for example, to put the mouth in a thoroughly healthy condition, remove roots, treat decayed teeth, &c. Such an instruction from the physician would tend to the maintenance of a high scientific standard of professional work amongst dentists, not to mention the satisfaction that they would feel in being asked to coöperate with the physician. On the surgeon I would urge the necessity of attention to the hygiene of the mouth previously to the performance of any operation involving that cavity or any part of the digestive tract. I pause here to invite your views on oral sepsis as one of the principal causes of appendicitis. Rhinologists are, I believe, agreed that in suppuration of the antrum of Highmore the route of infection is much more frequently nasal than dental, but I should like them to consider the possible frequent infection of the nose from the mouth. Aurists must have many opportunities of noting infection of the middle ear from the mouth. In the treatment of pulmonary tuberculosis the condition of the mouth and teeth deserves careful attention. I believe that in the course of all acute diseases, and especially of the exanthemata, the presence or absence of oral sepsis is often the determining factor in the death or recovery of the patient. I should like to hear of some accurate observations being made in this connexion in our fever hospitals, especially in regard to scarlet fever. There is now provision made for medical inspection of school children. Dental caries is the most prevalent of all diseases. What is the good of inspection without treatment, and how is that treatment to be paid for? In the vast majority of school children I believe it is wiser to extract carious milk teeth than to attempt to fill them; better a clean mouth than a dirty one. I even question whether any tooth that has become septic in a child should be retained. In cases of septic adenitis I think the physician should advise the removal of any septic teeth, and I further think that the dentist would be wise to carry out the direction without hesitation or demur. The alienist will tell us, I hope, that the hygiene of the mouth is an essential part of the hygiene of the mind. I recall two cases of empyema of the antrum which produced profound the conclusion that there is a relation between the tendency to decay and chemical composition, the teeth most closely resembling human third molars being the least resistant to decay.

THE KING'S HEALTH.

As there have been disquieting rumours abroad we are glad to announce on the best authority that the health of His Majesty the King gives no cause for anxiety. When His Majesty left Windsor on Nov. 23rd he had a slight cold. He proceeded from Windsor to Castle Rising and thence in a few days to Sandringham. On arriving at Sandringham he showed symptoms of influenza and it was thought prudent that he should keep his room, only leaving it for his meals. On the third day he developed neuralgia with slight fluctuation of temperature. The condition improved under treatment, and as a change of air to the seaside was thought advisable His Majesty proceeded to Brighton on Dec. 8th. Up to the present he has derived decided benefit from the change.

FALSE PRETENCES AND FOODSTUFFS.

In a note in these columns on May 16th last upon the way in which certain benches of magistrates in Sussex dealt with cases of food adulteration that were brought before them it was suggested that the justices should look upon these cases as charges of obtaining money by false pretences. At Eastbourne proceedings were taken on Dec. 4th against a St. Leonards man for obtaining money by false pretences by means of the sale of "butter" which was found to consist of 50 per cent. of butter and 50 per cent. of margarine, and for attempting to obtain money by false pretences in a like manner on another occasion. The evidence in both cases was very similar, but the justices did not see their way clear to convict on the first summons but fined the defendant £5 inclusive of costs on the second summons—that of "attempting to obtain." As a rule, cases of this kind are based on Clause 6 of the Sale of Food and Drugs Act, 1875, the vendor being proceeded against for selling to the purchaser an article of food which was not of the nature, substance, and quality demanded. Although this carries with it a maximum penalty of £20 it does not provide for imprisonment and persons proceeded against under another Act will, perhaps, find that the mere payment of a fine—as a rule, a very small one to one who, perhaps, for a long time has been carrying on a very lucrative business—will not suffice. Nothing disparaging is meant to the Sale of Food and Drugs Act which is one of the finest Acts of Parliament ever placed upon the statute book, but unfortunately justices so often give alleged offenders the benefit of the slightest doubt that may arise in a case, or the defendant goes away scot-free on some technicality which may be raised by the defending solicitor on one or another of the four sub-sections of that well-known Clause 6. Exemplary punishment must be meted out to those individuals who not only palm off foodstuffs which are not of the nature, substance, and quality demanded, but are thereby breaking the law and doing a grave injustice to the genuine and honest trader who finds it very difficult in these days of keen competition at home and from abroad to make both ends meet.

We regret to announce the death of Professor Rindfleisch, the well-known German pathologist, who, succeeding his master, Virchow, in the appointment, occupied the chair of pathology at Würzburg for over 30 years.

The profession has also to lament the death of Dr. Charles E. Beevor, the well-known neurologist, who died on Dec. 5th quite unexpectedly. We shall publish an obituary notice of Dr. Beevor in an early issue.

ROYAL SOCIETY OF MEDICINE.

Debate on Heredity, with Special Reference to Cancer, Tuberculosis, and Disease of the Nervous System.—(*Concluded from p. 1702.*)

Mr. G. P. Mudge (London Hospital Medical College) said that one point which he wished to emphasise was the following. Sooner or later he supposed circumstances would compel medical men to approach the serious study of human inheritance. When they did so the first question which they must necessarily put to themselves would be, Which method would they employ? At present there were two schools of thought and two methods before the profession. One of those methods would be employed and the other would be inevitably rejected. The one school, that with which he did not agree, was the ancestrial or biometrical, and the other was the Mendelian. The first of those schools largely based their methods and their results upon the conception of continuous variations, they believed that new species arose by the piling up in successive generations of what was termed continued or fluctuating variations, and throughout the whole of biometric literature that had been emphasised, especially in Professor Karl Pearson's work on the Shirley poppies. The Mendelian school, on the other hand, took another standpoint. They did not refuse to recognise that fluctuating variations existed or that they played a certain part in the phenomena of living organisms, but they did not think that to any great degree those variations had taken part in the evolution of species. They contended that the evidence justified them in believing that species had evolved by the sudden origin of new characters. There was an idea abroad that necessarily those mutations or sports or large variations must be variations of large moment. That was not the Mendelian attitude: a mutation might be of quite small moment. Their point was that a mutation was a change which once having arisen would breed true. Continuous variations, on the other hand, did not breed true. The attitude of biometricians was emphasised by Professor Pearson when he said what was wanted was more pedigrees. Evidence of masses was the *sine quâ non* of the biometrician. He proposed to show how far the methods of the biometricians had succeeded and how far they had failed. On the other hand, the Mendelian did not care very much for masses, but he did care that he should have individual cases carefully studied and rigorously analysed. Having obtained a large number of analytical results they could deal trustworthily with the masses which were thus obtained. It was well to consider what the two schools had done. The biometrical school had been in existence for a long time, but the Mendelian school counted its birth from seven or eight years ago. Already the Mendelians had practically revolutionised agriculture and cattle breeding. With regard particularly to one case, wheat, the agriculturists sought to obtain a wheat which should have resistance to rust, which should have large ears and would ripen early. It was the great desire of agriculturists to get all those characters combined in one plant. Until the Mendelian came it was not possible to get that, but Mendelism had managed to get it, yet biometricians had been dealing with their mass results for years. Was there anything which the biometricians had done which justified the medical man in a single subject advising his patient as to what he should do? He believed Professor Pearson would not be able to produce a single instance which would justify a definite recommendation to his patient. But with regard to such a condition as brachydactylia the medical man could recommend a certain course in order to get rid of the abnormality. There was always a certain danger in making too confident a statement, but from the evidence one felt justified in predicting that the whole of the offspring from the union of a normal with an abnormal would be without the abnormality, and that when the condition had once disappeared it would never appear again. The validity of the judgment which Professor Pearson expressed concerning the series of albinos which was instanced depended wholly upon geographical circumstances and considerations. Albinos were fairly common in Scotland, compared with the frequency in other countries such as Norway, and the cases became able to express herself she complained of great pain *in her left side, but no pleural rub could be felt or heard* over the left base. The left eye became acutely inflamed and presented the features of an embolic and septic panophthalmitis. On the evening of the attack the axillary temperature rose to 101·2° F., the pulse to 126, and the respirations to 54 per minute. On the next day the thermometer did not rise above 97·4°; but in the death agony on the morning of Sept. 14th, about 70 hours from the seizure, 102·6° was recorded, the pulse being 148 and the respirations 52. She died at 5 P.M. on the 14th. A necropsy was made by Dr. W. Boxwell, the assistant pathologist to the hospital. He reports as follows: "On opening the pericardium a small amount of sero-fibrinous fluid was found within it. The heart itself was about normal in size and weighed 11 ounces. The visceral pericardium shows some subacute pericarditis, especially over the left auricle. On opening the chambers of the heart and washing out the clots the first thing noticed was an extensive acute vegetative endocarditis spreading over the wall of the auricle and continuous with a similar condition of the parietal cusp of the mitral valve. The wall of the auricle is considerably thickened over a circular area the size of a shilling and covered with vegetations. The auricular ventricular orifice is obstructed by shaggy vegetations *growing* from both cusps, especially the septal cusp. This cusp is also somewhat rigid and distorted. The orifice itself is, however, not *stenosed*, and *admits two fingers freely*. There is considerable thickness of the chordæ tendineæ, pointing to a previous chronic inflammation. The changes found in the spleen are *also* of some interest. It is enlarged and full of infarcts, some old *standing*, others more recent. One of them —a large reddish one—was suppurating, and an abscess, containing about an ounce of thick pus, was formed between the spleen, the overhanging and adherent liver, and a peritoneal fold. There was no generalised peritonitis. Some small infarcts in the kidneys, one of them recent and hæmorrhagic, were also noticed. There was nothing of interest in the lungs or other organs examined." The case illustrates the *distinction which* may be drawn between mitral narrowing, or stenosis, properly so-called, and mitral obstruction due to vegetations in and about what is really a dilated mitral orifice. It also *affords* a *striking* example of infarction and of septic embolism of the spleen.

Mr. L. G. GUNN exhibited an Unusual Thyroid Tumour which presented a perfectly smooth surface outside. On cutting into it it had the appearance of tuberculous affection, but the main thing *that struck* one was that quite large areas of calcification had taken place in the gland itself. About two months had elapsed and the patient showed no signs of myxœdema occurring. In some cases the entire thyroid had been *removed without its* occurrence. The sections under the microscope gave the impression that a carcinomatous change had taken place in the gland.—Sir CHRISTOPHER J. NIXON *thought* it was recognised not to be a justifiable procedure to remove the thyroid as a whole from the inevitable recurrence of myxœdema, as pointed out by the experiments of Horsley on monkeys. In Mr. Gunn's case there might be an accessory gland, which would prevent the myxœdema occurring.—Professor J. A. SCOTT said that one section appeared to be normal, but the other had a patch which might be anything. The gland was certainly not normal.—Professor A. H. WHITE said that the second section looked somewhat *suspicious*, but he would not like to say definitely that it was malignant.—Mr. GUNN, in reply, said that he did not think it necessarily followed that the entire removal *of the gland would be followed* by disastrous results. He did not think—in reply to a question by Dr. H. C. EARL—that the areas of calcification were true bone.

Dr. R. J. ROWLETTE and Mr. GUNN exhibited specimens of Sarcoma of the Intestine.

Dr. BOXWELL exhibited a specimen showing an Abscess in the Left Temporo-sphenoidal Lobe. The patient from whom the specimen was taken was a man who was admitted to Meath Hospital under the care of Mr. W. Taylor on Nov. 5th last. The history of the patient, obtained subsequently, was that he had suffered from a double suppurative otitis media from the age of seven and had continued to suffer for eight or nine years. The discharge *then ceased*, first on one side and then on the other, and he remained free from any sign of ear trouble until seven or eight months ago, when, without any cause so far as he knew, both ears began to discharge again. He was admitted to Meath *Hospital from Cork-street Fever Hospital*, where he *had been* undergoing treatment for typhoid fever. During convalescence he complained of headache for two or three days and then vomited almost incessantly for a day and a half. The character of the vomiting was cerebral. The discharge still continued. The *optic* discs were examined, but *no* evidence of "choked disc" could be detected. A few days previously to his admission to Meath Hospital, Dr. Davies, assistant to Dr. J. M. Day, had noticed some defect of memory, which was, however, only transitory. The patient had forgotten where he lived and what brought him to the hospital. The eyes were again examined but nothing abnormal could be seen. The pulse varied from 76 to 86 to the minute. The tension was normal and the temperature was 98°F. *When first seen at the Meath* Hospital the above history was not available, but the discharge from *both* ears was evident. The patient's intellect seemed quite clear. He answered *correctly* but with the faintest possible *suspicion* of hesitation or *slowness*. There was no complaint whatever of headache, even on inquiry. He *denied having* vomited and said that any *headache* he had previously suffered from was trifling. The pupils on both sides were quite normal and reacted readily to light. The reflexes in both arms and legs *seemed to be* normal. There was no impairment of movement of the eyeballs. No tenderness was felt on firm pressure anywhere over the head and no pain or tenderness was complained of on percussion over either side of the head. The temperature was 97·8°, the pulse was 80, and the tension was normal. Hearing that both optic discs were that morning found to be normal no further ophthalmoscopic examination was made. The condition remained unchanged for the next two days. It was at 9.30 P.M. on the 7th that the clear history of loss of memory and vomiting was first obtained from Cork-street Fever Hospital, and so it was determined that if the patient's condition was no better on the next morning an operation should be performed. At 2 A.M. on the 8th he became comatose and in this condition he was found by Mr. Taylor at 10 A.M. The pulse was 76 and the respirations were quiet. Touching his head anywhere caused the patient to move the *right leg and right* arm. There was no attempt at all to move either of the left limbs. The head was also turned to the left side on touching the left side of it. Trephining over the left temporo-sphenoidal lobe was at *once* proceeded with. This site was selected on account of the history of loss of memory noticed earlier in the case and of the slight difficulty which it was thought the patient exhibited in pronouncing his words on the evening on which he was admitted. *A large abscess* was readily found and drainage was provided. The pulse at once ran up to 140. The temperature one and a half hours after the operation was 101° but the patient remained comatose with widely dilated *pupils*. *At 6 P.M. his temperature* was 105° and the pulse-rate ranged from 130 to 140. On the next morning his condition was just the same and he died comatose 24 hours after operation. The necropsy revealed a temporo-sphenoidal abscess.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Meetings of this society were held *on* Oct. 22nd and Nov. 19th, Mr. P. E. Barber, the President, being in the chair.—Dr. Herbert G. M. Henry read a paper on Lumbar Puncture, its Diagnostic and Therapeutic Possibilities. He said that the lumbar *puncture* was *first* practised in England by Dr. W. Essex Wynter in 1889. Since that time the procedure had fully established its position in the armamentarium of the modern clinician. It was an operation entirely devoid of risk if aseptic precautions were adopted, and not only afforded valuable data in the diagnosis of many diseases but had also in certain cases a very decided therapeutic value. The pressure of the cerebro-spinal fluid varied greatly in normal conditions. In healthy persons in the horizontal position it averaged 125 millimetres water pressure, but in the sitting posture this might increase to more than 400 millimetres. Moreover, in pathological conditions it was sometimes impossible to determine how far a reading gave an index of the pressure of the fluid as a whole or only of a part shut off from the rest by adhesions. Normal fluid contained globulin and the presence in it of albumin was evidence of occurred, and therefore the proper general idea of the subject obtained. Mr. Mudge had been good enough to give a definition of an albino, and that test could only be applied in the post-mortem room. With regard to the tabby cats of London, of which Mr. Mudge had made a good deal, he asked that in every case dealt with exact numbers should be given. He reminded the meeting that when he spoke last he said nothing about his own pedigrees—he had now 800 of them collected; but he did say that the only definite evidence of albinism at present was from Norway and Sweden, and that Professor Bateson's cases told absolutely against the Mendelian point of view. He had not time to reply fully to Mr. Mudge's points, but he wished to suggest that there was a good deal more to be said about the subject than had yet been heard and upon more than one side.

Dr. W. **BULLOCH** said he knew very little about Mendelism or about Pearsonism, but he had been engaged in collecting for a number of years pedigrees which had been published of diseases in human beings, and he believed that he had as complete a collection as had ever been brought together, and he had handed it to Professor Pearson in connexion with his new treasury of human inheritance which that gentleman was bringing out and which should receive the support of all the members of the medical profession. Of all the pedigrees which had been incorporated into hospital notes and which had been published there were, perhaps, not more than ten, certainly not 20, which were complete and of great value. He illustrated the great difficulty which he had experienced in getting accurate data for pedigrees. He emphasised the need for pedigrees which were published being as complete as possible.

Mr. N. **BISHOP HARMAN** showed a series of slides and pedigrees of Lamellar Cataract by Means of the Epidiascope, and a series to illustrate the perpetuation through successive generations of a white forelock and white patch of skin spreading down the centre of the forehead.

Sir **WILLIAM S. CHURCH** (the President), in winding up the discussion, reiterated his assertion that the subject was inexhaustible and declared his belief that the discussion on it had been extremely interesting and somewhat profitable. There had been some wandering from the topic of the connexion there might be between heredity and disease. For instance, on the present occasion the discussion had been rather upon the heredity of colour and of form. He thought that he could very well congratulate the society on their first discussion since it had become the Royal Society of Medicine.

PROFESSOR KARL PEARSON AND THE LANCET.

In THE LANCET last week (p. 1708) we published a letter from Professor Karl Pearson repudiating entirely our report of his speech made at the debate on Heredity at the Royal Society of Medicine on Nov. 18th as inaccurate, and as having been "actually modified by some one with a totally different vocabulary before publication." But two persons, one an important participator in the debate, having told us that the report was substantially accurate we decided to compare our reporter's version in the places where Professor Karl Pearson repudiated him with the official version of the Royal Society of Medicine, as it was taken down, and with Professor Karl Pearson's version given in his letter as proof of the incapacity and insincerity of our report. We find our reporter's version tallies well with the version placed at our disposal by the Royal Society of Medicine, while both versions differ from what Professor Karl Pearson says that he said.

Our Reporter's Version.	*The Society's Version.*	*Professor Pearson's Version.*
1. All would agree about Dr. Mercier's remarks concerning mutations. His own view was that there was no truth in Mendelism at all.	1. He (Dr. Mercier) starts with an idea about mutation, which we all agree about, and that Mendelism has been true for something or other. My own standpoint is that there is no proof of Mendelism at all.	1. "Not all would agree with Dr. Mercier's remarks, &c., and that so far the truth of Mendelism has not been demonstrated for any one character."
2. I feared Mendelism of every form collapsed.	2. The principles required by Mendelism failed utterly.	2. I feared Mendelism and every theory hitherto proposed of heredity collapsed.

Professor Karl Pearson has impeached our accuracy, relying for the proof of his charge upon the version of his words to be published in the report of the Royal Society of Medicine. We suggest, in imitation, his own pleasant suggestion, that his words in that report will be "modified by some one with a totally different vocabulary before publication"—i.e., that having altered his words before publication in the report of the Royal Society of Medicine, he has brought a charge of inaccuracy against us because our version does not tally with what is going to appear in that report. If he has done this it seems to us a funny thing for a student of the exact truth to do.—ED. L.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of Newport (Mon.).—Dr. J. Howard-Jones calls attention to the difficulty which obtains at the present time in securing a really trustworthy local death-rate. As he points out, it is relatively easy to exclude from the local rates the deaths of persons dying within the district but who are not properly resident therein, but there is no proper organisation for including in the local death-rate the deaths of residents dying outside the district. He adds that during the last ten years he has only received information of the deaths of one Newportonian occurring in infirmaries and other institutions outside the town, a fact which, with a population of over 75,585, is sufficient to indicate that the present method of assessing local death-rates is incorrect and misleading. The voluntary notification of pulmonary tuberculosis has been in operation in Newport since 1893 and 110 cases have been notified since then. Of these 37 were alive in the borough on Dec. 31st, 1907. There were 85 deaths from this disease in Newport during 1907 and of these 23 had been notified—1 in 1905, 11 in 1906, and 11 in 1907. A block for the treatment of this disease has been recently erected at the isolation hospital. A female health visitor was appointed in 1902 and her duties comprise in the main visits to houses invaded by diseases such as whooping-cough, measles, and pulmonary tuberculosis. The water-supply of this important town does not appear to be altogether what it should be and mechanical filters have been fixed in the course of the mains from the reservoirs, a step which has had the effect of improving the appearance of the water. But it is added that all the supplies are from flood water sources and each one is liable to contamination from dwellings. The fishy smell which was complained of in connexion with the water from two of the reservoirs in 1905 when the water was treated with copper sulphate has not since recurred.

City of Chester.—The birth-rate of this city, with an estimated population of 39,420, has fallen more or less steadily since 1877, when it was 34·3 per 1000, to 24·7 in 1907, which was the lowest rate on record. There were in that year 1015 deaths and of these 40 were illegitimate. 15 births occurred in the workhouse and of these 11 were the illegitimate children of domestic servants. Dr. A. E. Thomas reports that the number of premature births in Chester is high and suggests the suspicion that the induction of premature delivery may be a deliberate act. The midwives of the city, on the whole, do their work "remarkably well; their bags of appliances are well-found, and their case books well kept. None are illiterate; though in many towns the opposite too often obtains." There were no deaths from puerperal fever during 1907. The recorded death-rate for 1907 was 16·5 per 1000, a higher rate than that which prevailed in the 76 great towns or in the 142 smaller towns. In discussing the diminished prevalence and fatality-rate of scarlet fever in Chester, Dr. Thomas asks how far the isolation hospital has contributed to this result. Wisely, however, he leaves his problem unsolved, merely indicating that he possesses an accurate general conception of the difficulties of the position. There can be little doubt that those institutions when properly constructed and properly administered are of material value, but no one who has studied the question in its broader aspects and who possesses in the least degree the mind of an epidemiologist would venture to assess statistically the precise value of these useful institutions. The town council of Chester is, we are glad to see, concerning itself with alcoholism as a public health factor and it has issued in the form of a placard the conclusions relating worth doing even if the continuity of the bladder and urethra could not be re-established. The advantages of prostatectomy done in two stages were emphasised where the symptoms were acute or the patient was suffering from sepsis.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 2nd, Dr. P. Boobbyer, the President, being in the chair.—Dr. C. Bell Taylor read a short paper on Cataract Extraction, in which he argued that iridectomy was better avoided, for it did not prevent prolapse of the iris and had other disadvantages. In some cases operation might wisely be postponed for a few years. For the actual extraction he used the spear-shaped pique de Pamard as causing less injury than fixation forceps and made the section of the cornea with a special trowel-shaped knife. The flap when completed included one half the cornea. Some patients operated on by Dr. Taylor were also shown.—Dr. C. H. Cattle read some notes on a case of Aortic Aneurysm, which caused the sudden death of a man aged 51 years. The signs, generally speaking, were latent in this case, for the cough and shortness of breath were much relieved by a few weeks' indoor treatment in hospital, hoarseness and complete paralysis of the left vocal cord alone remaining. Just as his discharge was contemplated a copious hæmoptysis occurred with fatal result. The specimen exhibited showed a small aneurysm of the descending portion of the arch which had ruptured into the left bronchus.—The President, Dr. F. H. Jacob, and Mr. H. B. Tawse discussed the case, and Dr. Cattle replied.—Mr. A. R. Tweedie read a short paper on the Middle Turbinal Body in Health and Disease in which he pointed out that the anterior end of the middle turbinal formed a protection to the openings of the frontal, ethmoidal, and maxillary sinuses respectively, as well as to the sensitive septum. He was strongly of opinion that total removal of the middle turbinal was better avoided. As the tissue covering the bone was a muco-periosteum lesions of the mucous portion were reflected more deeply as osteitis and this again tended to maintain œdema and hypertrophy of the mucous tissue overlying the bone and a thoroughly vicious circle was thus established. After tracing some of the secondary results of abnormal conditions of the middle turbinals Mr. Tweedie emphasised the benefit derived from removal of the anterior ends of the middle turbinals in certain cases. Cauterisation should, however, be avoided and operation should be strictly limited to what was really necessary.—Mr. Tawse had seen complete removal of the middle turbinals practised in a large number of cases without any apparent ill effects on the throat in consequence.—The President and Dr. J. Watson and Mr. J. H. Cox asked whether irrigation of the nasal passages was still considered advantageous, and Mr. Tweedie replied that it had been practically given up as useless, if not detrimental.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 27th, Dr. W. H. Cheetham being in the chair.—Dr. T. Wardrop Griffith read a paper on Some Forms of Cardiac Irregularity, with Observations on a case of Heart-block. The paper was illustrated by lantern slides.—Mr. J. F. Dobson read a paper on the Treatment of Acute Intestinal Obstruction by Intubation of the Intestine. The paper was illustrated by a number of cases upon which the operation had been performed.—Mr. G. Constable Hayes and Mr. G. P. Humphery showed a case in which a bullet had been removed from the nasal cavity after causing Detachment of the Retina; it was localised by x rays.—Mr. B. G. A. Moynihan showed a series of specimens from cases of Partial Gastrectomy. In many the change from a chronic ulcer to carcinoma was shown; the pathological changes, that is to say, corresponded with the clinical history. The after-results were referred to; one patient was alive over five years after operation and another over three years after. Colour photographs were also shown.—Mr. H. Littlewood showed a specimen from a case of Primary Ovarian Gestation.—Dr. A. G. Barrs showed a case of Multiple Peripheral Neuritis due to "diachylon" poisoning.—Mr. A. L. Whitehead showed a case of Chronic Empyema of the Antrum of Highmore in which the opacity of the antrum to transillumination persisted after the evacuation of the pus.—Mr. W. Thompson showed (1) a specimen of Malignant Tumour excised from the Kidney, and (2) a Blood-cast of the Ureter, 14 inches in length, many of which were passed by the patient from whom the specimen was removed.—Mr. R. Lawford Knaggs and Dr. W. H. Maxwell Telling showed a Tuberculous Kidney excised. During life there were no urinary signs but severe pain in the region of the affected kidney. A skiagram showed the kidney opaque to the x rays, suggesting the presence of numerous calculi. The diseased organ was entirely filled with caseous material, containing a large amount of gritty material.—Cases and specimens were also shown by Mr. E. H. Hackett, Dr. J. B. Hellier, Mr. A. S. F. Grünbaum, Mr. H. Secker Walker, Dr. E. F. Trevelyan, and Dr. A. D. Sharp.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Nov. 26th, Mr. D'Arcy Power, the President, being in the chair.—Mr. Edred M. Corner read a paper entitled "The Indications of Suppuration in Appendicitis." It was first demonstrated on physiological and anatomical grounds that the cæcum and appendix were the part of the alimentary canal where bacteria were placed under the most favourable conditions for growth, and hence inflammatory affections in this region were more likely to be followed by suppuration than in other parts of the gastro-intestinal tract. Mr. Corner insisted on the importance of remembering that in cases of appendicitis where there had been fever for four or five days suppuration was probably present. He also laid great stress on the fact that an abscess was usually present when a lump was felt by abdominal palpation over the appendix region in a case of appendicitis. He pointed out that cases of appendicitis which were of a severe type and were not operated upon often resulted in the formation of a local abscess. This abscess if it did not burst into the general peritoneal cavity and set up general peritonitis frequently would discharge itself into the bowel, usually into the small intestine. In conclusion he discussed the advisability of removing the appendix in cases of appendicitis which were operated upon for appendix abscess.—Mr. M. Fitzmaurice-Kelly read a paper on the Treatment of Urethral Stricture. The pathological changes in the mucous membrane and submucous tissue were discussed and illustrated by microscopical preparations, and the fact was emphasised that the essential changes occur in the submucous tissue, the mucous membrane being thickened and the epithelium approximating to the stratified squamous type. As regarded treatment Mr. Fitzmaurice-Kelly thought that intermittent dilatation was the method of choice in uncomplicated cases, and condemned rapid dilatation under an anæsthetic as dangerous and likely to be followed by a rapid recurrence of symptoms. The indications for urethrotomy were then discussed and preference was given to internal urethrotomy when possible, the roof of the canal being divided from before backwards, the operation of external urethrotomy being reserved for emergencies and certain circumstances that made internal urethrotomy impossible or inappropriate.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 4th, Colonel T. H. Hendley, I.M.S., the President, being in the chair.—Dr. S. D. Clippingdale read a paper upon West London Rivers, Extant and Extinct, and their Influence upon the Fertility and Salubrity of the Districts through which they Pass or Passed. Dealing with 14 streams, some of which no longer exist as open rivers but are converted into closed drains, Dr. Clippingdale showed their influence in producing the great fertility of Middlesex soil, the cultivation of which the Britons had been taught by their Saxon invaders. As a result the health of the district was benefited to a great extent by the abundant supply of root crops, fruit, and cereals. Scurvy, which formerly was prevalent in the metropolis, disappeared with the introduction of the potato into the market-gardens of Chiswick. On the other hand, these open streams in times of flood or of drought had fostered miasmatic diseases and the disease known as "London ague," formerly very prevalent, had disappeared with the closing in of such rivers as the Fleet, the Tyburn, and the Serpentine. By their influence on the land surface these rivers had also produced a series of clay hills and gravel valleys, experience and also statistics tending to show that it was better to live on a clay hill than in a gravel valley.—Mr. H. H. Miles, Mr. W. McAdam Eccles, and the President discussed the paper.

Newcastle-on-Tyne, Leicester, and in 45 other towns; the 47 uncertified causes of death in the 76 towns included, however, eight in Birmingham, six in Liverpool, four in Sheffield, and three in Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 17·3 and 16·4 in the two preceding weeks, rose again to 16·5 in the week ending Dec. 5th. During the first ten weeks of the current quarter the annual death-rate in these eight towns averaged 15·1 per 1000, and exceeded by 0·4 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 11·9 and 13·5 in Perth and Aberdeen, to 20·1 in Dundee and 26·9 in Greenock. The 583 deaths in the eight towns exceeded the number in the previous week by six, and included 53 which were referred to the principal epidemic diseases, against 68, 62, and 57 in the three preceding weeks; of these 53 deaths, 18 resulted from diarrhœa, 14 from whooping-cough, eight from diphtheria, six from scarlet fever, five from measles, and two from "fever," but not one from small-pox. These 53 deaths were equal to an annual rate of 1·5 per 1000, which exceeded by 0·3 the mean rate from the same diseases in the 76 English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had been 22 and 25 in the two preceding weeks, declined to 18 in the week under notice, and were fewer than in any week since the beginning of July; they included 12 in Glasgow, three in Edinburgh, and two in Dundee. The 14 fatal cases of whooping-cough showed a further slight decline from the numbers in recent weeks; eight were, however, recorded in Glasgow and two both in Dundee and Paisley. Of the eight deaths from diphtheria, an increase of three upon the number in the previous week, four occurred in Glasgow and two in Paisley. The six deaths from scarlet fever included three in Glasgow in which town also occurred four of the five fatal cases of measles. Of the two deaths referred to "fever" one each was returned in Glasgow and Greenock. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 136 and 133 in the two preceding weeks, further declined to 113 in the week under notice, and were 56 below the number returned in these towns in the corresponding week of last year. The causes of 23, or 4·0 per cent., of the deaths registered during the week in the eight towns were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 24·2 and 22·2 per 1000 in the two preceding weeks, rose again to 23·8 in the week ending Dec. 5th. During the first ten weeks of the current quarter the death-rate in the city averaged 20·2 per 1000, whereas the mean rate during the same period did not exceed 14·1 in London and 13·7 in Edinburgh. The 180 deaths of Dublin residents during the week under notice showed an increase of 12 upon the number returned in the previous week, and included 12 which were referred to the principal epidemic diseases, against 21 and 11 in the two preceding weeks. These 12 deaths were equal to an annual rate of 1·6 per 1000; the rate from these diseases in the same week did not exceed 1·0 in London and 0·6 in Edinburgh. Of the 12 deaths from these epidemic diseases in Dublin last week, five resulted from measles, three from diarrhœa, two from "fever," and two from whooping-cough, but not one from diphtheria, scarlet fever, or small-pox. The five fatal cases of measles showed a slight further decline from the numbers returned in the two preceding weeks; those of diarrhœa and of "fever" showed, however, an increase. The 180 deaths from all causes during the week included 40 of infants under one year of age and 50 of persons aged upwards of 60 years; the deaths of elderly persons showed a considerable increase upon recent weekly numbers. One inquest case and three deaths from violence were registered during the week, and 58, or 32·2 per cent., of the deaths occurred in public institutions. The causes of two, or 1·1 per cent., of the deaths in Dublin last week were not certified; the proportion of uncertified causes of death in Edinburgh last week was equal to 4·3 per cent., while in London the causes of all but three of the 1383 deaths were duly certified.

THE SERVICES.

Royal Navy Medical Service.

The following appointments are notified:—Fleet-Surgeons: D. J. P. McNabb to the *Prince George;* and J. A. Moon to the *Prince of Wales*, on recommissioning. Staff-Surgeons: E. S. Reid to the *Swiftsure;* and P. G. Williams to the *Vivid.* Surgeons: A. R. Fisher to the *Prince George;* and C. V. Griffiths to the *Prince of Wales*, on recommissioning.

Royal Army Medical Corps.

Major Lionel A. Mitchell, from temporary half-pay, to be Major, with precedence next below J. Hennessy (dated Nov. 21st, 1908).

Lieutenant Robert O'Kelly is confirmed in his rank.

Scottish Command, Edinburgh Company: Captain David Waterston resigns his commission (dated March 31st, 1908).

Special Reserve.

South Irish Horse: Surgeon-Captain Frederick Faber MacCabe is transferred to the Special Reserve, retaining his rank and seniority (dated July 7th, 1908).

Territorial Force.

Royal Field Artillery.

5th Staffordshire Battery, 3rd North Midland Brigade: Surgeon-Lieutenant Charles John Caddick resigns his commission as Surgeon-Lieutenant in the 2nd Volunteer Battalion, The South Staffordshire Regiment, and is appointed Captain (dated April 1st, 1908). 13th Lancashire Battery, 3rd Lancashire Brigade: Surgeon-Captain Francis William Bailey, from the 6th Lancashire Royal Garrison Artillery (Volunteers), to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 2nd Wessex (Howitzer) Brigade: Surgeon-Lieutenant Harold Frederic Bassano, from the 2nd Hampshire Royal Garrison Artillery (Volunteers), to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). 3rd Wessex Brigade: Surgeon-Lieutenant-Colonel Augustus Kinsey-Morgan, from the 1st Dorsetshire Royal Garrison Artillery (Volunteers), to be Surgeon-Lieutenant-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). 4th Wessex Brigade: Surgeon-Lieutenant George Clement Searle, from the 1st Devonshire Royal Garrison Artillery (Volunteers), to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908).

Royal Garrison Artillery.

Dorsetshire: Surgeon-Captain Telford Telford Smith from the 1st Dorsetshire Royal Garrison Artillery (Volunteers), to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

Infantry.

7th Battalion, The Duke of Cambridge's Own (Middlesex Regiment): The undermentioned officer from the 1st Volunteer Battalion, is appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain George Pester Chappel (to be supernumerary).

Royal Army Medical Corps.

Captain Herbert W. Whyte resigns his commission (dated Oct. 27th, 1908). Major Joseph G. Turner resigns his commission (dated Nov. 2nd, 1908).

1st North Midland Field Ambulance: Frederick Russell Bremner to be Lieutenant (dated Oct. 2nd, 1908).

3rd North Midland Field Ambulance: Philip Watson Turnor to be Lieutenant (dated June 12th, 1908).

1st Eastern General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated May 6th, 1908):—To be Lieutenant-Colonels: Sir Thomas Clifford Allbutt, K.C.B., F.R.S., George Edward Wherry, John Buckley Bradbury, and Frederick Deighton. To be Majors: Laurence Humphry, Arthur Cooke, Ernest Lloyd Jones, Frederick William Burton-Fanning, Hamilton Ashley Ballance, John Aldren Wright, Peverell Smythe remarks on huts and married quarters. This chapter, indeed, omits nothing of importance. The author enters on the subject of water-supplies, the amount, sources, the comparative qualities of water-supplies, storage and delivery, impurities and the effect of drinking impure water, and the means whereby water may be purified and rendered fit for consumption. The principles of diet now engage our attention before the ration of the soldier is considered; the latter is detailed with respect to its issue in times of peace in hot countries and in war. The cooking of the food, the diseases connected with food, and remarks on the various articles of food complete this section. The subject of alcohol is concisely entered upon. The methods of clothing the soldier, his equipment, and his work, and the questions relating to marching and the camp complete the work.

From the above remarks it will be seen how admirably Lieutenant-Colonel Firth has fulfilled the task which he has undertaken. We doubt not that this book will be in the hands of all concerned, for hitherto no such valuable compendium of all that relates to our army has appeared.

A Manual of Bacteriology. By HERBERT U. WILLIAMS, M.D., Professor of Pathology and Bacteriology, Medical Department, University of Buffalo. Revised by B. MEADE BOLTON, M.D., Professor of Pathology and Bacteriology, University of Missouri; Bacteriologist, Bureau of Animal Industry, &c. With 113 illustrations. Fifth edition, revised and enlarged. London: Rebman, Limited. 1908. Pp. 466. Price 9*s.* net.

SINCE we last reviewed this work it has increased in size from a small book of 290 pages to one containing nearly double the number, and now, in its fifth edition, takes its place amongst the numerous standard works on bacteriology which are intended primarily for the use of medical men and medical officers of health. In scope, arrangement of material, and general treatment of the subject, it differs in few respects from its numerous competitors. Originally intended to serve as a laboratory manual for the unaided student it still bears traces of this purpose in the large amount of space devoted to bacteriological technique and biology of micro-organisms; only one-third of the book is occupied with the detailed description of pathogenic micro-organisms. The original idea has now apparently been abandoned and the book opens with the statement that "Bacteriology is not a subject which one should attempt to learn from books alone or without instructors"—a statement with which we heartily agree. A somewhat dogmatic method of expression adopted deliberately, and we think wisely, as being best adapted for the student is a second distinguishing feature of the book. This attitude is, to a certain extent, apologised for in the preface and, of course, disarms criticism. The book has been thoroughly revised and additions have been made where required by recent advances in knowledge; some of these additions are, however, so stated that they suggest that the person responsible for them has been out of touch with clinical medicine.

Considerable alterations have been made in the chapters dealing with milk, water, and disinfectants. These subjects are treated rather fully for a work of this size and character. The section on milk is good and contains many useful facts, and a definite, though not dogmatic, opinion is expressed in favour of pasteurisation as the best safeguard of the supply. The section devoted to water is too brief to be of much service except as an introduction to the subject but it is remarkable for the doubt cast on the value of any chemical or bacteriological analysis of water. This opinion appears to be shared by the reviser who is well qualified to speak on this point.

The chapters on immunity and allied subjects were always good and now present a very complete view of Ehrlich's theory and its modifications, together with a discussion of the question of deviation of complement.

The part of the book which deals with the pathogenic organisms is of average excellence and as numerous references to original work are given in this book the student can easily acquire further information. The fashion of attaching the name of the observer to each piece of information adds reality to the statements but rather tends to produce disjointedness in the treatment of the subject. It would seem, too, that there must be much vain repetition in medical work as a reviewer becomes painfully aware that there seem to be more observers than facts observed. A short account of the pathogenic protozoa completes the work. The illustrations are numerous and are for the most part reproductions of good original photographs.

The book is of neat appearance but seems to have been prepared for the press hastily. It is always difficult to distinguish between error and a difference in custom when dealing with misprints in an American book, but there is an error in the reference to an illustration on page 106, and "gemical" (? germicidal), "predisfusition," "sterptococcus," "slought" (? slough), "methplene" (? methylene), and so on, are unusual variations in spelling. The book is printed in America.

LIBRARY TABLE.

Lists of Muscles for Electrical Testing. London: H. K. Lewis. Price 2*s.* 6*d.*—*The Maternity Nurses' Charts and Case-Book.* By GERTRUDE C. MARKS. London: Baillière, Tindall, and Cox. 14 charts. Price 1*s.* net.—These two publications are compiled to facilitate case recording. The first contains a number of detachable pages gummed on one side and printed on the other with the names of various nerves coupled with the muscles supplied by them, with blank spaces for the records of electrical reactions. The sheets are of three kinds, dealing with the lower limb, the upper limb, and with the head, neck, and trunk respectively. They should prove a useful accessory to the neurologist's case-book. Miss Marks's "Maternity Nurses' Case-book" is arranged so that the complete record of a case is seen at one opening. On one page are a 14 days' morning and evening temperature chart with blank lines for the progressive weight of the baby and the usual information concerning the patient, whilst the opposite page is ruled for the entry of "dates" and "remarks." It is a handy little book and its intelligent use should have an educational value for the nurse.

Interim Report on the Parasites of Grouse. By A. E. SHIPLEY, M.A., Hon. D.Sc., F.R.S., Fellow and Tutor of Christ's College, Cambridge.—It was with pleasurable anticipation of an hour's interesting and instructive reading that we opened the pages of the Interim Report of the Grouse Disease Inquiry. We were not disappointed and soon were absorbed in following the description of the parasites of this popular little bird. The report is based mainly, we are told, on the author's own observations, in which he was very ably assisted by Dr. E. A. Wilson and Mr. J. C. F. Fryer of Caius College, of whom also he mentions that many of the facts were first noticed by them. The investigations were largely carried out in the very home of the birds in different parts of Scotland. Outbreaks of disease were investigated actually in their immediate neighbourhood, a laboratory oftentimes being improvised in a stuffy back room of an inn. It was noted by Dr. Shipley that the disease universally referred to by gamekeepers as "the" grouse disease was caused by worms, hence the importance of the subjects embraced by this report. The parasites are presented under hence have contributed unmistakeably to the advancement of their science."

It is true that women enter the lists on equal terms with men as regards education, inasmuch as they pass the same examinations, and in some schools they have equal opportunities of working, both in laboratories and in hospitals, with this important exception, that resident students' posts are, as a rule, withheld from them. After they are qualified the handicapping of medical women becomes more apparent, for they are rarely admitted to resident posts at general hospitals and so are debarred from experience and teaching which are of incalculable value, for it is agreed that all specialised training should be preceded by thorough general knowledge. Besides this want of experience, women have few opportunities of becoming familiar with research methods, and of using instruments and apparatus which are beyond the reach of ordinary private individuals, but which are at the service of resident hospital officials. The suggestions and stimulus given by senior physicians and surgeons must be of great value also.

It seems to me improbable that eminent surgeons of the present day would have acquired their remarkable skill if, at the beginning of their careers, they had been unable to obtain constant practice as house surgeons and resident surgical officers; and it seems equally improbable that famous physicians of the present day would have done so much to advance their science if they had been unable to make observations on large numbers of hospital patients. I do not presume to discuss the suitability or unsuitability of women for the medical profession but only wish to point out that they are by no means on equal terms with men as regards continued education after they have passed a qualifying examination.

I am, Sir, yours faithfully,

Dec. 5th. MARY CLARKE.

STANDARDISATION OF DISINFECTANTS.

To the Editor of THE LANCET.

SIR,—May we be permitted to associate ourselves with the view expressed by yourselves in your issue of Dec. 5th? Any movement for the constitution of an independent board of experts for the standardisation of disinfectants would have our undivided support, as the present position is entirely unsatisfactory. Any departure from standard conditions should not be allowable without mature consideration; for instance, the futility of this latest modification suggested by Rideal and Walker will be apparent if comparative tests are made with disinfectants in natural waters, such as have commonly to be used, as compared with distilled water.—Yours faithfully,

NEWTON, CHAMBERS, & CO., LTD.,
(W. NEWTON DREW, Managing Director.)

Thorncliffe, near Sheffield, Dec. 7th, 1908.

THE CAUSE AND PREVENTION OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—The editor of the *Dental Surgeon* indicates that I seem "to think that the value of hard and resistant food and general exercise of the jaw muscles as prophylactics against dental caries is a new discovery" and refers to Coleman's "Manual on Dental Surgery and Pathology." What are the views to be found on the pages referred to? The following extracts indicate what they are:—

> One of the chief causes of this degeneracy [of the teeth] we believe to be the change, both in character and mode of preparation, which the food of man has undergone during the last few centuries. Take, for instance, his bread; this, as compared with that of the present day, was imperfectly ground and contained a larger proportion of husk of the grain, and, in consequence, a larger proportion of phosphates. ...... Organs or structures not properly exercised undergo, after it may be many generations, some form of degeneration, and it is only reasonable to conclude that the teeth and jaws follow the same law; the former unprotected losing their power of resisting external agencies. ......

This is a clear statement of one of the theories which I have tried to combat. I have consistently opposed the idea that the teeth are undergoing any degeneracy on account of lack of sufficient use. If the degeneracy theory were correct the hope of regaining perfection in our teeth would only be but a remote one, instead of being within the immediate power of every intelligent parent. Again, the old dietetic theory might lead to distinct and serious error. Thus, for example, fine biscuits, toffee, and bon-bons of various kinds may stimulate mastication and therefore might be supposed to develop and strengthen the teeth so that they would be able to resist external agencies. The truth is, however, in my view, that such foods tend to stick about the teeth and undergo rapid fermentation, so that caries is the inevitable result. Nor did the degeneracy theory in any way suggest one of the most important provisions in the new method of prevention—namely, that the meal should be so arranged that the last part of it should leave the mouth physiologically clean. In other words, that if a meal has included sweets or sticky carbohydrates these should be followed by some detergent food or drink, such as, for example, fresh fruit or a cup of coffee. It is one thing to contend that the refinement and softening of food tend to make it lodge unduly about the teeth and undergo acid fermentation, and quite another to say that this refinement and softening deprive the teeth of their proper share of phosphates and blood for their proper development. I am, Sir, yours faithfully,

Wimpole-street, W., Nov. 29th, 1908. J. SIM WALLACE.

To the Editor of THE LANCET.

SIR,—I notice that Dr. R. W. Allen in his interesting paper on the Common Cold gives a prescription for a gargle containing a certain amount of free hydrochloric acid. My attention was drawn to the subject of hydrochloric acid in gargles by the fact that a patient presented herself to me for dental treatment last spring showing a large amount of dental caries, from which heretofore she had been fairly free. I inquired whether she had been taking any medicine, but she said that she had not but had been using a gargle. Upon seeing the prescription I found it was a very similar one to the one mentioned in Dr. Allen's paper.

We know that mineral acids, even when very dilute, have a decalcifying action on the enamel. Furthermore, a gargle if used properly must necessitate the liquid being held in contact with the back teeth for some considerable time, much longer than when medicine is swallowed. It is, therefore, reasonable to suppose that an acid gargle is more injurious to the teeth than an acid draught, while the former cannot be taken through a tube like the latter.

I would suggest that instructions should be given to patients taking any mineral acids into the mouth to rinse the mouth well afterwards, preferably with an alkaline solution. I have seen a similar condition in the mouths of two members of one family who had dosed themselves freely with dilute phosphoric acid as a remedy for colds.

I am, Sir, yours faithfully,
WM. RUSHTON, L.D.S. ENG.

Harley-street, W., Dec. 7th, 1908.

A SERUM TREATMENT FOR CARCINOMA IN MICE.

To the Editor of THE LANCET.

SIR,—It has been represented to me that there are some who think that in my criticism of Mr. C. E. Walker's paper and in my letter published in THE LANCET of Nov. 21st I expressed myself in terms more forcible than was necessary in the circumstances. I am glad, therefore, to take the earliest opportunity of saying that I am sorry if I put forward my views in a manner that could give rise to such a feeling. I should also like to express regret if I have placed Mr. Walker and my colleagues on the council of the Liverpool Medical Institution in a position open to misconstruction by my remark that the former "asked to be invited." I was away from home at the time, but I understand that what happened was that Mr. Walker stated through the secretary that he had some work which he would like to bring before the members of the institution. This communication was considered by the council, as to ways and means, with the result that Mr. Walker was unanimously invited to read his paper at an ordinary meeting, a full discussion being arranged for. I learned this unofficially on my return home.

I had intended not to discuss the subject further, but I feel that I owe it to myself to establish my good faith in the scientific aspect of the matter under discussion. There is, however, only one point left which requires elucidation, and the collar the operator is enabled to estimate correctly, without any chance of error, the exact depth to which the chisel has penetrated, an advantage which will be appreciated. With the chisel properly held a cut ¼ in. in depth will penetrate one-half the distance through the sphenoidal sinus. This opening is as large as that made into the sphenoidal sinus by the usual means—namely, a stout curved pointed knife which is entered into the natural outlet of the sphenoidal sinus for the purpose of enlarging its opening, through which opening is introduced a punch worked with strong levers whereby the desired portion of bone is removed. I would ask readers of THE LANCET to compare the complications which are liable to be encountered by the two methods of performing this operation. With the chisel there is no blood to obscure the vision until after the chisel has been properly placed, subsequently to which there is no necessity to look into the nose. With the stout curved knife, apart from the great difficulty of entering the natural opening of the sphenoidal sinus, the parts are obscured with blood from the first moment that the knife comes in contact with the mucous membrane. When there is any difficulty in effecting the removal of this chisel or when it is desired to increase the lateral measurements of the opening made, a set nut with a projecting hub is adjusted with the fingers over the thread on the proximal end of the rod. The projecting hub is turned towards the proximal end of the rod and the nut is screwed down on the rod for one half an inch. There is also a round handle ⅜ in. in diameter and two inches in length, which has an opening partly through its middle. A thread is cut in this opening which allows the handle to be screwed on to the proximal end of the rod with the fingers. When the handle is fully screwed down the set nut is unscrewed until its hub binds against the handle. The operator is thus furnished with means whereby he can readily remove the chisel or increase the lateral dimensions of the hole in the sphenoidal sinus to ¼ in. by twisting the rod through an angle of 90 degrees. Operators are advised to inspect the sectional skull before performing this operation. Messrs. J. Weiss and Son, 287, Oxford-street, London, W., manufacture the instrument.

CHARLES AUBREY BUCKLIN, M.D.

BRITISH MEDICAL BENEVOLENT FUND.

AT the November meeting of the committee 22 cases were considered and grants amounting to £180 were voted in relief to 18 of the applicants, two cases being passed over and two postponed for further inquiry. Appended is an abstract of the cases assisted:—

M.B., C.M. Edin., aged 66 years, who practises in Lancashire. Applicant's receipts during the last two years have seriously decreased owing to competition, depression in trade, and the number of medical institutions, and he is unavoidably in arrears with his rent. Three children, aged 19 to 10 years, one being an invalid. Voted £12.

Widow, aged 48 years, of L.R.C.P., L.R.C.S. Edin. No income. Since husband's death has partially maintained herself by nursing but is at present unable to work on account of ill-health. Three children, just self-supporting. Relieved 14 times, £144. Voted £12.

Daughter, aged 53 years, of late M.D. Lond. No income. Lets lodgings. Health indifferent. Relieved 25 times, £190. Voted £6.

Daughter, aged 61 years, of late M.R.C.S., L.S.A. For many years acted as housekeeper for two sisters who have kept a school, but changes in the neighbourhood have compelled them to give it up. Income less than 10s. a week. Voted £12.

Widow, aged 70 years, of L.S.A. No income. Dependent on two daughters who can ill afford to help. Voted £12.

Daughter, aged 52 years, of late M.D. Edin. No income. Dependent on letting lodgings and has had a very bad season. Relieved once, £12. Voted £10.

L.R.C.P., L.R.C.S. Edin., aged 51 years. No income; incapacitated by spastic paraplegia. Has been living by selling his furniture. One son, aged 12 years. Relieved four times, £48. Voted £12.

Widow, aged 52 years, of L.R.C.P., L.R.C.S. Edin. No income; seven children, aged 22 to 11 years, one being an invalid and one mentally deficient. Slight help from three eldest sons. Relieved twice, £24. Voted £12.

Widow, aged 44 years, of L.R.C.P., L.R.C.S. Irel. Quite unprovided for at husband's death three years ago and now works as a parish nurse, but not being strong cannot command sufficient salary for unavoidable expenses. No children. Voted £5.

Widow, aged 68 years, of L.R.C.P. Edin. No income; children unable to help. Health feeble and eyesight failing. Relieved once, £12. Voted £12.

Daughter, aged 54 years, of late L.S.A. Has supported herself for many years as a governess or companion, but is now in very bad health and unable to undertake any regular work. Relieved seven times, £63. Voted £12.

Widow, aged 57 years, of L.R.C.P. Edin. Six children but only able to give slight help and a grant is sought to provide the youngest son with a suitable outfit for a post which he is promised. Relieved twice, £15. Voted £10.

Widow, aged 71 years, of M.D. Lond., L.R.C.P. Income less than £1 a week and applicant asks for a little help to obtain a few small comforts which at her age she greatly needs. Relieved three times, £21. Voted £5.

Daughters, aged 56 and 43 years, of M.R.C.S., L.S.A. No income and dependent on earnings from needlework and slight help from a relation who can ill afford it. Relieved four times, £44. Voted £12.

Wife, aged 63 years, of M.R.C.S., L.R.C.P. Deserted by her husband five years ago through no fault of her own and is without any means. Endeavours to support herself by needlework and receives a little help from friends. No children. Relieved once, £12. Voted £12.

Daughter, aged 65 years, of late M.R.C.S. No income and in very bad health. Relieved twice, £20. Voted £10.

Widow, aged 71 years, of L.F.P.S. Glasg. Five children, aged 45 to 35. Is a candidate for the Epsom College annuity and hopes to be elected shortly. Relieved twice, £17. Voted £2.

Widow, aged 62 years, of L.F.P.S. Glasg., who was an annuitant of this fund. No means, small earnings by knitting; indifferent health Relieved once, £12. Voted £12.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Dec. 11th, 1830.

HEADACH CAUSED BY THE PRESENCE OF A SCOLOPENDRA IN THE FRONTAL SINUS.

WE extract the following case from the report of the "Societé des Sciences Médicales, du Department de la Moselle."

A farmer's wife, twenty-eight years of age, residing in the neighbourhood of Metz, had for a long time been affected with an unpleasant itching sensation in the nose with coryza, to which symptoms in the year 1827, violent headach acceded, so that she was at length obliged to apply for medical aid. The headach was irregularly intermittent, and generally began at the root of the nose and the middle of the forehead, or at the right frontal region, extending thence first to the right side, and then over the whole head. The attack was accompanied by a great discharge of tears, and sometimes even nausea and vomiting; the features were forcibly distorted, the jaws firmly closed, and the eyes and ears so very sensible, that she could not bear the least light or any noise. At other times she became delirious, pressed the head between her hands, and ran about in a state of distraction. The pain was, according to her statement, like the strokes of a hammer, or as if something was perforating the skull, and the fits generally returned about twelve times in twenty-four hours; sometimes the headach continued uninterruptedly for several days. The coryza existed during the whole period and the discharge was occasionally very fetid and mixed with blood. Some medicines were employed, but no regular plan of treatment was followed, and it was not before a twelvemonth's suffering that this singular affection terminated, after the expulsion of a worm from the nose, which moved with rapidity, and when placed in water, remained alive for several days; it was afterwards killed by being put in alcohol, and sent to M. Maréchal, who reported the case to the Society. He found the animal to be more than two inches in length, and one line in breadth; it had two antennæ, was of yellowish colour, flat, and consisted of sixty-four rings, on each of which were two legs. M. Maréchal subsequently transmitted the insect to MM. Hollandre and Roussel, who ascertained that it was a scolopendra electrica.

BERI-BERI AT CARDIFF.—An inquest was held at Cardiff on Dec. 4th relative to the death of a Lascar seaman who had died at the Seamen's Hospital. The medical officer of the institution stated that he believed that the deceased had been suffering from beri-beri and that death resulted from syncope. The jury returned a verdict in accordance with the medical evidence and the coroner directed that the sanitary authorities should be informed that a case of beri-beri was believed to have occurred upon a ship coming to Cardiff.

Let examinations be based on this principle and combine with them a system of apprenticeship—to a hospital, not to an individual,—give two-thirds of the marks for the apprenticeship work and one-third for the examination work, and then a man will be able to acquire a sound practical knowledge of his profession. The whole question is one of national importance. I am, Sir, yours faithfully,

M.A., M.B.

ANAPHYLAXIS.

To the Editor of THE LANCET.

SIR,—May I ask you or some of your readers who may be better instructed than myself how the word "anaphylaxis" came into being? It was, I believe, coined by Dr. Charles Richet and means (I gather from an article on the subject in the *Journal of the American Medical Association* of Nov. 7th) hypersusceptibility. If this is so, how does that meaning arise from the word anaphylaxis? Is the *ana* the alternative form of the α privative and, if so, why not have made the word aphylaxis on the model of aphasia, atrophy, or agraphia? Of course, the α before a vowel becomes αν as in anæmia. If, on the other hand, the *ana* is the preposition the word should mean "repeated protection" or "increased protection." I shall be grateful for any information on the subject. If anaphylaxis does mean "without protection" it is easy to see whence arises the idea of "increased susceptibility." I am, Sir, yours faithfully,

Dec. 7th, 1903. ETONENSIS.

PROPOSED MEDICAL REFORMS IN NORWAY.

(FROM A SPECIAL CORRESPONDENT.)

THE report is now to hand of the medical commission appointed to inquire into suggested reforms in connexion with medical men, midwives, and quacks, and also to investigate further the proposed "doctor paragraph" in the new criminal code which enacts that the refusal of medical men and midwives to attend urgent cases should be made an offence punishable by law. This paragraph aroused much opposition in the Storthing and threatened the new criminal code with danger. It was therefore decided that the paragraph should be omitted and that the matter thereof should instead be treated by the medical commission, together with other proposed legislation dealing with the rights and duties of medical men generally.

After discussing the criticism by the Storthing of the "doctor paragraph" the commission expresses its doubts as to what extent and in what cases compulsory attendance on patients can be forced on the medical profession. The objection to the inclusion of the paragraph in the criminal code must surely cease to exist when it forms a link in a special law affecting the rights and duties of medical men. But not even in such a law should any condition be imposed that experience has not proved to be satisfactory to the community. The commission finds that not only must the need for immediate attendance by the medical man be recognised by those concerned but also that he himself must be convinced of this same need. Should a medical man's liability to attend, as in the "doctor paragraph," be unlimited, provided that the demand for aid be pushed, many difficulties and much unpleasantness would arise, especially in country districts where attendance on patients out of their turn may be imperative.

If the principle underlying the "doctor paragraph" is to be realised (as the commission thinks it should be) the conditions under which a medical man is bound to attend must be carefully defined and confined to accidents and childbirth. Under these conditions his duty would be plain both to himself and the patient, and urgent cases would be attended to in preference to others. The medical faculty, it is presumed, cannot take exception to such a plan, limited as it is to what is already practised by every right-thinking medical man. Should the aid thus given not be paid for by the parties concerned payment is to be made by the municipal authorities in the patient's district, these authorities in their turn having the right to seize the property of the recalcitrant patient if need be. Further, in the interest of public health, a medical man in attendance on an epidemic or infectious illness that is the subject of official control is to notify such a case and to prescribe such measures as are required to limit the spread of the disease.

By the present law the King may grant the right to practise medicine in Norway to one who has not passed the country's medical examinations but who in other respects has proved his knowledge of medicine. It is proposed that the King shall retain this privilege but that the candidate for a licence to practise shall pass a test imposed by the medical authorities. This condition is, however, not to be applied in the case of foreigners appointed as teachers by the medical faculty or in the case of foreigners wishing to practise only among their fellow countrymen or wishing to undertake purely scientific research work, such as the study of leprosy. There is nothing in the present Norwegian law to insure to a medical attendant priority of right in bankruptcy claims or after the death of his patient. In many disputed cases, however, it has for a long time been the custom to allow medical men priority of claim, and it is now proposed to make this practice law. This priority of claim is not only to include ordinary fees for attendance but also all charges in connexion with consultations, operations, and medicaments. The claims must not, however, date back more than a year from the declaration of bankruptcy or death of the creditor or patient.

With regard to professional secrecy, the commission finds that a medical man's privileges in this respect should be clearly defined by law, and in order that the sacredness of private life insisted on by the public when confiding in a medical man should be respected it is proposed that the privilege of professional secrecy shall not only include confessions made by a patient but also all information acquired by professional independent observations. On the other hand, a medical man is to be free to disclose information acquired in connexion with examination for insurance or for an official appointment, should such information be required by the parties concerned. The privilege is also to be a dead letter in cases of identification, &c., by a medical man called in as an expert.

According to the present law a practitioner may not be deprived of his licence unless he has been convicted of a punishable offence. Thus in the case of a medical man's insanity or excessive use of morphine there is no effective method to prevent his practising, however great the danger may be to the public. In such circumstances it has been the custom of the medical faculty's administration privately to request the practitioner concerned to cease to prescribe certain drugs, &c. This must be considered an unsatisfactory practice, depending as it does on the good-will of the parties concerned. Legislation is therefore required which will deal satisfactorily both with the interests of the public and those of the medical man whose livelihood is threatened. It is proposed that a practitioner who is considered unfit for medical practice on account of insanity or mental weakness shall be deprived of his licence where judgment has been so given after an exhaustive inquiry by the Government's medical department. In the interval, before judgment has been given, the King is to be authorised temporarily to suspend the licence of the medical man in question.

At present there are no special laws regulating dentists and their work, and licence to practise is given by the King in accordance with the "quackery law." As this practice is unsatisfactory it is proposed that the special licences should no longer be given, the licence only to be acquired after passing the requisite examination, the candidate being over 21 years and undertaking to carry on his work honourably and conscientiously. Professional secrecy and liability to suspension are to be the same as for medical men. A midwife's obligation to attend at once on all cases irrespectively of persons and the prospect of payment has been severely criticised by the Society of Midwives. The commission therefore proposes that a midwife shall be able to claim debts from the municipal authorities on the same terms as a medical man whose attendance has been compulsory.

Finally, the commission deals with the quackery question which has recently been much discussed in the medical press, quack advertisements in the daily press having been severely commented on. Admitting the correctness of the medical attitude in this respect and the advantages to be obtained by repressive legislation against quackery, the procedure for the closing of uninhabitable houses laid down in Section 32 of the Housing of the Working Classes Act, 1890, has been amended in an important particular. Under the Act of 1890 a closing order can be made by the justices on the application of the local authority, which in its turn usually makes such application upon the report of its medical officer of health. Clause 13 of the Bill dispenses with the reference to the justices and enables the local authority to make an order prohibiting the use of a dwelling-house for human habitation until in the judgment of the authority the house is rendered fit for habitation. The closing order may be determined by the authority if the house is made fit, and the owner may appeal to the Local Government Board if his application for such determination is refused by the authority, and he may also appeal to the Board within 14 days of the closing order being served upon him. The amendment which the Committee has added to this clause makes it compulsory upon the Local Government Board to hold a public local inquiry before dismissing appeals made to the Board under the clause, but even so the clause, when operative by law, should prove of immense aid to practical sanitarians. Clause 35 enables the Local Government Board to make rules to determine the procedure of these appeals and before considering any appeal the Board may require the appellant to deposit such a sum as will cover the cost of the appeal. The success or failure of Clause 13, giving as it does greater facilities to local authorities in the closing of uninhabitable houses, will depend in great measure upon the rules which the Board frames under Clause 35 of the Bill and also upon the personality of the official who holds the public inquiry. A large number of local authorities, more especially in the rural districts, are not at all anxious to have cast upon them the responsibility of closing houses owned, maybe, by their friends or neighbours, and they will not be adverse to the power of appeal being exercised in order to take from their shoulders any odium attached to the making of compulsory closing orders. The process of appeal must therefore be made as simple and inexpensive as possible, and the official who inquires into the circumstances must be one who not only has had experience in the administration of the Housing Acts but he must be familiar with those conditions that are to the detriment of a house, and he must be able to state in a convincing manner his reasons for supporting, or dissenting from, the action of the local authority.

A county council is enabled to appoint a medical officer of health under Section 17 of the Local Government Act, 1888, and Clause 57 of the Bill makes such an appointment compulsory. Under the same clause the Local Government Board may prescribe the duties of a county medical officer of health, and Sir JOHN DICKSON-POYNDER succeeded in adding sub-clauses whereby the county medical officer of health cannot be appointed for a limited period; can only be removeable from office by, or with the consent of, the Local Government Board; cannot engage in private practice; and cannot hold any other public appointment without the consent of the Board. Three amendments to Clause 57, all having nearly the same end in view, were said to be outside the scope of the Bill. They were set down by Sir FRANCIS POWELL, Sir WALTER FOSTER, and Mr. WEDGWOOD. Sir FRANCIS POWELL'S amendment was to the effect that "no medical officer of health appointed under this or any other Act shall be removeable except by or with the sanction of the Local Government Board." Sir WALTER FOSTER'S amendment provided that a medical officer of health should not hold office for a limited period but should be liable to dismissal by the electing authority with the assent of the Local Government Board, and Mr. WEDGWOOD, in his amendment, limited this security against arbitrary dismissal to medical officers of health who were not in private practice.

It is a little difficult to understand how these amendments can be altogether outside the scope of the Bill. If district medical officers of health were not referred to in the Bill then amendments dealing with their appointments might very well be ruled as inadmissible. Such, however, is not by any means the case, for Sub-clauses (2) and (3) of Clause 58 require the medical officer of health of a district council, under a penalty of £10 for non-compliance, to give to the county medical officer of health any information which it is in his power to give and which may reasonably be required of him. This is the first instance in which it has been proposed that a district medical officer of health should be required to perform a particular duty for the non-performance of which a penalty has been proposed. There is every reason, therefore, for making the position of the district medical officer of health absolutely unassailable. The duties of the county officer are administrative and those of the district officer are executive, so that of the two the latter is the more likely to come into conflict with individual members of the electing body. We trust that at any rate one of the three amendments referred to will be introduced next session on the report stage of the Bill and that the President of the Local Government Board will be asked to state definitely what are his reasons for desiring to withhold from whole-time district medical officers of health the same security against unjust removal from office which he has so readily afforded to the county officials.

◆

The Law and Medical Practice by the Unqualified.

A PROSECUTION of an unusual character arising out of the use by R. S. ROSS, an unqualified person, of a title implying registration as a medical practitioner took place recently at Bishop Auckland. In cases of the usual class an unqualified person supplying treatment of a medical character—as the law, unfortunately for his patients, permits him to do—uses initials on his stationery implying medical degrees, or a brass plate upon his door which makes the same suggestion, or calls himself "Dr.," and so commits an offence for which he can be punished. Very frequently he is without medical training of any kind, and sometimes he has purchased for a small sum of money a bogus degree conferred by a foreign university, so-called, the uselessness of which might be recognised in the country of its origin but which in England helps the cunning quack to impose on the unwary. In the case referred to above the defendant, according to the story told on his behalf, was at one time a medical student and acted as assistant to a qualified medical practitioner. When the impropriety of such assistance became established and the at Madrid in 1903, when the Fourteenth International Congress of Medicine met in the Spanish capital. They witnessed with what exquisite courtesy and hospitality this vast assembly was received on two different occasions and entertained by the Queen Regent and the young King Alfonso in their magnificent palace and its extensive gardens. If there were not hotels enough to house the delegates there were plenty of palaces in which to receive them and State art tapestry to decorate the walls of the places where they met. Yet the Spaniards are a poverty-stricken people and Madrid is only a small city. But, of course, what was done in Spain was done by the Government, and there was no going round with a hat to get donations from millionaires whose interests are often diametrically opposed to the sanitary reforms which science claims on behalf of the public health. Therefore, it seems to me that the necessary preparations had not been made and the invitation given in 1905 for the Congress to meet in America in 1908 was premature.

To continue the narrative, I was quite seriously informed that the organising committee, after hunting round and visiting all the buildings in Washington, could not find any place that would be suitable for holding the Congress. This surely is a most astounding explanation, for obviously the resources of the capital of a great country must be well known. Since Washington as a city is still quite in its infancy its resources are naturally limited and therefore easy to ascertain and to enumerate. There could have been no difficulty in finding out beforehand, if it was not already known, whether there existed in Washington a suitable building available for the Congress. Yet it was only some time after Washington had been selected that it was discovered that the city possessed no place big enough for such a gathering. Then the organising committee bethought itself, not of the Capitol, that majestic building where both the Houses of Parliament meet, but of the Congressional Office Buildings. This adjacent building was found to be more suitable because it has a great number of private offices and large committee rooms where the sections might have met. Further, there are vast corridors that would have served very well for the exhibition which it was proposed to hold in connexion with the Congress. This, however, is a new building and was not yet completed. Some of the offices were finished and already occupied but others were still in the mason's or house decorator's hands and the corridors were far from ready. If, nevertheless, the International Congress on Tuberculosis had met there, the work would have been interrupted and could not be completed in time for the reassembly of the Senate and the House of Representatives.

In spite of these obstacles the organising committee of the International Congress on Tuberculosis pressed forward energetically a demand for the use of the Congressional Office Buildings. Then it was that Mr. James Mann of Illinois, member of Congress and one of the Whips of the Republican party, energetically opposed any such concession and was actively supported by the Speaker of the House, Mr. Cannon, and Mr. Payne, a member for New York, and others. Here I may perhaps explain that Mr. Joseph Gurney Cannon belongs to a Scotch-Irish Quaker family that took him across the mountains in a prairie schooner when he was four years old and that he has maintained himself since the age of 14 years. He has acquired a wonderful knowledge of the American political machine. "Uncle Joe," as he is familiarly called, has won great influence and popularity. Unfortunately, his surroundings and career were not those which would best fit him to appreciate the world's advance in medical science and the importance of extending international amenities to the representatives of learning and research. So Mr. Speaker Cannon refused to grant any facilities to the organisers of the Congress on Tuberculosis. He did not want the Congress buildings to be disarranged and feared that if he yielded other and less desirable requests would be made. Thereupon a regular campaign was organised. A great flood of letters poured in upon Congressmen of all parties. It is claimed that never before have Members of Parliament received so many protests and petitions. The medical profession throughout the United States set to work to bring this pressure to bear; and this is the specially cheering and encouraging aspect of the Washington Congress—namely, the energy and the whole-heartedness with which the general practitioners, the rank and file of the medical profession, threw themselves into the movement. These manifestations were so emphatic and widespread that now the great majority of the members of the two Houses were in favour of granting everything that was asked, no matter how great the derangement. However, the order of procedure is such that requests of this sort cannot receive assent rapidly unless they are made unanimously. Hence it suffices for one or two wreckers to object and the wishes of the majority are brushed aside. On this occasion again Mr. Mann and Mr. Cannon performed the part of principal wreckers.

The committee organising the International Congress on Tuberculosis now tried to obtain the Capitol itself, though it felt that it was not so well adapted for the purpose. Certainly it would have added great lustre to the plenary meetings had they been held in the Senatorial Chamber or the Hall of Representatives, and these Houses of Parliament are admirably suited for the purpose. On the other hand, there are no convenient rooms in the Capitol for the meetings of the sections. Then, again, it was intended for propaganda purposes to have an exhibition and to admit the public free of charge. The Capitol is still less suited for such a purpose. Rather than consent to this, many influential members of the legislature declared that they would prefer to vote a money grant so as to facilitate the holding of the Congress on Tuberculosis elsewhere. The committee, however, knew too well that there was no place elsewhere. Nevertheless, a Bill was brought in and £8000 were voted so that some other place might be rendered available. It was then decided to try to utilise the new National Museum which was in course of construction. The walls were up and the roof was on but that was about all. According to the law money voted in this manner should be spent under the direction of the President of the Republic. Mr. Roosevelt, it should be noted, had throughout supported all the requests made by the committee organising the Congress on Tuberculosis, but Mr. Mann and Mr. Cannon had between them the power to defeat the President's desires. As soon as the $40,000 had been voted the contractors building the new museum were stopped and special men were put in to work day and night, so that there might at least be some floors laid down before the members of the International Congress arrived. There was not time to spend the money granted to the best advantage. Money was lavished in hastening and paying for overtime that could have been devoted to secure better comfort and ornamentation if all this had been settled at an earlier date. Thus it was that when the Congress met the floors consisted of plain deal boards, unpolished, uncarpeted, and merely covered with sawdust which mingled unpleasantly with the atmosphere. Instead of various rooms and halls for the different sections there were but wooden palisades, terminated in the upper portions with cheesecloth, that constituted such slender partitions that the sounds travelled from one section to another. As shown in the accompanying reproduction of a photograph some of the windows had not yet been put in. The entrance was not constructed. There was only a gaping hole protected by a few rude planks and rough hoarding. By way of decoration two common planks had been nailed horizontally against two wooden posts and on them were painted the words "International Congress on Tuberculosis." For sole ornamentation there was a cluster of small, cheap, American flags; there were not even even a few flags of other nations.

To understand the effect that this rough makeshift produced it must be remembered that the previous International Congress on Tuberculosis had held its sittings in the Grand Palais of the Champs Elysées, a building so vast that the two rival French salons are able to hold their annual art exhibitions here at one and the same time. If we glance for one moment at the beautiful, the vast and imposing monumental entrance by which the members of the Congress passed every day to reach the sections from the Avenue d'Antin side of the Grand Palais, and compare that architectural *chef d'œuvre* with the shanty-like hoardings that masked the unfinished door of the Washington Museum, the deplorable effect this was likely to produce will be easily understood. But I am glad to be able by giving the history of how it all occurred to show that the fault was with the politicians and not with the medical profession. Undoubtedly it was highly imprudent for the American delegates at the Paris Congress of 1905 to offer American hospitality without having first assured themselves

NOVEMBER AT HOME AND ABROAD.

—	Highest temperature.	Lowest temperature.	Mean maximum temperature.	Mean minimum temperature.	Mean temperature for month.	Mean range of temperature.	Number of days with rain.	Total fall in month.

* A day with at least 0·04 inch.

Except for a few days round about the 10th and again for a short time about the 20th the weather over this country was very mild for the time of year, while, and this is very unusual with mildness in November, it was also much drier and brighter than the ordinary third month of autumn. In Italy, on the contrary, the temperature was rather lower than the normal, the wind often cold from the northward and north-eastward, and, as generally happens in that country after the long series of practically rainless and cloudless weeks during summer and early autumn, there was much rain. In the central countries of the continent and also in Belgium and the north-east and east of France the temperature was low for the time of year and frost of winter severity was rather frequent. The cold is strikingly shown by the mean temperature figures for the month at Berlin, Brussels, and Paris when compared with those in London and the other inland places in this country. Our metropolis was fully 10° warmer than Berlin and more than five and a half degrees warmer than Paris; while even Buxton, in spite of its altitude of nearly a thousand feet above the sea, enjoyed a mean *maximum* temperature almost as warm as that of Paris and a mean night temperature two degrees higher. Comparing the south-west coast of this country with some of the Mediterranean resorts it is seen that the Scilly Isles were milder than Nice, Florence, and Rome, and only slightly cooler than Genoa, while the night temperature, as shown by the mean minimum, was as high as that at Naples and Palermo. The nights at Torquay, Sandown, and Weymouth, although considerably cooler than at Scilly, were at least as mild as they were at Nice and Rome, and much milder than at Florence, while the mean minimum at the last-named city was identical with that at Harrogate. That Harrogate should have the same mean warmth during the nights of November as Florence is perhaps the most striking feature of the weather of last month. The Yorkshire resort is by no means noted for its mildness at night at any time of the year, and when there is any frost in that part of the country it is one of the first places to feel it. Algiers maintained its warmth with little diminution and its mean temperature of 66° was higher than that of any month of the summer in the south of England. Lisbon alone among the foreign stations experienced a temperature as equable as that on the south-west coast of England, but no place could compare with the isolated Scilly where the mean diurnal range was no more than six degrees.

HEROIC MEDICAL MISSIONARY.

THE *Sunday Strand* magazine for November prints an account of an interview with Dr. A. Macdonald Westwater, a medical missionary whose exploits during the last 27 years at Liaoyang have made his name a household word in Manchuria and earned him the admiration of Chinese, Japanese, and Russians no less than of his compatriot fellow-workers. He went first to China in 1881 as an agent of the United Presbyterian Church of Scotland, and after four years' work in the Shantung province he proceeded to Liaoyang, the ancient capital of Manchuria. Here he founded his mission in the face of bitter anti-foreign and anti-Christian feeling which often brought him into physical danger, and little progress was made until a severe flood devastated the district in 1888, when he gained the confidence of the people by superintending extensive relief works in a most able and energetic manner. At this time, too, his practice of western medicine began to bear its fruits and several high officials put themselves under his treatment. In the year 1895 the Chino-Japanese war broke out, during which Dr. Westwater retained the ground which he had won, although his colleague, the Rev. James Wylie, was murdered in the main street by Manchu soldiers. By 1900 his work seemed well established, but in that year the anti-foreign Boxer rising occurred and swept every missionary out of Manchuria. Hospitals, churches, and mission houses were burnt and a persecution of native Christians was instituted which resulted in many martyrdoms by murder and torture. Dr. Westwater and his family escaped to Japan, but he almost immediately took service under the Russian Red Cross and returned with the Russian repressive expedition to Manchuria. It was on this march that he earned his title of "the saviour of Liaoyang." The Russians had sacked and pillaged town after town, and on approaching Dr. Westwater's old station their advance guard was fired upon by some insurgents inside the town. To save "his people" from a terrible retaliation Dr. Westwater volunteered to ride unarmed and unattended into the town to arrange its prompt surrender under the Russian pledge of protection from reprisals. This he did and with complete success. Mr. Wigham, the war correspondent, described this action as "the bravest deed I ever saw," and anybody who considers the circumstances in which it was done can well credit his estimate of it. In Dr. Westwater's modest words, "They burnt my home and hospital and drove me and mine from the city. I return and save their homes from destruction and their lives from peril." The saving of Liaoyang by its would-be converter greatly helped on his missionary work and resulted in the building of a new hospital. But he had yet another time of terrible trial to go through during the Russo-Japanese war in 1904, during which for seven days a sharp fight was raging around Liaoyang. The town was expended large sums for this purpose. It is not fair to expect men of science to go round with the collecting hat. They thus expose themselves to insults and sometimes to very cruel and unjustifiable suspicions. Money collecting forms no part of a scientific education. Science demands to be placed high above the corrupting influences of money. Therefore the premises and money needed for these congresses should come from the State, and only from the State. The breath of scandal has never reached the many congresses which have been held under these conditions.

TUBERCULOSIS IN CANADA.

(By a Special Correspondent.)

North America is a large continent and in many respects there is a sharp line of demarcation between Canada and the United States, but in matters of education and in great social questions there are wonderful unanimity and cöordination. No sooner did we (the delegates from France, England, Scotland, and Ireland to the International Congress of Tuberculosis at Washington) land in Montreal than we found that a great wave had spread from Washington to the eastern side of Canadian territory, at any rate. The first Montreal newspaper that fell into our hands, after referring to the Washington Congress, gave some account of the prevalence of tuberculosis in Montreal and the Province of Quebec, and announced that the Association for the Prevention of Tuberculosis in Montreal was entering upon an extensive movement against this scourge, and that Dr. R. W. Philip of Edinburgh was to open the campaign by giving an account of his tuberculosis dispensary system as carried out in the capital of the North. I had the opportunity of attending this meeting which was held in the library of the Montreal Board of Trade. The meeting, which had been "convened" most carefully, was attended not by medical men only but by some of the most influential of the citizens, many of whom seemed to be impressed deeply by Dr. Philip's clear and concise statement of his case.

Professor J. G. Adami, in introducing Dr. Philip, spoke of the excellent work carried out in the capital of North Britain and suggested that what was possible in Edinburgh was possible also in a city like Montreal. He was glad to say that they had already made a beginning and that the Association for the Prevention of Tuberculosis had determined to hold an exhibition, to give lectures, and to train teachers and children in hygiene especially in its bearing on tuberculosis. Professor Adami, I learned afterwards, is chairman of the exhibition committee and is throwing himself with great energy and effect into the work of organisation of what promises to be a most successful movement.

Taking the "dispensary" as his starting point, but premising that this dispensary should be kept in closest touch with the medical officer of health's office, Dr. Philip made it clear that cases of tuberculosis could be sought out, sorted, educated, and treated by the dispensary officials more readily than by any other agents. The dispensary, in fact, was to be not only an information bureau but a clearing house. The patients who came for treatment could be kept under observation and other patients associated with them could be discovered. These could then be sorted into "lots," each of which should receive instruction and treatment suited to their special conditions and circumstances, and, if necessary, drafted to the hospital for the treatment of advanced cases, to the sanatorium for early cases, or receive such instruction as would render them more helpful to themselves and less dangerous to the community. Such, put very briefly, was the sketch placed before the business men of Montreal. In support of his thesis Dr. Philip gave a series of statistics bearing on the results obtained. Comparing Edinburgh and London and taking two periods of ten years each he showed how, as the outcome of the general measures taken to combat tuberculosis, there had been a steady and regular fall in both London and Edinburgh during the first ten years and that in London the fall had continued at the same steady rate during the second decade. In Edinburgh, however, during the second period, in which the dispensary organisation had been completed and brought into full operation, the fall had gone on much more rapidly and the death-rate from tuberculosis had fallen to a figure lower than that met with in almost any of the large towns in the country. Dr. Roddick, who occupied the chair, in thanking Dr. Philip, asked any of those present to put any difficulties which they might have before the lecturer who, he was sure, would be glad to answer any questions. Several other speakers called attention to the importance of this question to a large working community like Montreal. It was evident that tuberculosis was an infective disease, the infectivity extending over a very long period, though the results of infection might not manifest themselves for some considerable time. Still, if slow it was sure. Tuberculosis, however, though such a fatal disease was not only a curable disease if taken in its early stages but a preventable disease. If preventable why did they not prevent it? From the purely business point of view, it was well worth making an effort to eradicate a scourge which played such an important part in lowering the efficiency of their workers. Some questions put by members of the audience brought out the fact that many people would be glad to undertake their share of the work of the crusade if they could only make up their minds as to what they ought to do. Dr. Philip, in answering these questions, made it clear that the dispensary kept in close touch with the medical officer of health must be the centre of all the work, and that this should be made a first charge on any funds, corporate or private, which might be raised. The hospital for the treatment of advanced cases of pulmonary tuberculosis should be the special charge of the municipality, as this was the most important factor in "prevention." The sanatoriums or "curative" establishments might then be left to private liberality and the more such private liberality was exercised the sooner would preventive measures become less and less burdensome on the community.

It was very interesting to note how keenly the different statements were followed and with what applause the more practical parts of the address were punctuated by some of the shrewdest business men in the world, and I shall be much astonished if there is not some early and useful outcome of this significant meeting.

MANCHESTER.

(From our own Correspondent.)

Humane Slaughtering.

Many people who are not vegetarians feel some qualms when they think of the methods of slaughter adopted in killing animals intended for food. The pole-axe and pithing are the means chiefly used in these northern parts, but a demonstration was given on Nov. 25th of a method that may be called new here, though it is used more or less in some of the southern districts. It consists of a short revolver barrel ending in a square-shaped extension which enables the operator to put the instrument in the correct position. This is connected with a shaft at right angles to it, down the centre of which runs a wire to a hole at the end. The barrel being placed on the forehead, the bulleted cartridge, ·450 smokeless, fired by the wire trigger at the end of the shaft, makes a hole in the animal's head large enough to admit of the insertion of a cane for pithing purposes. An official of the Royal Society for the Prevention of Cruelty to Animals gave a demonstration of the effectiveness of the instrument and those present expressed approval of the great humanity of the method. In no case was more than a slight convulsion observed in the fallen animal which was killed instantly.

Workhouse Beer.

There is no uniformity in this district in regard to allowing the inmates of the workhouses beer at Christmas. In Salford this vexed question has been settled, in a kind of "split the difference" way, by the officers having a barrel of beer brought in for use at Christmas while the pauper inmates are to have none. The conscience of the guardians will therefore be clear as far as the paupers are concerned. One of the guardians was so imbued with logic that he thought if beer was bad for the inmates it was also bad for the officers. Another said that the workhouse committee without comment agreed as to the officers but that there was a storm when beer was suggested for the inmates. Another guardian said that he "was not against beer" but it was not reasonable to treat the officers and inmates alike in this matter.

celebrate its first annual dinner. He hoped that the society might long continue to maintain the dignity, the honour, and the tradition of the great medical profession. The Chairman, in responding, said that the society now numbered 2215 Fellows and 959 Members and their library comprised over 100,000 volumes. There were certain special branches of medicine as yet unrepresented in the society, but he trusted they would be embraced before long in that body. They were not the *Royal Society of Medicine of London* but of the British Empire. Of their Fellows and Members there were 1780 in London, 1174 in the provinces, and 220 were scattered over the face of the world. He hoped that the day would come when the connexion between their society and the representative bodies in the provinces and throughout the British Empire might become closer than it was at the present time. In the course of his speech the Chairman acknowledged the services rendered to the society by the secretary, Mr. MacAlister, and the assistant secretary, Dr. Nachbar. The toast of "The Guests" was submitted by Dr. F. Taylor who mentioned the fact that one of the guests was Mr. Lockwood, the President of the Medical Society of London, which was one of the senior societies possessing house property and holding money in the funds, which society they would be glad to amalgamate with the Royal Society of Medicine. This toast was replied to by Mr. Justice Darling and Sir E. Henry, after which the health of the chairman was given by Sir R. Douglas Powell and was duly acknowledged.

PIERRE L'ANGLOIS.

UPON several occasions THE LANCET has referred to the erudition and extraordinary knowledge of science and history possessed by the celebrated Dr. Young who, as is well known, was, with the French *savant* Champollion, the first successfully to unravel some of the secrets of the Egyptian hieroglyphic writing. Champollion having continued his researches longer than Dr. Young carried the matter much further and has received more of the fame. It now appears that another medical man so long ago as 1583 attempted to decipher the meaning of the hieroglyphics, and as he was a Frenchman our *confrères* across the Channel will consider that France holds the premier place in the history of the studying of the secret of the writing—unless the suggestion is made that a man with such a name as L'Anglois must have been an Englishman. For the name of this new candidate for honours in the matter was Pierre L'Anglois, Sieur de Bel-Estat, and he was attached as physician to the Duc d'Anjou, who became king in 1574 as Henri III. L'Anglois was not, however, only concerned in medicine but cultivated poetry and took an especial interest in heraldry. His researches into the armorial bearings or achievements of France and Italy led him to endeavour to prove the origin of some of the emblazons from Egyptian hieroglyphs, and finally he published two works on the subject, "Discours des Hieroglyphs *Aegyptiens, Emblems, Devises, et Armoiries*" and "LIV. Tableaux Hieroglyphiques pour exprimer toutes Conceptions à la Façon des Egyptiens, par Figures et Images des Choses, au lieu de Lettres. Avec Plusieurs Interpretations des Sanges et Prodigues." As with many medical men, he appears to have derived amusement and relaxation from continuing the reading of the classics, for he appends a list of those which he utilised in the execution of his books. This comprises over 30, among which are Aristotle, the Bible, Herodotus, and Erasmus, and it would, if space permitted, be interesting to append this catalogue of a physician's library in France in the sixteenth century. If the question is asked whether his researches into Egyptian matters were of any value and deserve rescue from oblivion in the cause of science the answer must be in the negative. He, however, went the best way to work possible in Europe at his age, consulting such authors as Horus Apollo who wrote specially on the hieroglyphs; Clement of Alexandria who says a good deal about them in his monograph on Egyptian religion; Atheneaus who being a native of Naucratis knew something of the matter; and Porphyry. His book of hieroglyphical emblems is very curious because of the out-of-the-way mediæval lore and strange suggestions which he makes concerning them. He commences with the lion, then proceeds to the elephant, an animal that does not appear as a hieroglyph, so far as is yet known, until about the time of Alexander, but was used frequently on Roman coins, as drawing in various numbers, sometimes four, the Imperial Chariot at triumphs. The bull and the horse follow, and then comes a variety of weapons and utensils and other objects. In future works on the search for the secrets of the hieroglyghs the efforts of L'Anglois will always deserve a brief mention, and in any enumeration of medical men who endeavoured, even if not successfully, to advance the cause of science he also should find a niche. His medical knowledge evidently prevented him from branching off into the astrology and quackery which the charlatans of his time always connected with a pretended knowledge of Egyptian writing, and it is probable that he was, in a true sense, a scholar.

THE METROPOLITAN WATER-SUPPLY: SECOND REPORT ON RESEARCH WORK.

AT a meeting of the Metropolitan Water Board on Dec. 4th Dr. A. C. Houston presented his second report on research work made during the 12 months ending July 31st last. It proves that during the past year his laboratory has been occupied by an investigation no less arduous if less conclusive than that embodied in his first report. It will be remembered that therein he described experiments proving that the simple storage of water is an efficient means of freeing it from a very large percentage of typhoid bacilli introduced artificially. The present research was undertaken to discover if the typhoid bacillus could be detected in *raw* Thames, Lea, and New River water, which supply nearly the whole of the water under the control of the Metropolitan Board, and the result was negative. The report begins by laying stress upon the significance of bacillus coli contamination in water as pointing to the possibility of typhoid contamination and upon the necessity of interpreting bacteriological findings in the light of local conditions, a point on which we have often laid stress. Our readers are also well aware by this time that the raw London waters are practically diluted sewage, but the truth of this is shown so clearly in a table in the report that we reproduce a part of it. It shows the percentage number of samples in which typical bacillus coli was found during the 12 months ending March, 1908, in the raw London waters.

—	Negative.	Positive in 1 c.c. or in smaller samples.	Positive in 0·1 c.c. or in smaller samples.
Raw Thames water at Hampton Court ...	16·8	83·2	46·8
Raw Lea water at Ponder's End	9·2	90·8	46·8
New River water at Hornsey	50·4	49·6	14·4

The raw Lea water was so bad that 10·4 per cent. of 0·01 cubic centimetre samples and 2·4 per cent. of 0·001 cubic centimetre samples gave growths of bacillus coli. Although this that the experience of the last 25 years indicates that the public health enactments as regards the stamping out of acute infectious diseases have not been so successful as was anticipated, and that modifications in the way of lessened legislative interference in the ordinary relations between medical man and patient were desirable; (2) that the compulsory notification of phthisis as an infectious disease should be ordained in those cases only in which, in the judgment of the medical practitioner, the patient's condition and surroundings form a menace to the public health; and (3) that in the better-class schools any medical inspection of the pupils required by the State should be carried out by the family medical attendant or by the medical man ordinarily employed by the parents or guardians of the pupils. The measure of interest taken in these propositions may be gauged by the fact that the members of the association discussed them at three meetings. Many members spoke and, as might be expected, there were different views; the quality of the speaking was good on the whole. The debate concluded on Saturday night, Dec. 5th. In concluding a debate of the kind and in procuring definite and clear findings from such a meeting the tax thrown upon the chairman is great, and unless he is an experienced man of affairs there are liable to be confusion and some display of temper from members. The concluding night was not without such indications. It was understood, however, that the motions mentioned above were carried by a majority of the members present. The future action or inaction of this new association will be watched with much interest—it is essentially a practitioners' association and has been taken up warmly and almost unanimously by the medical men in Edinburgh and Leith and the capacity of the practitioner for wise and combined action is on its trial. Probably in no place could such an association have more favourable conditions in which to develop satisfactorily than Edinburgh and Leith provide. On Saturday, Dec. 12th, the association is to have a smoking concert.

The End of the First Term of the Winter Session.

Many old students of the University of Edinburgh will be interested to know that the division of the winter session into two terms takes practical effect this winter. The first term ended on Wednesday, Dec. 9th, and the second term will not begin until Tuesday, Jan. 5th. Professional examinations are held during the first part of the Christmas vacation, in accordance with the new regulations.

Royal Medical Society of Edinburgh.

At Melbourne Place, Edinburgh, on Nov. 27th, Mr. J. G. Nicholson read a paper on "Alcoholism and Drug Habits." The drugs dealt with in the course of a very interesting paper were alcohol, opium, cocaine, ether, chloroform, and tobacco. Dr. Laurance described four cases of labour complicated by flat pelves, and detailed the treatment which had been adopted in each case. Cæsarean section was successfully adopted in one case; the remainder had of necessity to be treated by other methods, and in none of these was the child saved.

Medical Inspection and Cleanliness in Schools.

At a recent meeting of the Glasgow and West of Scotland Mistresses' Association an interesting discussion took place regarding medical examination of scholars as viewed from the teacher's standpoint. Those members of the association who had had experience of medical inspection gave it as their opinion that, as conducted at present, it was unsatisfactory. It involved for the time being considerable disorganisation of the work of the school, laid a heavy burden of clerical work on the teacher, and the results were practically *nil*. Very little attention was paid by the parents to the medical man's recommendations, and as there is no power of compelling such attention the elaborate health schedules simply resolve themselves into a supply of statistics. It had been hoped by those concerned that the medical inspection would have been an aid in the direction of cleanliness. Unfortunately it had had no such effect. Further discussion showed that the visits to schools by women sanitary inspectors were of considerable value as a check on excessively filthy conditions, but there was a normal state of untidiness and dirt found amongst poor children which it was agreed was unnecessary and due to carelessness and laziness and to the tacit acceptance by the general public of dirt as synonymous with poverty.

Glasgow Western Infirmary.

At the annual meeting of the supporters of the Glasgow Western Infirmary held last week attention was drawn to the fact that there was an increasing demand for hospital accommodation, there being 500 patients awaiting admission. It has been possible during the year to meet the ordinary expenditure without encroaching on invested funds, but that has been possible only because the extraordinary income—which must always be a precarious source of revenue—has been much above the average. It is fortunate, also, that during a year of commercial depression the ordinary income has not decreased. Still, as long as it is nearly £15,000 short of the ordinary expenditure it is obvious that the financial position is unsatisfactory. Plans have been prepared for a further extension of the infirmary but the directors have not at present enough money in hand to proceed with it. In the meantime, however, an addition is being made to the nurses' homes which, while needed at present, will also prove sufficient for the requirements of the further extension of the infirmary.

Braemar Parish Council: Appointment of Medical Officer.

The half-yearly meeting of the Crathie and Braemar parish council was held on Dec. 2nd at Braemar. The committee appointed to secure a medical officer for the parish handed in its report. It recommended that Dr. Forsyth, a graduate of the University of Edinburgh, who was now resident in the village, should be appointed. This was ultimately agreed to by 6 votes to 2.

Dundee Asylum Farm.

At a meeting of the Dundee district lunacy board held on Dec. 2nd the farm committee reported that Captain Clayhills Henderson, of Invergowrie, R.N., had offered a new lease of Whitebaston Farm for 22 years at the present rent of £300. He would contribute £300 towards alterations and renewals, provided the board paid him an extra annual sum of £15 and that any further expenditure above £300 would be paid by the board. It was resolved to accept the offer.

Death of Dr. William Paterson of Inverurie.

Dr. William Paterson died at his residence, Ardennan, Port Elphinstone, on Nov. 26th. He retired from active practice about six years ago and had been in weak health for some time. Born in 1842, Dr. Paterson after a brilliant career at the University of Aberdeen graduated M.B., C.M. at the early age of 21 years and afterwards obtained his M.D. degree. He went to Inverurie in 1864 as assistant to the late Dr. Thomas Thomson and ultimately succeeded to his practice. Dr. Paterson held numerous local appointments and was a keen Volunteer and musician. For a number of years he acted as President of the Inverurie Musical Association, and at the time of his death was president of the Inverurie and Garioch Savings Bank.

Dec. 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Itinerant Instruction in Ireland.

IN the present transition stage of education in Ireland—general, university, scientific and sanitary—the appreciation which itinerant instruction has received in the report of the county of Galway (joint) technical instruction committee to the Galway Council and Ballinasloe Urban Council possesses a special and very important interest. In the opinion of that committee it holds the field against all competitors. "No feasible alternative system has yet been proposed by which the advantages of instruction in cookery, laundry work, needlework, *hygiene, sick nursing*, and manual work can be given to so great a number of persons, over so large an area, and under the conditions which prevail in this country." And an emphatic compliment is paid to the committee in the report of the department's inspector on the working of the scheme in the county of Galway: "The lecturer in hygiene gave short courses of instruction on the essentials of a healthy existence, the prevention of consumption, and the care of the sick at nine selected centres. The work was facilitated by the clergy and teachers of the county and has done much to alleviate suffering and make the homes of the poor more inviting resting-places." There is evidence attributed to efficient inspection and control of midwives within the county and to the indirect and instructional influence thus brought to bear upon mothers resulting in the more judicious treatment of young infants.

THE DWELLINGS OF THE POOR.

THE report of the Mansion House Council on the Dwellings of the Poor for the year ending June, 1908, states that the total number of inspections made during the 12 months covered by the report was 2642, dealing with 1415 houses. The remedied cases were 459. A notable feature of the report is the statement that the activity of health societies in London is steadily increasing and that the existing societies, which are adding to their numbers, have formed a central representative council to consider (1) the possibility of securing some uniform method for the notification of phthisis by the London hospitals and dispensaries; and (2) how to secure the best results for the provisions of the Education Act, 1907, as to medical inspection of children in elementary schools. With the object of assisting the health societies in this matter the executive committee of the council has appointed Dr. A. H. Hogarth and Dr. C. Singer to help the health societies in the realisation of their programme. It is regrettable that a society which does such good work should be hampered by want of funds. The subscriptions for 1907-08 amounted to only £133, while £800 a year is necessary to enable the council to carry out fully the objects for which it exists and for which it has worked for 24 years. To meet liabilities the council has had to sell out the remaining £350 of a legacy of £1000 which it received under the will of the late Miss Flora Goldsmid. The offices of the council, of which the Lord Mayor is President, are at 31, Imperial-buildings, Ludgate-circus, E.C. The Union of London and Smith's Bank, Limited, are the bankers. Any influence which medical men may have to direct subscriptions has now so many legitimate directions that it seems idle to suggest another, but the Mansion House Council on the Dwellings of the Poor does a splendid work with a distinct medical bearing.

A SHAKESPEARE COMMEMORATION FOR LONDON.

WE have received from Dr. R. W. Leftwich an abridged form of an article bearing the above heading which appeared in the *Westminster Review* for June. In it Dr. Leftwich pleads for some commemoration ceremony to be held in London as a means of emphasising Shakespeare's connexion with the City. We learn that it has been decided by the Chapter of Southwark Cathedral to hold a Shakespeare Commemoration service on April 23rd. The choice of day is peculiarly fitting, for it is, as every Englishman should know, St. George's Day, and if ever there was a poet who thought imperially it was Shakespeare. Moreover, on that date Shakespeare died and it, or April 22nd, was his birthday. Nor is the building less fitting the occasion. Southwark Cathedral, formerly St. Marie Overie, is close to the site of the old Globe Theatre which belonged in part to Shakespeare. In the church are buried Gower, Dyer, Fletcher, and Massinger. From our own point of view the old priory of St. Marie Overie is of interest, for it was served by Augustinian canons, which body also served the great hospital and priory of St. Bartholomew. Shakespeare, too, showed a wonderful knowledge of medicine and surgery, a point which was well brought out quite recently in a book, "The Medical and Surgical Knowledge of William Shakespeare," by Dr. John W. Wainwright, reviewed in these columns on April 18th. We gather that it is owing to Dr. Leftwich's suggestion that the determination to hold the service has been taken and we see that he is the honorary secretary of the movement. May we be permitted to suggest that the music used at the service shall, so far as is possible, be that of about Shakespeare's time? The music of the reign of Elizabeth and her successor was the golden age of English music, and one of the most beautiful anthems of the sixteenth century is attributed to Henry VIII. If the service is held in the evening no more fitting anthem could be used than this.

WHAT IS CHAMPAGNE?

STEPS have recently been taken, it is reported, to restrict the application of the word "champagne" to wines produced in certain districts. It is stated that wines have been imported into these districts and kept there for a while and then sent out marked as genuine champagne wine, a practice which was obviously unfair to the Champagne growers. The districts include the greater part of the Marne, as well as Chateau Thierry and Soissons. The movement, we think, is a right one, and we should like to see the principle of it extended to other wine-producing departments. At the same time, the fact need not be overlooked that champagne is not the only excellent and wholesome sparkling wine produced in France. Quite good sparkling wines are made in Saumur and in the Medoc district, and there is nothing to be said against them so long as they are honestly described.

THE CHEMICAL COMPOSITION OF HUMAN TEETH COMPARED WITH THOSE OF THE DOG.

THAT the teeth of animals offer a greater resistance to pathological influences than is the case with human teeth is a generally accepted fact for which various causes have been assigned. The length of life of the individual must necessarily be considered in making a comparison, for it is obvious that the teeth of a full-grown person have been subjected to destructive influences for about 20 years more than those of a full-grown dog. The nature of the food also plays an important part. Some further light has been thrown on the subject by M. Th. Gassmann, who has made a chemical analysis of human and dogs' teeth in order to ascertain whether there is any considerable difference in their composition. The results (which are recorded in the *Zeitschrift für Physiologische Chemie*, 1908, vol. lv., p. 455) are given in percentages in the following table.

—	Human teeth.				Dogs' teeth.
	Canines.	Milk teeth.	Third molars.	Teeth of aged persons.	
Water	8·09	3·76	6·91	8·17	10·97
Loss on calcination	22·20	22·84	18·33	21·42	25·99
Lime	29·78	29·59	31·65	30·25	27·33

These figures show that human teeth contain more lime than those of the dog, and the third molars which are richest in lime, contain nearly 5 per cent. more than is present in dogs' teeth. The loss due to calcination affords an approximate indication of the amount of organic matter present. It will be noticed that whereas dogs' teeth are the richest in organic matter human third molars are poorest in that respect. The quantity of phosphoric acid is proportional to the lime present. Human teeth are richest in chlorine and the salts of potassium, whereas in dogs' teeth the salts of sodium predominate. It is noteworthy that the third molars, which are the most prone to decay, are relatively rich in lime and poor in organic matter. M. Gassmann draws combined with general treatment, but in chronic cases its utility was doubtful.

A New Clinic.

Dr. Huchard, the well-known physician to the Necker Hospital and a specialist in diseases of the heart, is just about to resign his post at the hospital owing to the age limit. He recently opened a clinic in the Vaugirard quarter and the official opening took place on Nov. 17th in the presence of many pupils and friends. A number of patients attended on the first day, when M. Huchard said that the opening of the clinic would fill a gap, for hitherto no clinic for diseases of the heart was to be found. M. Albert Robin, who followed, took occasion to congratulate M. Huchard on his new departure.

Treatment of Cancer by Injections of Formol.

At a meeting of the Academy of Medicine held on Nov. 24th M. Laurent stated that after researches extending over many years he had come to the conclusion that a very good method of treatment for malignant tumours was to "formalise" them by enormous doses of formol by injection. The dose varied from 5 to 60 grammes. Part of the tumour sloughs and the remainder undergoes absorption, thanks to the reaction set up by the drug. The method requires caution in its use and external growths alone are suitable for its employment. Moreover, the patients should not be too run down or they will not be able to stand the somewhat violent reaction which occurs.

The Treatment of Hæmorrhage by Subcutaneous Injection of Gelatin.

At a meeting of the Hospitals Medical Society held on Nov. 20th M. Chaput gave an account of some results which he had obtained in the treatment of secondary hæmorrhage by injections of gelatin, as advised by Carnot. In one case, that of a patient operated upon for uterine fibroma, and in whom hæmorrhage occurred owing to a ligature slipping, M. Chaput was easily able to gain command of the hæmorrhage by the use of gelatin. In another patient who had undergone total hysterectomy the operation had left sundry oozing surfaces, the hæmorrhage from which could not be arrested until recourse was had to injections of gelatin. He cited three similar cases in which the gelatin had had the same effect. In cases of secondary hæmorrhage, instead of following the usual course of opening up the wound at once, M. Chaput advises the use of a subcutaneous injection of gelatin and the hæmorrhage will stop and further steps can be taken later with a much greater chance of success than by following the ordinary method. Blood, of which the ordinary coagulation period is seven minutes, clots in three minutes after an injection of gelatin; the dose is about 5 grammes of gelatin in a 1 per cent. solution. The method is very useful in cases of ruptured tubal pregnancy.

Medical Treatment of Pelvic Disorders.

At a meeting of the Academy of Medicine held on Nov. 24th M. Richelot referred to the charge which is so often made against the medical profession of having recourse to surgical intervention in cases of pelvic affection without trying medical therapeutic measures first. He laid stress upon the harmful effects which this method of procedure may have in women, especially when they are young. In some cases of pelvic infection where operation would seem to be necessary there may be even greater reasons for non-interference. In patients of the "neuro-arthritic" type who suffer from uterine congestion, dysmenorrhœa, or hæmorrhage, both physicians and surgeons are often much troubled as to treatment. There are, however, everyday methods of medical treatment out of which neither patients nor practitioners get the full benefit. Take, for instance, the use of hot water; not half enough stress is laid upon the quantity used, the necessity for a high temperature, and the manner of use. As for the external douche, it would seem to be reserved entirely for neurologists and that the gynæcologists have doubts as to its utility. There are two main methods of applying hot water, the one being the vaginal douche and the other the external douche. To obtain the best results from the former from 80 to 100 litres should be used, and the external douche should be employed under the two forms of a general douche and a perigastric douche. This practically necessitates the use of special apparatus.

Dec. 8th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Experiments on Artificial Abortion.

BEFORE the Berlin Gynæcological Society Dr. Hofbauer read a paper on Artificial Abortion produced by the Administration of Cholesterin. The experiments, which were made by Dr. Hofbauer on pregnant rabbits, were based on the existence of a physiological antagonism between cholesterin and lecithin and on the grounds that the cells of the fœtus contain a great quantity of lecithin and chemical alterations of the lecithin are harmful for the development of the fœtus. Cholesterin, the antagonist to lecithin, was administered to pregnant rabbits in the form of a 5 per cent. solution and given together with the ordinary food. It had been stated previously by other authors that cholesterin given by the mouth is absorbed fairly easily and is later found in the blood plasma. The experiments were made on three pregnant rabbits. In the first an animal in the middle of its pregnancy was employed; 10 cubic centimetres of cholesterin were given three times a day, the result being that the animal was delivered of two dead fœtuses on the fourth day. Necropsy showed that the cellular tissue had a brownish-red hue just as in a macerated fœtus and that the pleura also was ulcerated in certain places. The second animal was nearly at full term and cholesterin was administered in the same way as in the first case. Since by the eighth day no delivery had taken place the uterus was opened under narcosis and three fœtuses were found, of which one was dead. The skin of this fœtus proved to be flaccid, the cellular tissue was blood-stained, and the internal organs had a pale greyish-red colour. The placenta of the dead fœtus was of greyish-yellow colour and of an abnormally solid texture; it was dry and smaller than that of the other fœtuses. No structure was visible in the placenta save in the centre, its substance being very homogeneous and opaque with yellow spots scattered about in it. On microscopical examination the tissue proved to be full of cells, so that it almost looked like granulation tissue instead of the characteristic placental tissue; the vessels were empty and showed a proliferation of the intima. In some parts the tissue had become a structureless mass with streaks of fibrin and cellular tissue and small hæmorrhages. The third animal was also nearly at full term. On the fourth day after treatment three dead fœtuses were removed by Cæsarean section and showed similar changes, but in a higher degree than in the second experiment. It follows from the above experiments that by the administration of cholesterin severe degenerative changes were produced in the placenta which seriously affected its function, and it is probable that these changes were due to a destruction of the lecithin. Dr. Hofbauer suggested that the maceration of the fœtus in syphilis may be proved to have a similar cause—viz., the destruction of lecithin by the serum of the syphilitic mother. He alluded to the researches of Professor Wassermann who found in syphilitic serum toxic substances by which lecithin can be decomposed.

A Question of Medical Ethics.

As already mentioned in these columns the Union of the German Medical Press has taken energetic measures against authors who write articles to recommend new chemical compounds and other preparations in trade interests. Some of these authors are alleged to report cures in cases which as a matter of fact have never existed, and lately a medical journal exposed one of these authors by publishing two articles which he had written within three months of each other and which were couched in almost the same terms. In these he had cited the same cases in recommendation of two different compounds. But some German chemical factories not only employ certain medical men to write puff articles for them, they also quite correctly approach the directors of medical clinics and institutions, asking them to give a fair trial to certain new compounds. As they used to offer fees for the researches made in the clinics and laboratories the question was put whether it would be in accordance with the rules of medical ethics to accept such fees. The editor of the *Deutsche Medizinische Wochenschrift* has recently made a collective investigation by asking the opinion of chief physicians of hospitals and directors of medical clinics and institutions on this matter. The questions asked were: Did attributed to efficient inspection and control of midwives within the county and to the indirect and instructional influence thus brought to bear upon mothers resulting in the more judicious treatment of young infants.

THE DWELLINGS OF THE POOR.

THE report of the Mansion House Council on the Dwellings of the Poor for the year ending June, 1908, states that the total number of inspections made during the 12 months covered by the report was 2642, dealing with 1415 houses. The remedied cases were 459. A notable feature of the report is the statement that the activity of health societies in London is steadily increasing and that the existing societies, which are adding to their numbers, have formed a central representative council to consider (1) the possibility of securing some uniform method for the notification of phthisis by the London hospitals and dispensaries; and (2) how to secure the best results for the provisions of the Education Act, 1907, as to medical inspection of children in elementary schools. With the object of assisting the health societies in this matter the executive committee of the council has appointed Dr. A. H. Hogarth and Dr. C. Singer to help the health societies in the realisation of their programme. It is regrettable that a society which does such good work should be hampered by want of funds. The subscriptions for 1907–08 amounted to only £133, while £800 a year is necessary to enable the council to carry out fully the objects for which it exists and for which it has worked for 24 years. To meet liabilities the council has had to sell out the remaining £350 of a legacy of £1000 which it received under the will of the late Miss Flora Goldsmid. The offices of the council, of which the Lord Mayor is President, are at 31, Imperial-buildings, Ludgate-circus, E.C. The Union of London and Smith's Bank, Limited, are the bankers. Any influence which medical men may have to direct subscriptions has now so many legitimate directions that it seems idle to suggest another, but the Mansion House Council on the Dwellings of the Poor does a splendid work with a distinct medical bearing.

A SHAKESPEARE COMMEMORATION FOR LONDON.

WE have received from Dr. R. W. Leftwich an abridged form of an article bearing the above heading which appeared in the *Westminster Review* for June. In it Dr. Leftwich pleads for some commemoration ceremony to be held in London as a means of emphasising Shakespeare's connexion with the City. We learn that it has been decided by the Chapter of Southwark Cathedral to hold a Shakespeare Commemoration service on April 23rd. The choice of day is peculiarly fitting, for it is, as every Englishman should know, St. George's Day, and if ever there was a poet who thought imperially it was Shakespeare. Moreover, on that date Shakespeare died and it, or April 22nd, was his birthday. Nor is the building less fitting the occasion. Southwark Cathedral, formerly St. Marie Overie, is close to the site of the old Globe Theatre which belonged in part to Shakespeare. In the church are buried Gower, Dyer, Fletcher, and Massinger. From our own point of view the old priory of St. Marie Overie is of interest, for it was served by Augustinian canons, which body also served the great hospital and priory of St. Bartholomew. Shakespeare, too, showed a wonderful knowledge of medicine and surgery, a point which was well brought out quite recently in a book, "The Medical and Surgical Knowledge of William Shakespeare," by Dr. John W. Wainwright, reviewed in these columns on April 18th. We gather that it is owing to Dr. Leftwich's suggestion that the determination to hold the service has been taken and we see that he is the honorary secretary of the movement. May we be permitted to suggest that the music used at the service shall, so far as is possible, be that of about Shakespeare's time? The music of the reign of Elizabeth and her successor was the golden age of English music, and one of the most beautiful anthems of the sixteenth century is attributed to Henry VIII. If the service is held in the evening no more fitting anthem could be used than this.

WHAT IS CHAMPAGNE?

STEPS have recently been taken, it is reported, to restrict the application of the word "champagne" to wines *produced* in certain districts. It is stated that wines have been imported into these districts and kept there for a while and then sent out marked as genuine champagne wine, a practice which was obviously unfair to the Champagne growers. The districts include the greater part of the Marne, as well as Chateau Thierry and Soissons. The movement, we think, is a right one, and we should like to see the principle of it extended to other wine-producing departments. At the same time, the fact need not be overlooked that champagne is not the only excellent and wholesome sparkling wine produced in France. Quite good sparkling wines are made in Saumur and in the Medoc district, and there is nothing to be said against them so long as they are honestly described.

THE CHEMICAL COMPOSITION OF HUMAN TEETH COMPARED WITH THOSE OF THE DOG.

THAT the teeth of animals offer a greater resistance to pathological influences than is the case with human teeth is a generally accepted fact for which various causes have been assigned. The length of life of the individual must necessarily be considered in making a comparison, for it is obvious that the teeth of a full-grown person have been subjected to destructive influences for about 20 years more than those of a full-grown dog. The nature of the food also plays an important part. Some further light has been thrown on the subject by M. Th. Gassmann, who has made a chemical analysis of human and dogs' teeth in order to ascertain whether there is any considerable difference in their composition. The results (which are recorded in the *Zeitschrift für Physiologische Chemie*, 1908, vol. lv., p. 455) are given in percentages in the following table.

—	Human teeth.				Dogs' teeth.
	Canines.	Milk teeth.	Third molars.	Teeth of aged persons.	
Water	8·09	3·76	6·91	8·17	10·97
Loss on calcination	22·20	22·84	13·33	21·42	25·99
Lime	29·73	29·59	31·65	30·25	27·33

These figures show that human teeth contain more lime than those of the dog, and the third molars which are richest in lime, contain nearly 5 per cent. more than is present in dogs' teeth. The loss due to calcination affords an approximate indication of the amount of organic matter present. It will be noticed that whereas dogs' teeth are the richest in organic matter human third molars are poorest in that respect. The quantity of phosphoric acid is proportional to the lime present. Human teeth are richest in chlorine and the salts of potassium, whereas in dogs' teeth the salts of sodium predominate. It is noteworthy that the *third* molars, which are the most prone to decay, are relatively rich in lime and poor in organic matter. M. Gassmann draws reached the age limit. He will be succeeded by Colonel George H. Torney, one of the most efficient officers of the army, who will have upwards of five years of service before retiring on account of age. He has had a long and brilliant career in the army. During the Spanish-American war he prepared for active service the hospital ship *Relief* and commanded her on the removal of the sick and wounded from Cuba and Porto Rico. He was placed in charge of the sanitary work at San Francisco on the occurrence of the earthquake which destroyed that city and was highly commended by the authorities for his efficiency and his success in managing the details of the work of sanitation. The annual report of the Surgeon-General shows that the death-rate from all causes was 5·81 per 1000 of a mean strength of 54,949. The most important among the causes of death were tuberculosis with a ratio per 1000 of 53; pneumonia, 44; cerebro-spinal fever, 38; enteric fever, 29; and heart diseases, 27. These rates are higher than for the preceding year, except tuberculosis, which is considerably lower. The most important disease affecting the efficiency of the army was the venereal, the admission rate being 196·62 per 1000.

Laws against the Marriage of Epileptics.

There is much agitation in favour of prohibiting the marriage of epileptics by legislation and in several States laws have been passed to that effect but they do not accomplish the results sought. The latest report is from the State of Kansas which passed such a law many years ago. Dr. Perry, superintendent of the State Hospital for Epileptics, finds that 30 per cent. of the male epileptics over 21 years of age are married and 25 per cent. were married after the disease was developed. Of the female epileptics over 18 years of age 56·8 per cent. were married and 40 per cent. had married since they became epileptic. These facts prove that the law is practically ignored by officials. It is urged in defence of clergymen that there are large numbers of cases in whom the disease assumes such forms that even the friends of the epileptic and the epileptic himself may not be aware of the occurrence of seizures. Dr. Perry recommends that a penalty should be attached to failure on the part of a licensed official to investigate each case in which he performs the ceremony of marriage.

Responsibility for Death by Chloroform Unnecessarily Administered.

The United States Circuit Court, in New York, had a case where an employee sustained one of the simplest and least complicated forms of dislocation at the shoulder-joint, but the patient died from the effects of the chloroform administered for its reduction. The company which employed the patient was not held liable for the death, the jury having found that the accident and injury (dislocation caused by the accident) had nothing to do with causing or producing the death, but that the subsequent unnecessary administration of chloroform caused it. The court held that the surgeons and attendants in a hospital are not immune from the charge of being the third person causing death, and not immune from the charge of causing the death of the patient therein by their own independent and wrongful acts, even if connected with a necessary operation. If they are, then they may experiment with and on every patient and unnecessarily give dangerous drugs and unnecessarily perform dangerous operations, and if such drugs and operations, so unnecessarily given or performed, kill, and are the sole cause of death, then the persons whose negligence caused a slight injury, requiring some slight operation, must answer for the consequences of such experiments and operations and respond in damages for the death on the ground that their negligent act set the surgeons and attendants in motion or gave them an opportunity to experiment with death-dealing instrumentalities. In legal contemplation, negligent parties must be responsible for injury, necessary medical treatment, or surgical operations, and mere errors of the physicians and surgeons in doing necessary things, as all these are natural and probable results, happenings; but the court knows of no holding that unnecessary treatment with dangerous drugs, which the jury found this was, is either the natural or probable consequence of injury.

Leprosy-like Disease of Rats in San Francisco.

The campaign against rats to relieve San Francisco of the bubonic plague has revealed the presence of a considerable proportion of rats affected with leprosy, or a disease closely resembling that form of plague. These rats were found in greatest numbers in that part of the city occupied by the butcher shops and meat-packing establishments. None of the infected animals came from stables and warehouses where the rats infected with the plague are more often found. The anti-rat crusade promises to rid that city of two plagues.

Tuberculosis among the Foreign-Born.

There has long been an opinion among medical men that Irish-born people in this country were more liable to tuberculosis than those born of parents of other nationalities. This subject received some attention at the International Congress recently held at Washington. The prevailing opinion as to the liability of the Irish immigrants to develop tuberculosis was confirmed, but it was shown that children born of Irish parents were more susceptible to the disease than their foreign-born parents. It appears that the Italians and the Greeks are more liable to tuberculosis in this country than in their own country. It is susceptible of demonstration that the Italians do not bring the disease here but that they acquire it in this country. The same statement is believed to be true of the Greeks. The immigrants from both countries are for the most part peasants and of a hardy class, but when they enter this country they seek occupation in cities and live under the most unhygienic conditions. In striking contrast with the immigrants from Southern Europe in their susceptibility to tuberculosis, and also the Irish, are the Jews, who though similarly exposed to the unfavourable conditions of city life and often infected with tuberculosis, yet have a resisting power which gives a small comparative mortality. The only explanation which has been made of the immunity of the Jew is that he has for centuries been accustomed to urban life and therefore is acclimatised.

Nov. 27th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Garlic.

FROM time immemorial garlic, which is grown all over India, sold in every bazaar, and used very commonly as an ingredient in curries, has had a high reputation in domestic medicine and also in the ancient systems of the Hindu writers. It is recommended by the earliest of these authorities—Shushruta—for improving the voice, intellect, and complexion, promoting the union of fractured bones, and helping to cure nearly all the ills that flesh is heir to. Its use is by no means confined to India; in Ireland it is taken as an infusion together with whisky in colds and bronchitis, and farmers there and elsewhere apply it as a poultice in anthrax or "blackleg" in cattle. It was at one time officially recognised in the British Pharmacopœia and still maintains a place in that of the United States. It is known to contain a volatile oil—sulphide of allyl—to which its many virtues are attributed. In the *Indian Medical Record* there is a report by Dr. Minchin, Captain E. Blake Knox, R.A.M.C., and Dr. Kaviraj A. C. Bisharad on the use of garlic as a preventive of tuberculous disease. Several years ago an Italian physician, Dr. G. Cavazzani, made experiments by feeding guinea-pigs with garlic and then infecting them with tubercle. The results went to show that the guinea-pigs treated in this way were to a certain extent immune to tubercle, but the number of animals used was too few to make it possible to draw definite conclusions.

"Ratting."

In a report on rat destruction in the Punjab submitted to the local government Major S. Browning Smith, I.M.S., maintains that of all antiplague measures this is by far the easiest to carry out and the most readily acceptable to the people. As to methods, the use of traps has the great advantage over poisoning that it can be carried on continuously and thus be a permanent instead of a temporary measure. Experiments have been made with various substances for producing an infective disease among rats not communicable to man, but they have not been very successful. The rats that actually ate the virus died but no fatal epidemic ensued. Poisoning with phosphorus was equally effective and much less expensive. The results quoted instanced occurred in Glasgow, which was a natural city to which they would gravitate. So that Glasgow could be regarded as a favourable city for receiving those people who were carrying albinism as a recessive. The case quoted by Professor Pearson was not at all improbable from the Mendelian point of view—in fact, Mendelism would account for it quite well. With regard to the degrees of albinism, to which Professor Pearson had referred, he asked whether that gentleman regarded it as a case of continued variation, that the albino was merely the last stage in a graduated series of reductions of pigmentation. Or did that represent mutations? Professor Pearson must adopt one of those views. If he adopted the mutational conception the Mendelian school was to be congratulated upon a convert. He (Mr. Mudge) defined an albino as an organism in which there is complete absence of pigmentation other than the blood and bile pigments—in other words, it was an organism in which all the epiblastic pigmentation was absent. He did not know why Professor Pearson emphasised the existence of all grades. It was necessary to nail one's colours to the mast. A Mendelian was prepared to say that an albino came out of a wholly pigmented animal as a sudden sport or mutation and that it did not pass through those stages at all. The biometrical position was based on the assumption that those stages were stages which that organism, the complete albino, had passed through in the course of development. With regard to partial albinism, the Mendelians did not regard those so-called partial cases as albinos at all; they were not so in any sense; they were simply individuals in whom the amount of pigment had been reduced. There were certain biological considerations which he did not think Professor Pearson had given great prominence to with regard to human albinos—namely, the late development of certain characters. In rats, mice, guinea-pigs, moles, &c., when they were born they were born in an incomplete condition with regard to pigmentation; their eyes were black but their hair contained no pigment, and their skin was pigmentless. If those animals failed to develop pigment in their skin in later life they would have grown up albinos, they would not be partial albinos, and in that case there was something not albinotic but pathological. Very many human babies when born had blue eyes and fair hair. He had been trying to find out whether all babies were of that nature when born, but medical men seemed uncertain about their answer. If those babies born with blue eyes and fair hair stopped short at that stage they would be albinos; the organism would not be a partially pigmented one but would be an instance of arrest of development. That seemed to be the case in regard to nearly all the intermediate grades of albinism in man. It was known that when the so-called partial albinos were born they were very much less pigmented than they afterwards became; they later developed a little pigment but never became normal in that respect, except in one or two cases where an approach to normality was reached. But those cases could not be looked upon as stable products—they were not albinos; later they developed more pigment in the choroid and iris and there was more colour in the hair. Moreover, such conditions might be pathological and might be due to an arrest of development. Another thing which they might be was a variation or mutation *per se*. There was no evidence in man that that partial albinism had arisen as a mutation, but in the lower forms of animal life some remarkable cases were known, including the case of the flower which Professor Bateson pointed out many years ago at a meeting of the British Association, and what related to the flower related also to man. In connexion with the various grades of colour as they were recorded, in the pea flower from crimson to white, the history of the series showed that the white appeared before the other members of the series, which discounted any idea that they were a gradual progression. Mendelians took their stand on the mutational platform and biometricians on the continuous piling up of small fluctuations. Mr. Mudge instanced parallel cases in regard to the hair of sheep, and such instances, he said, would enable the medical men present to recall cases of hare-lip and microcephalic idiocy, club-foot, and alkaptonuria. The stand which the Mendelian took in regard to all those matters was one which was of very great interest to the medical man. Mr. Mudge next proceeded to show that all tabby cats in London could be placed into one of two groups: one in which there was one line running down the middle of the back and the stripes passed off vertically outwards over the side. In the other class there were three longitudinal stripes and the branching lines were arranged obliquely with a peculiar terminal curve. It was for Professor Pearson and his friends to find out an intermediate stage between those two. The point of interest was that those tabby cats had bred generation after generation, probably back to the sixteenth century, yet they were as distinct to-day as at the earliest known time. They afforded clear evidence of the existence of mutation in nature. And an even more important fact was that here was a clear segregation. Brachydactylia was another mutation, and that mutation behaved entirely on the Mendelian fashion. Dr. Drinkwater had shown that perfectly clear recessives might separate out and give one half normal and one half abnormal in their progeny. The value of the biometrical idea could be judged by an appeal to the results. Professor Pearson said that the albino pedigrees failed utterly to support Mendelism, and similar statements had previously been heard from Professor Pearson, in support of which he quoted from p. 213 of the article on colour in man in the *Biometrika*, Vol. II. There Professor Pearson said: "No single colour breeds true to itself, nor do we find that two black-eyed human beings, nor two blue-eyed human beings mated together give any sign of the dominance of one or other of these extremes." And then towards the end of the article Professor Pearson gave what was supposed to be the sting of it: "That nothing corresponding to Mendel's principles appeared in the characters for eye-colour in man." It so happened that eye-colour in man had been subsequently investigated in England by Hirst and in America by Davenport. The former investigation was conducted in a Leicestershire village and disproved the assertion of Professor Pearson as completely as possible. The inquiry showed that the dominant character when mated bred true. Mr. Mudge exhibited tables showing the results of various forms of mating. A further investigation had been made with regard to the colour of the coats and eyes of horses. Professor Pearson said: "It is the same with every coat colour taken, its relative constancy depends largely on the extent to which it has appeared in the ancestry, and one by one black, bay, chestnut, grey must be dismissed by the Mendelian as neither recessive nor dominant, but as marking permanent and incorrigible mongrels." "It is just worth reiterating," Professor Pearson said, "that nothing corresponding to Mendel's principles appears in eye and coat colour for horses, dogs, and men." But once more an appeal to facts showed that that statement was incorrect. Careful notes were taken of the particulars of 1104 cases of chestnut foals which had been produced from chestnut parents, but it was only fair to say that there were nine exceptions. When those exceptions were carefully examined it was found that they were due to want of care in the pedigrees which had been kept by the horses' breeders, because it was admitted by the breeders that they altered their records, both in the *Racing Calendar* and in the "Stud Book." But even then there were only nine exceptions out of 1104. Professor Pearson wanted the meeting to believe that his biometrical methods were accurate and definite, but he asked his hearers to look at Professor Pearson's "Grammar of Science," pp. 437, 446, 451, 458, 461, where hypothesis upon hypothesis was stated and interwoven with the fabric of his work. One had to recall the heated controversy between Professor Pearson and Professor Kapteyn, showing that it was imperative to wait yet a little while before trusting material collected to the methods of biometricians.

Professor **Karl Pearson**, in a rejoinder to Mr. Mudge's criticisms, said that he could only accept the challenge and carry the war into the enemy's camp. Biometry was neither Mendelism nor any other form of "ism"; it was an attempt to apply exact statistical methods to any statistics at all. And his complaint about the Mendelian school was that in nine cases out of ten its followers had not the elementary knowledge of how to deal with numbers. This he illustrated by several examples. With regard to albinism, his point was that without a *post-mortem* examination the exact colour and position of the pigment in an eye could not be discovered. In the few cases of eyes of supposed albinos pigment was found to be present in the eye. Professor Pearson exhibited on the screen by means of the epidiascope a number of slides of men of varying colour and of hair of varying colour. It was only by massing up the material and getting a very large number of pedigrees that any idea could be formed of the frequency with which exceptions was ready for her but recalled him owing to the grave state of the Emperor. On the evening of Prince Ching's return the Emperor died and at 2 A.M. the following night she called together the Grand Council who knelt round her bed and settled with her there and then the selection of the new Emperor. Two hours later the Grand Council assembled to discuss some other important points but she could only wave them aside and say that she was too weak to speak. From that point on she gradually sank, the dysenteric symptoms persisting to the end. It is interesting to note that the Court physicians have all been officially fined for their lack of ability to save their august patients. This is in accordance with precedent and is part of the custom by which the physicians draw salaries while the patient remains well but cease to do so as long as there may be any illness.

Plague in North China.

The outbreak already noted at Tongshan has, as was expected, subsided with the onset of cold weather and the death-rate has dropped to an average of one or two cases a day. There will be keen cold weather for the next four months with the thermometer registering as much as 25° of frost and a breathing space will be given to the sanitary authorities to set their house in order and have all arrangements made to meet a probable recrudescence next spring. The Chinese Engineering and Mining Company have engaged the services of an Indian Medical Service officer from the plague laboratory at Bombay, and are arranging for him to coöperate with the local public health staff. A feature of the recent epidemic has been a much higher percentage of pneumonic cases than has been met with in India or Hong-Kong. The proportions of the different varieties have been as follows: bubonic, 50·9; intestinal, 17·0; pneumonic, 11·6; and septicæmic, 11·5. The Chinese expectorate everywhere—in their houses and shops as well as in the open—and the difficulty of preventing the native miners from spitting while down in the mines has made the local sanitary authority (a French medical man in the employ of the Chinese Government) put an embargo on the export from Tongshan of coal, bricks, and cement. This is an interference with trade which is too important to be borne lightly and measures are being devised to have the prohibition removed. So far the great populous centres of Peking and Tientsin have remained plague-free. Dr. Moorhead, the company's medical officer, has worked hard to limit the spread, and Dr. J. M. Atkinson, the principal medical officer of Hong-Kong, has been on the scene of the epidemic giving much helpful advice.

The Heathen Chinee.

At Shanghai recently a Chinese doctor and his two assistants were charged with extortion from native drug shops. Their plan was for one to visit a shop and to buy 20 cents. worth of medicine. A few days later the three men would go to the shop and complain that their business had been ruined in consequence of the medicine having killed their patient. The drug was always of a harmless nature, but fearing prosecution by the indignant doctor the druggist paid up freely. On seven occasions this plan had succeeded, but at length their fame spread and complaint was made with the result that the doctor was sentenced to 12 months' imprisonment and his assistants got six months each.

Peking, Nov. 17th.

Obituary.

WILLIAM ALFRED ELLISTON, M.D. ST. AND., M.R.C.S. ENG., L.S.A., J.P.

ON Nov. 27th Dr. W. A. Elliston of Ipswich, one of the best known of the medical profession in East Anglia, passed away. He was the son of William Elliston, also a medical man, who with many other boys had been an apprentice of John Denny, a retired naval surgeon, who had a great reputation for training youths for the medical profession. Among Denny's pupils were Gull and George Sampson who became in process of time W. A. Elliston's uncle. When the latter in his turn entered the medical profession he commenced his training by apprenticeship to his uncle and when out of his articles he entered the medical school of Guy's Hospital. In 1862 he graduated at St. Andrew's and also took the diplomas of M.R.C.S. Eng. and of L.S.A. Lond. Owing to his father's failing health he had at once to take up the family practice and on his father's death he was elected to various public appointments, such as medical officer to the Ipswich workhouse and to the Poor-law Children's Home. In 1871 he was elected on the honorary staff of the East Suffolk and Ipswich Hospital. He took great interest in the surgical side of his profession and was an active advocate of Listerian principles. For the next 30 years Dr. Elliston led an exceedingly busy life, for besides his ordinary practice he was in constant request as a consultant. He took a deep interest in the British Medical Association, being for 20 years President of the East Anglian branch. When that branch resolved to invite the Association to meet at Ipswich in 1900 Dr. Elliston was unanimously nominated President by the branch and the nomination was duly confirmed by the Council.

The Ipswich meeting is memorable for two things, the one that at it our present King, then Prince of Wales, was elected an honorary member of the Association, and the other that it was the occasion for the appointment of the constitution committee, the outcome of which was the representative body. Dr. Elliston's interesting presidential address dealt with the historical aspects of medicine and he naturally laid special stress upon the many worthies of science who were connected with East Anglia. Such were William Gilbert, Sir Thomas Browne, the two Pagets, Sir William Gull, and Sir Thomas Watson, to name only a few. Dr. Elliston was a great believer in the theory that every medical man should have some interest outside his immediate professional work, and he did not stop short at theory. He was a member of the county bench of magistrates, and early in his career he furthered the cause of the Ipswich Working Men's College, at which institution he used to give lectures in hygiene, chemistry, and physics with popular illustrations. He was one of the founders of the Colonial College at Hollesley Bay which came into existence in the early "eighties." But although a good many pupils passed through the college it was not a financial success and the buildings are now the headquarters of the Central Unemployed Committee. Dr. Elliston was one of the founders of the Felixstowe golf club and of the Ipswich golf club, while in his younger days he hunted. He was a good swimmer and fond of walking. He retired from active professional work in 1901 and settled at Felixstowe, a place in which he had always been interested as a possible health resort. Dr. Elliston was for many years a vice-president and a member of the council of the Medical Defence Union. He was President of the Union in 1905 and 1906.

The funeral took place on Nov. 30th, the first part of the Burial Office being said at the church of St. John Baptist, Felixstowe, and the interment taking place at Ipswich cemetery. A large number of relatives and friends attended, the British Medical Association being represented by Dr. B. H. Nicholson, a member of the council; the Medical Defence Union by Dr. M. Beverley and Dr. E. G. Barnes; the corporation of Ipswich by the mayor; and the East Suffolk and Ipswich Hospital by Mr. Herbert Mason, the chairman.

ROBERT ALLEN, M.B. R.U.I., F.R.C.S. IREL.

THE death of Dr. Robert Allen took place at his residence, Queen's Elms, Belfast, from pneumonia, after a very short illness, on Dec. 2nd. Born at Portadown in 1869, Dr. Allen was educated at Queen's College, Galway, and graduated M.B. of the Royal University in 1893. In 1894 he was awarded the Travelling Medical Scholarship of the Royal University and as a result spent some time in medical study in Berlin and elsewhere on the continent. On returning home he became lecturer on anatomy in Queen's College, Galway, and resident medical officer of Galway Hospital. In 1900 he obtained the studentship of the Royal University in pathology and bacteriology. It was in 1895 that he began practice in Belfast and soon confined his attention to diseases of the throat and nose. In 1902 he was appointed assistant surgeon to the Ulster Eye, Ear, and Throat Hospital, and his work there fully maintained the high repute of that institution. Apart from his professional skill Dr. Allen was a man of great social qualities and hospitality, and was a very popular member of the profession. His widow is a daughter of thereto which were arrived at by the Committee on Physical Deterioration. By way of enforcing these conclusions the town council quotes the experience of Sir Frederick Treves as set forth in his account of the relief of Ladysmith: "In that column of 30,000 men the first who dropped out were not the tall men or the short ones or the big men or the little ones but the drinkers, and they dropped out as clearly as if they had been labelled with a big letter on their back." In the matter of pulmonary tuberculosis, a disease which is voluntarily notifiable, Dr. Thomas hopes that it may be feasible later to utilise a part of the small-pox hospital as a sanatorium. Good work appears to be done in Chester in the direction of food control, more particularly perhaps as regards milk. We note, for instance, that seven samples of milk were taken from refreshment rooms and that in two instances the deprivation of the milk from cream amounted to 67·3 and 26 per cent. respectively. It is satisfactory to notice, too, that prosecutions have been undertaken when the milk was found contaminated with filth, a substance which does not receive specific attention in the Public Health Act, 1875. There were six prosecutions for filthy milk, and in one case 1·69 grains of filth per gallon cost the milk vendor 44s. We regard this work of Chester as of great public utility. The water-supply of Chester is, we gather from the report, derived from the river Dee, and 200 samples were examined bacteriologically by the medical officer of health during 1907. On gelatine count the crude river water was found to contain from 550 to 52,800 colonies, the average being about 1500 to 2500. At periods of flood or at high tide the number was much greater and this reference to high tide seems to suggest that the intake is in some way or other within the sphere of tidal influence. In samples taken from the filtered water the gelatine counts ranged from 0-38, a fact which, as Dr. Thomas says, indicates the efficiency of the filtering process. Bacillus coli seems practically absent from the filtered river water. But Dr. Thomas is evidently uneasy, because there is in the filters only a single line of defence, and he quotes the historical instance of cholera at Hamburg and Altona as an illustration of what this single line of defence may mean. If, however, the Chester intakes are as exposed to pollution as were the Hamburg intakes we can well understand the uneasiness of Dr. Thomas, and from his comments we suspect that there may be a certain analogy as regards tidal influence between the two. But the position of the medical officer of health appears to be this. Given adequate storage we may rest assured, on the basis of Dr. A. C. Houston's work on the effect of water storage on pathogenic organisms, that the people of Chester need not lie awake at night with anxiety of water-borne epidemics. All this is very largely true and the history of London itself might be quoted in support of the view, but notwithstanding it a purer source is, we expect, desirable and we note that the council is arranging provisionally with the Birkenhead corporation for a supply from the upper waters of certain tributaries of the Wye.

County Borough of Wigan.—Mr. William Berry estimates the population of Wigan at 90,765. The birth-rate for 1907 was 30·5 and the illegitimate birth-rate was 1·37 per 1000 in each case. The infantile mortality reached the very high rate of 163 per 1000 births, but this rate includes 49 infants whose duration of life did not exceed 24 hours. There was no small-pox in the district during the year under review and consequently use was made of the small-pox hospital for the treatment of seven cases of pulmonary tuberculosis; the results were regarded as beneficial. There appears to be some difficulty in regard to obtaining supplies for the isolation hospital and as a result fewer cases were treated than would otherwise have been the case. The report contains no detailed information relating to this strange policy. There were 167 cases with 22 deaths from enteric fever, and personal contact together with privy middens are thought to be responsible for the prevalence of the disease. In the beginning of the year there was an outbreak of ptomaine poisoning caused, it appears, by the consumption of potted tongue, as in every instance tongue had been partaken of, and on bacteriological examination of the tongue the bacillus enteritidis of Gärtner as well as coliform organisms were discovered. Mr. Berry is inclined to attribute the contamination of the tongue to the brine which was used in its preparation, and he makes certain proposals for preventing these food-poisoning outbreaks. It is clear from this outbreak that far greater supervision over the actual preparation of foods is essential.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7175 births and 4863 deaths were registered during the week ending Dec. 5th. The annual rate of mortality in these towns, which had been equal to 15·6 per 1000 in each of the two preceding weeks, was again 15·6 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these towns averaged 14·7 per 1000, and in London the mean rate during the same period did not exceed 14·1. The lowest annual death-rates in these towns last week were 8·0 in King's Norton, 8·4 in Hornsey, 9·0 in West Bromwich, and 9·1 in York and in Smethwick; the rates in the other towns ranged upwards, however, to 23·7 in Middlesbrough, 24·2 in Huddersfield, and 24·5 in Swansea and in Rotherham. In London the death-rate last week was equal to 15·0, against 15·8 in the previous week. The 4863 deaths from all causes in the 76 towns showed an increase of but 16 upon the number in the previous week, and included 363 which were referred to the principal epidemic diseases, showing a further decline of 39 from the numbers in recent weeks; of these 363 deaths, 142 resulted from measles, 70 from diarrhœa, 51 from diphtheria, 38 from "fever" (principally enteric), 33 from scarlet fever, and 29 from whooping-cough, but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 1·2 per 1000, against 1·4 and 1·3 in the two preceding weeks; in London the rate from these diseases did not exceed 1·0 per 1000. No death from any of these epidemic diseases was registered last week in Rhondda, Norwich, Southampton, Wolverhampton, Swansea, Northampton, or in six other smaller towns; the annual death-rate therefrom, however, ranged upwards in the other towns to 3·3 per 1000 in Tottenham and in Rotherham, 4·5 in Middlesbrough, and 4·8 in Leicester. The 142 fatal cases of measles in the 76 towns during last week showed a further slight increase upon the numbers returned in recent weeks and exceeded the number registered in any previous week of this year; they caused death-rates equal to 2·2 in Huddersfield, 2·5 in Rotherham, 2·9 in Tottenham, 3·5 in Middlesbrough, and 4·1 in Leicester. The deaths attributed to diarrhœa, which rose to 1134 in the third week of August, have since steadily declined and did not exceed 70 in the week under notice, a lower number than in any week since the end of June. The 51 deaths from diphtheria, showed a decline of 15 from the number in the previous week; they included, however, 20 in London and its suburban districts, and eight in Manchester and Salford. The 38 deaths referred to "fever" also showed a decline from recent weekly numbers, but caused death-rates equal to 1·1 in St. Helens, 1·5 in Grimsby, and 1·9 in Devonport. The 33 fatal cases of scarlet fever, on the other hand, showed an increase upon the low numbers in recent weeks; 18 were recorded in London and its suburban districts, five in Manchester and Salford, and three in Birmingham and Aston Manor. The 29 deaths from whooping-cough were fewer than in any previous week of this year, including, however, two in Wigan, equal to an annual rate of 1·2 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 3809 and 3831 on the two preceding Saturdays, had declined to 3747 on Saturday, Dec. 5th; the new cases of this disease admitted to these hospitals during the week under notice were 406, against 500, 421, and 495 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 334 and 318 in the two preceding weeks, further declined during last week to 295, and were 103 below the corrected average number in the corresponding week of the five years 1903–07. The causes of 47, or 1·0 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were again duly certified in Leeds, Bristol, West Ham, them to be struck off the Roll:—Grace Baker, that with intent to avoid inspection and supervision by the duly appointed officer of the local supervising authority she did not notify her intention to practise in the year 1908, but expressly declared that she did not intend to practise; that nevertheless she practised as a midwife during 1908. Mary Annie Barton, that being in attendance as a midwife at a confinement she did not take with her the appliances or antiseptics required by Rule E, 2; that she did not wash the patient's external parts with soap and water and swab them with an antiseptic solution before making the first internal examination, or after the termination of labour, as required by Rule E, 7; that she washed the patient once only during the lying-in period. Sarah Elizabeth Beardsley, that being in attendance as a midwife at a confinement she did not wash the patient at all until 17 hours after the confinement; the patient being ill on Oct. 6th, suffering from severe internal pain, she (the midwife) did not send for a medical man; that she habitually neglected to take the pulse and temperature of her patients. Charlotte Bradford, that on or about July 14th, 1908, she laid out the body of a child who had died from erysipelas, not having being in attendance on the child at the time of its death, in contravention of Rule E, 16; that she subsequently attended as a midwife at a confinement without having undergone adequate disinfection of herself, her clothing, and her appliances, as required by Rule E, 5. Sarah Brown, that being in attendance as a midwife at a confinement, the patient suffering from sore breasts on the second day, she did not call in a medical man, and also the baby being ill on the second day, she did not call in a medical man; that being in attendance as a midwife at another confinement and the child suffering from inflammation of the eyes and from thrush on August 18th, she did not call in a medical man. Elizabeth Ellis, that being in attendance as a midwife, the patient being very ill with puerperal fever, her pulse 126, and her temperature 104·8° F., she (the midwife) did not send for a medical man. Catherine Evans, that being in attendance as a midwife at a confinement, the infant's eyes being inflamed and there being umbilical inflammation and hæmorrhage, she (the midwife) did not send for a medical man; that she could not take the temperature of her patients, being unable to use a clinical thermometer. Sarah Ann Fitton, that being in attendance as a midwife at a confinement, excessive bleeding taking place, with persistently offensive lochia and shivering fits, she did not send for a medical man. Jane Folland, that being in attendance as a midwife at a confinement, the patient's perineum being seriously ruptured, she did not send for a medical man. Fanny Hartland, that being in attendance as a midwife at a confinement, the child suffering from inflammation of the left eye, she did not send for a medical man. Sarah Ann Lambert, that being in attendance as a midwife at a confinement, the child being premature and dangerously feeble at birth, she did not send for a medical man; notwithstanding that the patient suggested that a registered medical practitioner should be sent for in consequence of the child suffering from convulsions at noon on the following day she (the midwife) declined to do so. Hannah Naylor, that being in attendance as a midwife at a confinement, the case being one of miscarriage, she did not send for a medical man. Dinah Ann Peace, that at the Mansfield police court she was convicted of assault; that she was uncleanly in her house, clothing, and appliances; that she habitually neglected to notify stillbirths to the local supervising authority. Catherine Rhoda Emily Skoines, that being in attendance as a midwife at a confinement, the patient being ill and feverish and suffering from abdominal pains, she (the midwife) did not send for a medical man. Sarah Stevenson, that being in attendance as a midwife at a confinement, she used a piece of flannel for washing the patient's genital organs, in contravention of Rule E, 7; that being in attendance as a midwife at another confinement, the patient being ill with abdominal pain and headache, she did not send for a medical man; that being in attendance as a midwife at another confinement, the placenta not having been completely expelled two hours after the birth of the child, she did not send for a medical man. Mary Stokes, that being in attendance as a midwife at a confinement, the case being one of abortion, she did not send for a medical man; the patient being ill with vomiting and persistently offensive lochia, she did not send for a medical man. Eliza Allsop, that being in attendance as a midwife at a confinement she was uncleanly in her person, clothing, and appliances, and did not take with her to the confinement the appliances or antiseptics required by Rule E, 2. Edith Mary Peacock and Mary Sparks, for drunkenness. The following midwives were censured after charges alleged against them had been considered: Rosetta Bromley, Jane Deane, Fanny Froggett, Annie Maddocks, Annie Marian Palmer, Mary Rimmer, and Ann Sephton. Emily Langley and Mary Ward were cautioned after charges alleged against them had been considered. The consideration of the charges alleged against Catherine Walls and Maria Booth was adjourned.

UNIVERSITY OF LIVERPOOL.—The annual meeting of the University Court was held at the Town-hall on Nov. 28th. The Court sanctioned a rearrangement of the teaching of the subjects of therapeutics, pharmacology, materia medica, and pharmacy. The subject of therapeutics is now separated from that of pharmacology and a new chair of therapeutics has been established, to which Dr. John Hill Abram has been appointed. Pharmacology will in future be taught as a laboratory course, chiefly by means of demonstrations of the action of drugs. For the purpose of this course and for the conduct of pharmacological researches in the University a special department of pharmacology is in course of establishment. During the summer term of 1909 the course in this subject for medical students will be in charge of Dr. O. T. Williams, demonstrator of bio-chemistry. Materia medica and pharmacy have been placed in charge of Mr. P. H. Marsden who now conducts both lecture and laboratory courses. Mr. W. Thelwall Thomas has had conferred upon him the title of associate professor of surgery on the recommendation of the Senate. Mr. Thomas has recently presented to the Faculty a collection of specimens and photographs illustrating the subject of surgical pathology. They will prove a valuable addition to the surgical museum.

ASSOCIATION FOR PROMOTING THE TRAINING AND SUPPLY OF MIDWIVES.—A meeting of the council of this association was held at the office in Dacre-street, Westminster, on Nov. 26th. Dr. Salaman presided, and among those present were the Dowager Marchioness of Bristol, the Viscountess St. Aldwyn, the Lady Balfour of Burleigh, Lady Prideaux, Mrs. Arnold Gabriel, Mrs. Percy Boulnois, Miss Rosalind Paget, Miss Wilson, Sir Herbert George Fordham, and Mr. Francis Freemantle. Mrs. Wallace Bruce, chairman of the executive committee, made a report on the work of the executive committee and various sub-committees. 20 pupils had been trained in the course of the year besides those who finished their course in the first months and those who would enter before the close of the year. These were trained at the East Ham Home, East-end Mothers' Home, General Lying-in Hospital, and the Leicester Maternity Hospital. The training had been very successful and all the midwives were now at work. At the East Ham Home, a branch of the Plaistow Maternity Charity specially supported by the association, 669 cases had been taken during the first nine months, and 12,349 visits paid by the midwives and pupils; a most valuable and practical district training was thus given. In response to many appeals for advice the training sub-committee had drawn up two leaflets of suggestions for starting a midwife and for the formation of maternity clubs, copies of which can be obtained from the secretary. Mr. Arthur L. Leon, the honorary treasurer, stated that in response to the special appeal about £900 had been received towards the £5000 which the association hoped to obtain for pushing forward the work with increased activity. He urged the increase of annual subscriptions by which confidence could be felt in extending the work of the association. The lady collectors, with Mrs. Samuel Bruce as the leader, were continuing their valuable work. The amount spent on training during the year was about £400 besides the £100 subscribed to the upkeep of the East Ham Home. Much interest was shown by the members of the council present in the various questions brought forward, and special reference was made to the "method of work" which had been drawn up by the executive committee early in the year. It was agreed that often the best method was to help towards the maintenance of midwives during the term of working up a practice, and pending local organisation. There followed an interesting discussion on the best means of securing a uniform supply of

Hichens, and Robert Arthur Milligan. To be Captains: Herbert Henry Brown, John Gutch, John Charles William Graham, George Frederick Rogers, George Secretan Haynes, Benjamin Hugh Nicholson, Walter Malden, and Sydney Walter Curl.

Sanitary Service: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel William Robert Smith, from the 1st City of London Volunteer Rifle Corps, to be Lieutenant-Colonel with the honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908).

For attachment to Units other than Medical Units.—Captain and Honorary Major James Robertson Reid (Retired List (Volunteers)) to be Major (dated May 1st, 1908). William James Townsend Barker to be Lieutenant (dated July 27th, 1908). Surgeon-Captain Mark Purcell Mayo Collier, from the East London (Tower Hamlets) Royal Engineers (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 1st Eastern General Hospital: Surgeon-Major Joseph Griffiths, from The Cambridge University Volunteer Rifle Corps, to be Lieutenant-Colonel (dated May 6th, 1908). Surgeon-Captain Frederick Edward Apthorpe Webb, from the 3rd (Cambridgeshire) Volunteer Battalion, The Suffolk Regiment, to be Major (dated May 6th, 1908).

IMPERIAL YEOMANRY.

2nd County of London (Westminster Dragoons): Second Lieutenant the Honourable Alexander C. Harris resigns his commission (dated March 31st, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 6th Lancashire: The announcements of the resignation of Surgeon-Captain Francis W. Bailey and of his appointment to a Captaincy, which appeared in the *London Gazette* of April 10th, 1908, are cancelled.

Rifle: 1st (Hertfordshire) Volunteer Battalion, The Bedfordshire Regiment: The undermentioned officer resigns his commission (dated March 31st, 1908): Surgeon-Captain Henry H. L. Patch.

Royal Army Medical Corps: Bedford Bearer Company: Captain Charles H. Perram resigns his commission (dated March 31st, 1908).

The *Army and Navy Gazette* of Dec. 5th, states: "The following movements of army medical officers may be calculated on. Colonel H. R. Whitehead, from India, to be promoted to surgeon-general, and to assume the principal medical officership of the Southern Command, vice Surgeon-General W. S. Pratt, due to retire by age on Jan. 21st. Colonel P. M. Ellis will succeed, on promotion to higher rank, to Surgeon-General W. B. Slaughter's vacancy in India, the latter officer being due to retire by age on the 31st inst. Great credit is due to the office of the Army Medical Service for the heavy work done and doing in carrying out the details of the Territorial scheme, the completion of which may be shortly expected."

Correspondence.

"Audi alteram partem."

SYPHILIS IN UGANDA.

To the Editor of THE LANCET.

SIR,—On reading the leading article "Syphilis in Uganda" in your issue of Oct. 3rd last I feel bound to express my dissent to some of the data on which it is based. I unfortunately had not the pleasure of meeting Colonel Lambkin in Uganda on his visit to that country as I was then in England on leave, though my brother, Mr. J. Howard Cook, M.S., F.R.C.S., who is associated with me in charge of this hospital, did so. I went back to Uganda almost immediately on Colonel Lambkin's return to England and so missed him again.

During the last 12 years I have repeatedly traversed Uganda from north to south and east to west, visiting also all the surrounding countries—Ankole, Toro (three times), Bunyoro (three times), Busogo (three times), Kavirondo (twice), Acholi Land, and the Southern Sudan. Our mission hospital was founded early in 1897 and has been expanding ever since till for the last two or three years we have had 120 beds. From the first we have kept careful notes and statistics of our in-patients and from 1902 of our out-patients. Turning, then, to our recent figures I find that last year 13,388 separate out-patients attended our mission dispensary. Of this number 1978 were syphilitic, a proportion of 14·8 per cent., bad enough in all conscience, but nothing like the words in your article, "at the present time more than half the population of the Protectorate is infected." I am convinced the proportion of syphilitics is higher here (as Mengo is the native capital) than anywhere else and feel sure that 90 per cent. in Ankole is far too high. It was certainly nothing like that when I was there. If only 14·8 per cent. were infected of those who attended our dispensary the number in the general population is surely much less.

Turning to the in-patients, the number of in-patients admitted to the hospital and of syphilitic in-patients respectively for the last five years are as follows:—

	Total in-patients.	Syphilitic.
1903	914	108
1904	1021	134
1905	1379	154
1906	1768	204
1907	1536	159
Total	6618	759

This works out at only 11·4 per cent., and as we have two wards set apart for the reception of syphilitic cases and draw our patients from a very large area I believe we get the great bulk of the more severely diseased syphilitics in the most densely populated part of the Protectorate. The cases of pregnancy complicated by syphilis, recent or old, is undoubtedly very high. I believe it to be about 25 per cent., but have not yet worked out sufficiently large figures to lead to trustworthy results.

You say "Colonel Lambkin found a prevalent opinion among medical men in the Protectorate that the natives were bad subjects for the administration of mercury, but this view has not been sustained by his own experience." While admitting the great superiority of his intra-muscular method I am bound to say that I fully share the opinion of my medical *confrères*, and though salivation is more uncommon after Colonel Lambkin's treatment we have had several serious cases after its use and a neighbouring medical man has had a death, though he admitted that in that case he had probably used too high a dose. By the mouth our usual dosage is one-eighth of a grain of grey powder twice or thrice daily and many can only stand this with astringent mouth washes for from two to three weeks. A single dose of five grains of calomel is almost sure to salivate. I fear Colonel Lambkin is premature in assuming "that it is possible to count upon even more complete control over the patients in Uganda than in India, the influence of the chief over his people being remarkable." This influence is rapidly dying out and I fear that the hold of the chiefs over their people in such a matter as periodical injections for syphilis would be extremely small.

Finally, I must give emphatic denial to the assumption that Christianity has been the chief cause of this epidemic. It has been all the other way. Read "civilisation" for "Christianity" and there may be some amount of truth in it. Respect for your valuable space forbids me to labour this point, but I venture to assert, Sir, that Christianity from the beginning has acted as a deterring and restraining force and is indeed, when intelligently accepted, the only true prophylaxis to this terrible scourge. In spite of my belief that the infection of Uganda by syphilis has been greatly overstated I feel certain that we owe a debt of gratitude to Colonel Lambkin for his intra-muscular method which we are practising on an ever-increasing scale and which we find is superior to any other remedy in suitably selected cases.

I am, *Sir, yours faithfully*,

ALBERT R. COOK, M.D., B.Sc. Lond., B.A. Camb.

C.M.S. Hospital, Mengo, Uganda, B.E. Africa, Nov. 3rd, 1908.

"THE HUMAN WOMAN."

To the Editor of THE LANCET.

SIR,—Referring to the interesting leading article on "The Human Woman" in THE LANCET of Nov. 21st, I should like to make a comment on the following sentence: "It may be conceded fairly that medical women of the present day are entering the lists on equal terms with medical men, at least as regards education; it will be interesting to see what proportion of medical women as compared with men 50 years

Heaven." Miss Hare, an old member of the school, who is the enviable possessor of a charming mezzo-soprano voice, sang songs by Goring Thomas, Brahms, and Loder, and Mr. Godfrey among other songs gave that delightful old Somerset folk-song in the Dorian mode, "I'm Seventeen come Sunday." Dr. Phear's tasteful accompaniment was by no means the least important feature of a most pleasant evening.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Lotteries and Indecent Advertisements.

The report of the Joint Committee of both Houses of Parliament, which some months ago investigated the subject of lotteries and indecent advertisements has been issued, along with the evidence, as a Parliamentary Blue-book.

The Withdrawal of the Education Bill.

The withdrawal of the Education Bill by the Government, in addition to the other consequences, removes the opportunity of discussing the question of the education grant with reference to the medical inspection of school children. Before the decision of the Government had been arrived at the Earl of Crewe stated in the House of Lords that the subject might be raised on one of the clauses of the Bill.

Hop Substitutes.

The Chancellor of the Exchequer has presented a Bill in the House of Commons to prohibit the use of hop substitutes in brewing and the importation of hops except in bags properly marked. It has been read a first time.

The White Phosphorus Matches Prohibition Bill.

The White Phosphorus Matches Prohibition Bill has made rapid progress during the past week. It was considered on report and read a third time in the House of Commons on Thursday, Dec. 3rd. On Tuesday, Dec. 8th, it received a second reading in the House of Lords.

Public Health (Regulations as to Food) Act.

Copies of the (1) Public Health (Foreign Meat) (Ireland) Regulations, 1908; and (2) Public Health (First Series, Unsound Food) (Ireland) Regulations, 1908, which have been made by the Local Government Board for Ireland have been presented to the House of Commons and been ordered to lie upon the table in the usual manner.

HOUSE OF LORDS.

Wednesday, Dec. 2nd.

Medical Inspection of School Children.

Viscount Galway called attention to the fact that no grant had yet been received by county councils towards the expenses incurred for the medical inspection of school children. He said that a great many local [illegible] into force until they knew [illegible] the Government. [illegible] when the figures of the [illegible] regard to education were examined there would not only be no grant for medical inspection but also an insufficient grant for other purposes.

The Earl of Crewe said that it was clear that the first cost of medical inspection must fall on the education rate. The question had been considered in connexion with what had been said as to grants on behalf of the Board of Education by Mr. McKenna when he was President of the Board. A White Paper had been issued explaining the financial proposals of the Education Bill of 1908. The effect of it was that several kinds of grants which were now given to the schools should be amalgamated and only a single grant should be given: Mr. McKenna had made it clear to a deputation that if help was to be given from central funds for medical inspection it must be given in a general grant and that it was not the intention of the Government to support a special grant for that purpose. Since that time, however, the situation had changed and the financial proposals were to form part of the Bill which had been recently introduced in the House of Commons in the same way as they formed part of Mr. McKenna's Bill. This fact made it difficult to enter into any financial details on the present occasion, but he understood that the clause which embodied them would be considered according to the allotment of business in another place on Monday, when the whole subject would be argued out. When the statement had been made noble lords could, of course, reopen the question as to the adequacy of the grant to meet this particular charge. It was generally admitted that medical inspection if properly carried out must involve a new burden on the local authorities. On the whole, however, he assured noble lords that the Board of Education was fully aware of the importance of the subject and that it recognised the fact that a very substantial charge must be placed on the local authorities by the measure of last year.

HOUSE OF COMMONS.

Wednesday, Dec. 2nd.

The Weir Hospital Bequest, Streatham.

Sir Henry Kimber asked the honourable Member for the Barnstaple Division, as representing the Charity Commissioners, whether, and when, the Charity Commissioners proposed to seal the scheme they were preparing respecting the diversion of the trust fund bequeathed by the late Mr. Benjamin Weir of Streatham; whether they would afford the Member for Wandsworth and the inhabitants of Streatham in the borough of Wandsworth a final opportunity of perusing it before it was actually sealed; and whether they would postpone the carrying out of the scheme until such time as the matter could be debated on some Vote in Supply next session.—Mr. Soares replied: The Commissioners propose to seal the scheme on Tuesday next. I will send the honourable Member a copy of the scheme to night. The answer to the last part of the question is that the scheme will be carried out in the ordinary course

Pulmonary Consumption amongst Irish Labourers.

Mr. Ffrench asked the President of the Local Government Board whether he was aware that [illegible] instances, having returned to [illegible] had been found suffering from [illegible] sleeping [illegible] which Irish farm labourers were permitte[illegible] whether he was aware that these houses w[illegible], in which the men had to sleep in coarse bags on the floor; and whether the sanitary authority could compel English farmers to give proper sleeping accommodation to their labourers; and, if so, would he see that the law was put in force.—Mr. Burns furnished the following written reply: I am not in possession of any information to show that pulmonary consumption amongst Irish labourers has been caused in the way suggested. At the same time, I am aware that the temporary accommodation provided for migratory labourers, such as navvies, hop-pickers, [illegible] ot infrequently used for those [illegible] ccommodation is often unsatis[illegible]. One of the medical inspectors of the Local Government Board is, by my direction, now engaged in investigating the conditions under which migratory labourers are housed. A report which he has already made with regard to hop-pickers has led to action being taken by the local authorities, and I am shortly expecting a further report from him in relation to other branches of the subject, which will, I believe, contain some definite recommendations with regard to the matter.

Thursday, Dec. 3rd.

Poisons and Pharmacy Bill.

Mr. H. Samuel, in moving the second reading of the Poisons and Pharmacy Bill, said that Clause 1 of the measure brought up to date the Schedule of Poisons contained in the Pharmacy Act, 1868, in the [illegible] ired in the last 40 years. Clause 2 dealt [illegible] of sheep-dips, weed-killers, and poisonous [illegible] of insect pests met with in agricultural and horticultural operations. Clause 3 dealt with companies carrying on the sale of drugs. Since this matter had been before a Joint Committee of both Houses of Parliament, negotiations had taken place between the Home Office, chemists, drug stores, and coöperative societies, and he was happy to say that agreement had been reached. He would have to move several amendments to the Bill in committee in pursuance of this agreement.

Mr. F. E. Smith expressed his satisfaction that a compromise had been reached but he thought that the right honourable gentleman should indicate the effects of the amendments which he would propose in committee.

Mr. Samuel explained that the effect of the clause as amended would be that a drug store company must have a duly qualified chemist in charge of the actual dispensing of medicines as under the present law, and, in addition, a superintendent to manage the poisons department of the company. If the company had only one shop the superintendent and the dispenser of [illegible] on, but if there was a number c[illegible] st in each shop to dispense the [illegible] manager of the poisons department who was also a [illegible] companies and chemists agreed on that [illegible] the whole question. The title of "pharmacis[illegible] chemists and druggists, but apart from that the drug store, which conformed to these conditions, might retain the title of chemist and druggist.

Mr. Ashley hoped that under the Bill it might be possible to curtail the sale of morphine. The insidious drug habit did great harm in this country not only amongst men but amongst women.

Mr. H. W. Forster welcomed the Bill as he thought that under it something might be done to restrain the sale of morphine and preparations of opium. The schedule of the Pharmacy Act of 1868 was repealed and a new schedule containing these substances was substituted for it in the present Bill. There was no doubt that the drug habit was on the increase. It was one of the most deplorable diseases to which a man or woman could succumb. In his capacity as a member of a voluntary committee before which such cases had been brought he had heard stories of misery which had almost brought tears into the eyes of even a hardened politician like himself. He thought everyone ought to feel gratitude for anything which would make it difficult for people to obtain these drugs.

Sir Henry Craik criticised the powers given in Clause 2 to tradesmen to sell various poisonous substances used by agriculturists and horticulturists. Was there any country in which fewer restrictions on the sale of poisons were imposed? Why should the general health of the community be disregarded and proper scientific precautions not be taken, and this widespread sale of poisonous substances be allowed, because it would be a little more convenient for the farmer to get his sheep dips and weed killers from the nearest shop? It was a dangerous relaxation of the law such as would not be permitted in any other country.

Mr. B. Straus hoped that the Government would make it impossible for the public to obtain dangerous drugs with the facility which they now obtained them. At present a patient got the prescription of a medical man for morphine and althoug[illegible] it was hawked about from druggist to druggist [illegible] it was intended had disappeared. The d[illegible] prescriptions and it should be made impos[illegible] them after the lapse of a month. A measure of that kind would be most popular with the medical profession and no more useful provision for the well-being of the people could be passed.

Mr. Samuel, replying to the debate, said that the question of morphine had been raised. The Bill did make a change in the law in that respect. It took morphine out of Part II. of the schedule of the Pharmacy Act of 1868 and put it into Part I. and thereby considerably this, like so many controversial matters, has not been made clear through a certain misunderstanding. All the other points I dealt with in my last letter (Nov. 14th) and there is no need to refer to them again. The point I allude to is in regard to the work of Borrel and Bridré. I stated, as I think Mr. Walker correctly quotes, that though there was a difference in technique between his work and theirs in regard to testis preparations, there was no essential difference in the principles involved or in the means by which it was hoped a result might be obtained. Let me make myself clear upon this point, for I have not done so as yet, since it appeared to me that Mr. Walker's results were as negative—in so far as a cure was concerned—as were those of Borrel and Bridré. But even disregarding this important fact I believe I am justified in considering that there is no essential difference between immunity produced by a vaccine (which was essentially what the testis preparation used by Borrel and Bridré appears to have been) and a serum immunised to testis (as carried out by Mr. Walker). This, of course, would not apply to ordinary somatic cells, but certainly should to those out of coördination—as those of the testis have been shown to be—if Mr. Walker's views were to have any application.

I made in the hasty abstract of my remarks a slip, which Mr. Walker refers to, in calling Borrel and Bridré's preparation "testis serum." I did not make this mistake in my speech nor in my subsequent letter. It was a clerical slip and nothing more, for I was well aware of the nature of the work done, as was evident in my spoken remarks when I classed and compared the testis preparation with that made from liver, spleen, and fœtal tissues. I hope I have made this final point clear, as I have no wish to clothe any of my remarks in ambiguity.

In conclusion, I trust that if my comments should have caused any unpleasantness my arguments will not have suffered from the inference that I was manufacturing a case. A careful perusal of my arguments will show that this is not so. I also wish to make it quite clear that I hold to all that I have said in regard to the scientific value of the work brought forward.

I am, Sir, yours faithfully,

W. BLAIR BELL.

Liverpool, Nov. 30th, 1908.

THE STERILISATION OF POTABLE WATERS BY MEANS OF CALCIUM HYPOCHLORITE.

To the Editor of THE LANCET.

SIR,—May I be allowed to say that it was hardly necessary for my friend Dr. Thresh to have gone to America to learn that chlorine is an economic and efficient agent for the purification of polluted drinking waters, as for the last three years I have had under observation at Guildford, Surrey, a method of sterilisation by chlorine which has already been referred to in the literature on the subject, and by Mr. Phelps and his colleagues in their papers published in America last year The Royal Commission on Sewage has since then found at Guildford that a small quantity of a liquid containing available chlorine could render septic tank liquids inoffensive and that if more than sufficient to remove smell and kill "coli" was added it did not prejudice the purifying ability of filters.

Dr. Thresh omits to state in his interesting paper advocating the use of calcium hypochlorite that Phelps and Carpenter as a result of their work at the Massachusetts station consider that electrolytic chlorine is cheaper and probably more efficient than chloride of lime for the practical sterilisation of impure waters and effluents. As the subject is to be discussed at a meeting of the Royal Sanitary Institute on Wednesday, Jan. 13th next, I will not trouble your readers with any further details except the following quotations from Messrs. Phelps and Carpenter's paper in the *Technology Quarterly* of the Sanitary Research Laboratory of the Massachusetts Institute of Technology :—

> The use of gaseous chlorine, manufactured at the disposal works by electrolytic methods, would in the case of larger works considerably reduce this cost.
>
> The process as thus outlined is entirely feasible, and in the case of large works it is cheaper than sand filtration.

I am, Sir, yours faithfully,

SAMUEL RIDEAL.

Victoria-street, Westminster, London, S.W., Dec. 3rd, 1908.

THE PROPOSED EASTBOURNE CENSUS.

To the Editor of THE LANCET.

SIR,—The attention of the town council of Eastbourne has been called to the annotation on p. 1698 of the current issue of THE LANCET, headed as above, and I was requested to forward the following resolution unanimously passed by the council, viz. :—

> That this council, having regard to the high standard of THE LANCET, feels that it is impossible to believe that the Editor of that paper can have seen the communication in the current issue on page 1698, suggesting that the inhabitants of Eastbourne are likely to falsify the census returns, and feels confident that his attention has only to be called to that objectionable statement to ensure his repudiation of it.

I am certain that the article in question must have escaped your personal attention and confidently hope that you will in your next issue adopt a course that will be satisfactory to the people of this town. I may add that the article has been extensively reproduced in the newspapers circulating in Eastbourne and the county of Sussex.

I am, Sir, your obedient servant,

MARK MARTIN,
Mayor.

Town Hall, Eastbourne, Dec. 8th, 1908.

⁂ No article in THE LANCET escapes our personal attention, so that we cannot avoid responsibility in the way his Worship suggests. But we read the sentence as much more general in its application, and must view any attempt by any community to prove its population up to a certain figure with suspicion. We gladly qualify the word "falsify," as having an offensive significance for persons interested, by saying that we intended to convey a feeling that every effort would be made to swell the returns, so that extraordinary care would have to be exercised to keep them trustworthy; and we should give the same warning in like circumstances to any community. It is human nature, not Eastbourne, that is frail.—ED. L.

THE OBJECTS OF EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—In connexion with this subject it seems to me that one point is not sufficiently clearly recognised. By asking a candidate even one single question on a piece of minute anatomy—such, for instance, as the lenticular ganglion, the petrosal and chorda tympani nerves, or the smaller surfaces of the palate bone—the whole level of an examination in anatomy is at once lowered from that of a practical subject of some use to that of a cram subject which is not only useless but calculated to do positive harm. The candidate says to his friends, "They asked me Meckel's ganglion," and at once everyone begins getting up not only Meckel's ganglion but a whole host of equally minute points the knowledge of which is only necessary for men who are engaged in research work. As Professor Starling has pointed out, the advent of the pressure forceps and of asepsis has changed everything. Not only so, but for diagnostic purposes facts such as those relating to the common nerve supply of the hip- and knee-joints are really of very little use; what really is of use is the clinical fact learnt in the out-patient room that pain in the knee is often an early symptom of hip disease. The examiners set the standard and it rests with them to insure that ancillary subjects are not out of all proportion to the rest of a student's training.

A good examiner helps a candidate to do his best, while a bad one deprives a man of confidence at the start and he probably goes from bad to worse. I was once asked a question at the beginning of a *vivâ voce* examination which I have never quite fathomed yet. It was this: "Under what conditions does elastic tissue occur in the body?" Now the hopeless confusion of theory and fact raised in one's mind by this question is appalling. If the examiner had asked, "In what parts of the body is elastic tissue found?" and had then said, "And what do you think are its uses?" we should have been able to get along nicely. Some men reckon an examiner's merits in terms of the number of doubtful candidates he is able to fairly help through. This is complicated by the question whether the examination is designed to help a candidate on or to keep him back. The former object is undoubtedly the right one.

Woman in Industry from Seven Points of View. By Gertrude M. Tuckwell, Constance Smith, Mary R. Macarthur, May Tennant, Nettie Adler, Adelaide M. Anderson, and Clementina Black. With a Preface by D. J. Shackleton, M.P. Price 2*s.* 6*d.* net.

FISCHER, GUSTAV, Jena.

Neuere Ergebnisse auf dem Gebiete der Speziellen Eiweisschemie. Von Emil Abderhalden, o. Professor für Physiologie an der Kgl. Tierärztlichen Hochschule, Berlin. Price M.3.50.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BERKELEY, COMYNS, M.B., B.C. Cantab., M.R.C.P., has been appointed an Examiner in Midwifery and Diseases of Women to the University of Oxford.

EMRYS-ROBERTS, EDWARD, M.B., Ch.B. Vict., M.B., Ch.B. Liverp., has been appointed Pathologist to the Bristol General Hospital.

JONES, D. W CARMALT, M.B. Oxon, M.R.C.P., has been appointed Assistant Physician to Westminster Hospital.

PATTON, J., M.B., B.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ederney District of the county of Fermanagh.

RAMSAY, JEFFREY, [illegible] Surgeon at the Bl[illegible]

SEMPLE, M., M.D., [illegible] under the Factory and Workshop Act for the Cong District of the county of Mayo.

WHITLOCK, ADA MILES, M.B., B.S. Lond., has been appointed a Medical Inspector of Schools by the Gloucestershire Education Committee.

WILLIAMS, T. GEE, M.B., Ch.B. Manch., has been appointed Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH, EASTERN DISPENSARY.—Resident Medical Practitioner. Salary £130 per annum, with apartments, coals, gas, and attendance.

BERMONDSEY MEDICAL MISSION.—Resident Assistant (female) for six months. Board and residence provided.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House Surgeon. Salary £70 per annum.

BIRMINGHAM, QUEEN'S HOSPITAL.—House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

BIRMINGHAM, UNIVERSITY OF.—Lecturer in Physiology. Stipend £150 per annum.

BLACKPOOL, COUNTY BOROUGH OF.—School Medical Officer (female). Salary £200 per annum.

BRISTOL ROYAL INFIRMARY.—Ophthalmic and Obstetric House Surgeon. Salary £75 per annum, with board, lodging, and washing. Also House Physician.

CANCER HOSPITAL, Fulham-road, London, S.W.—Assistant Anæsthetist. Salary 25 guineas per annum.

CARDIFF CITY MENTAL HOSPITAL, Whitchurch.—Junior Assistant Medical Officer, unmarried. Salary £170, with quarters and all found.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon for six months. Salary £30, with board, residence, and laundry.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Registrars.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, washing, and residence.

DERBYSHIRE ROYAL INFIRMARY.—Two House Surgeons, One House Physician, and One Assistant House Surgeon. Salary of three former £100 per annum, with apartments, board, &c.; and of latter at rate of £60 per annum, with apartments, board, &c.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, &c.

DUBLIN, DR. STEEVENS' HOSPITAL.—House Surgeon. Salary £100 per annum, with apartments, fire, and light.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—Aural Surgeon, also Clinical Assistants.

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Assistant Physician.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £30, with board and residence.

HUDDERSFIELD INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with rooms, board, washing, and attendance.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary £30, with board, residence, and washing.

LINCOLN UNION.—Medical Officer. Salary £100 per annum and fees.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—House Surgeon. Salary £80 per annum, with board and residence.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—House Physician. Salary £60 per annum, with board and residence.

LONDON LOCK HOSPITAL, Dean-street, Soho.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

LONDON TEMPERANCE HOSPITAL.—Assistant House Surgeon, non-resident, for six months. Salary at rate of £75 per annum.

commission finds that, with the exception of four medical districts, quackery is already on the wane, and that among the general public, who really are the *parties most* concerned, there is no great wish for any reform in this respect. On the other hand, it is proposed that regulations already in force against quackery should be more strictly applied than heretofore, the principles on which these regulations are founded remaining as before.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

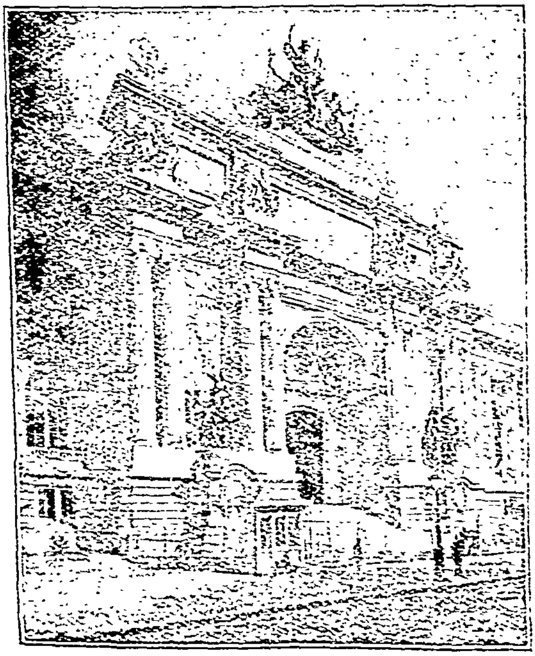
(FROM OUR SPECIAL SANITARY COMMISSIONER.)

WHY THE CONGRESS WAS BADLY HOUSED.—THE UNMANAGEABLE SIZE OF MODERN CONGRESSES.—NEED OF GOVERNMENT AID.—THE HUNT FOR PREMISES.—THE PRESSURE EXERCISED BY THE MEDICAL PROFESSION AND THE PARLIAMENTARY WRECKERS.—THE SUPPRESSED RESOLUTIONS AND THE VOICE OF SCANDAL.—THE ABORTIVE INTERNATIONAL COMMITTEE AND ITS BLUNDERS.—THE MORAL OF THE STORY.

New York, November, 1908.

ON the homeward journey, when waiting in New York for the steamer that was to take me back once more to Europe, I had an opportunity of discussing at length some of the shortcomings of the Congress with one of its principal and active organisers. It must be acknowledged that no congress of such importance has ever been so badly housed, the accompanying reproductions of photographs showing by contrast more than words can express. The first is the entrance to the Grand Palais at Paris where the Second Congress on Tuberculosis was held; the second is the entrance to the building where the Third Congress was held, the size of the figures showing that the reproductions have been arranged on practically the same scale.

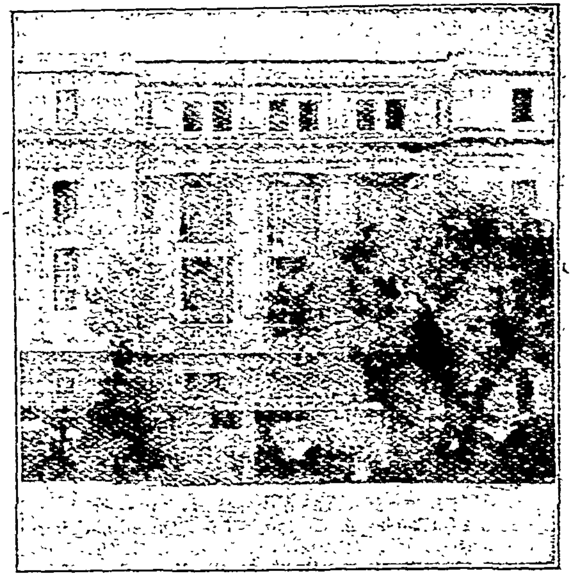
FIG. 1.



Reproduction of a photograph showing the Avenue d'Antin entrance to the Grand Palais, Paris, where the Second Congress on Tuberculosis was held in 1905.

I was pleased to obtain, and this on the best authority, an account of what had occurred, leading up to such a poor reception of the Congress. It appears that, according to the American law, the Government cannot itself participate in receiving a congress. On the other hand, it may allow the Ministry which is particularly concerned in the object of a congress to take part in that congress. The vagueness of these conditions makes their strength. Thus though the spending of money over a congress is not expressly sanctioned, neither is it forbidden. Consequently it was fully expected that one or more of the Ministries, forming part of the Government, would aid the Congress. Nevertheless the National Association for the Study and Prevention of Tuberculosis set to work to raise a fund of £20,000 so as to defray the costs. For this purpose a special office was opened at Washington. Then the organising committee visited all the buildings in Washington to find a suitable place wherein the Congress might be held.

FIG. 2.



Entrance to the session of the Third International Congress on Tuberculosis held in the unfinished premises of the new Museum at Washington in 1908.

Here I would interrupt the narrative to enter an energetic protest against such lax proceedings as are here described. The rule for these large international congresses is that no invitation shall be accepted unless it is endorsed by the Government of the country from which the invitation emanates. It is then only natural to presume that a Government would not invite several thousand guests unless it has a suitable building in which to receive them. Therefore in 1905 the American delegates who invited the Congress to hold its next session in the United States and got Mr. Elihu Root, the Secretary of State, to confirm this invitation, should have assured themselves *first* that there was a suitable *locale* at their disposal and that the necessary money would be forthcoming. Indeed, this is the meaning of a Government invitation. It is quite evident that private individuals cannot provide palatial buildings and spend the thousands of pounds necessary to receive a great international congress. Precisely by reason of the difficulty and expense we have now reached the stage when these congresses are becoming unmanageable and a very earnest effort, it is hoped, will be made either to reduce their size or their frequency. The Sixteenth International Congress of Medicine will meet at the end of next August in the capital of Hungary, and it must be noted that an announcement has already been sent out to the effect that a proposal will then be brought forward to hold these congresses only once in four years instead of every third year. The difficulty of organising huge international congresses, to which this most recent incident again testifies, was recognised many years ago. The American delegates at the Paris Congress of 1905 had plenty of comparatively recent experience to warn them. There was fresh before them the history of the great crush at the International Congresses of Medicine and of Hygiene that met at Paris in 1900; and, above all, there was the appalling gathering of some 7000 persons under Government management, while the estate hospitals maintained by the planters are under Government supervision. The number of patients treated in the hospitals in 1907 was 28,708, of whom 1193 were Europeans; the corresponding figures for 1906 were 27,340 and 1103 respectively. The deaths numbered 3688 (74 being Europeans). The inmates of the various leper hospitals, the majority of whom are quartered at Pulau Jerejak, numbered 389 at the close of the year as compared with 391 in 1906. 135 deaths occurred, as against 154 in 1906.

Messrs. Cadbury of Bournville have sent us some specimens of their confections, which are excellently prepared and packed in neat and artistic boxes. Good chocolates are appreciated by most people, both young and old, and are, moreover, safe sweetmeats.]

◆

Curious.—We know of no work on mnemonics in connexion with medicine; every medical school has certain traditional mnemonics and some are common to many schools. As a rule, mnemonics are best when they are *home* made. The line to remind students of the order of the structures passing behind the internal malleolus is "Timothy doth vex all very nervous pupils." Timothy is supposed to refer to Mr. Timothy Holmes, who was, as a matter of fact, a kind as well as a just examiner, but who had an awe-inspiring manner.

J. C. (1)—To the best of our knowledge there is no preparation possessing the exact qualities desired. A dermatologist might be able to prescribe something *that* would be useful in a particular case but the symptom is not always dependent upon the same cause.

Mr. J. Jacobs.—Hospitals are compelled to make rules for the prevention of abuse and to assist them in their administrative work.

R. F.—The Students' Number of THE LANCET for 1906, under the heading The Student's Library, will give the information.

Duplex.—No; the numerous stories will not bear investigation, while the biological improbabilities are insuperable.

J. C. (2)—Our correspondent should put the matter before his medical adviser who might communicate with us.

I. C. U.—Certainly.

T. T.—Yes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—Arthur Whitfield, E. G. Graham Little): at 4.15 P.M.

Paper:

Dr. Colcott Fox: Endothrix Trichophytic Flora in London (illustrated by a collection of cultures).

Cases:

Dr. Graham Little: (1) Favus of Scalp and Glabrous Skin; (2) Anomalous Pigmentation.

Dr. Whitfield: An Unusual Secondary Syphilide.

Dr. Wilfred Fox: (1) A Case of Lichen Planus treated with Soamin Injections, with Toxic Signs; (2) (with Dr. Freshwater): A Case of Syphilis "Secondaire Tardive."

Dr. J. M. H. MacLeod: A Case of Cicatricial Alopecia.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—Hugh Lett, E. I. Spriggs, Harold J. Stiles): at 5 P.M. (Special Meeting).

Discussion:

Whooping-cough.

The following are expected to take part in the Discussion:—Dr. Carpenter, Dr. J. Walter Carr, Dr. Cautley, Dr. Leonard Guthrie, Dr. Newsholme, and Dr. Porter Parkinson.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretary—Reginald Morton): at 8.30 P.M.

Dr. Lake Hope (Brighton): The Value of Recent Improvements in Radiographic Technique.

Dr. William Martin (Newcastle-on-Tyne): The Biceps Tubercle and X Ray Examination—a Point of Medico-legal Value.

Dr. G. Harrison Orton (London) will open a Discussion on the X Ray Examination of the Accessory Sinuses of the Nose.

Dr. Horace Manders (London): Undamped Waves.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on Athletics in Relation to Disease (opened by Mr. R. H. A. Whitlocke (Oxford)). Sir Lauder Brunton, Bart., Dr. W. Collier (Oxford), Dr. A. Morison, and others, will take part in the discussion.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—8 P.M., Mr. P. McConnel: London Milk Supply from a Farmer's Point of View.

CHELSEA CLINICAL SOCIETY, Chelsea Dispensary, Manor street, Chelsea, S.W.

TUESDAY.—8 P.M., Clinical Evening. Cases will be exhibited by the President (Dr. A. F. Penny), Mr. A. Baldwin, Dr. A. Eddowes, Mr. A. H. Greg, Dr. C. J. H. Gunning, Mr. J. H. Evans, Dr. E. Pritchard, Mr. C. Ryall, Mr. R. Thompson, and Dr. S. Taylor.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Mr. J. E. Stead: (1) A Workshop Microscope for the Examination of Opaque Objects; (2) A Simple Method of Illuminating Opaque Objects.—Rev. E. Tozer: On Mounting Rotifers and Protista in Canada Balsam.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Dr. W. C. Hossack: The Present Position of the Rat Flea *Theory* of Plague; Recent Observations in Calcutta.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—12 (noon), Prof. Shattock: Fibroma. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: Clinique (Skin). 5.15 P.M., Lecture:—Mr. M. Little: A Demonstration of Orthopædic Appliances.

TUESDAY.—4 P.M., Dr. A. Morison: Clinique (Medical). 5.15 P.M., Lecture:—Mr. J. E. Lane: The *Treatment of Syphilis by* Arylarsonates

WEDNESDAY.—4 P.M., Mr. T. Walker: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. W. Stuart-Low: Nasal Obstruction, its Causes, Consequences, and Care.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. R. Jones (Liverpool): The Treatment of Congenital Club Foot.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Surgical Cases. 12 *noon*, Dr. *Low: Pathological* Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Dunn: Cases of Diseases of the Eyes.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Bidwell: The Causes of Disappointing *Results after* Gastro-enterostomy.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Beddard: Medicine.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Surgical Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Keetley: Clinical (with cases).

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pardoe: The Prophylaxis of Venereal Diseases.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. 2.30 P.M., Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought *Hospital, Greenwich.*

MONDAY.—2 P.M., Operations. 2.15 P.M., Sir Dyce Duckworth: Medicine. 3.15 P.M., Mr. Turner: Surgery. 4 P.M., Mr. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Mr. Lawrence: Hearing.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. *Morris:* Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., [illegible] F. Taylor: Medicine. 3.30 P.M., [illegible] Out-patient Demonstrations:—10 A.M., [illegible] 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., *Surgical* Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson); X Rays. 4.30 P.M., Medical In-patient Clinic (Dr. A. J. Whiting [illegible] Auld).

TUESDAY.—Clinic: 10 A.M., [illegible] Out-2.30 P.M., Operations (M[illegible] Giles). patient (Mr. W. Edmunc[illegible] losis. 4.30 P.M., Dr. R. M. Leslie [illegible] (Dr. T. R.

WEDNESDAY.—Clinics:—2[illegible] P. Brooks). Whipham); Skin (Dr. [illegible] of Mental 4.30 P.M., Dr. S. J. Gill[illegible] Disease at the *Colney* Hatch Asylum, N.

that the American Government would supply the necessary buildings and a sufficient subvention. Nevertheless, they had a promise from the Secretary of State and the support of the President of the Republic, and everything would probably have worked out satisfactorily but for the fact that two or three political wire-pullers failed to understand the importance of the Congress that was about to take place.

All this did not tend to make the international delegates take a lenient view of other shortcomings that followed on the initial one of unpreparedness. The climax was reached when on the Saturday morning the International Committee discovered that an attempt was to be made to suppress all the resolutions of the Congress. This I have already described,[1] but it appears that deductions have been made for which I can not be held responsible. Suspicion was first aroused by invitations given to a breakfast which was held at 8.30 on the Friday morning at the Hotel Villa. There were present at this breakfast some members of the American organising committee and apparently no foreigner excepting Professor Robert Koch. It was thought that the resolutions adopted in the sections were discussed at this breakfast, but I am assured by a delegate who was present that such was not the case and that the conversation ran principally on the question of where the next Congress should be held. But the plot seemed to thicken when it was found that the same set which met at breakfast held what has been qualified as a caucus meeting at 5 o'clock that same afternoon and that there was present at both these meetings the intermediary who had obtained from a former member of one of the greatest of the great American trusts a subscription towards the expenses of the Congress amounting, it was said, to no less a sum than $30,000. What made the Friday afternoon meeting appear like a caucus was the absence of nearly all the foreign members of the International Committee. The official delegate from Chili had been met in the corridors and persuaded to enter. This meeting appeared to him to consist almost exclusively of Americans and yet it was discussing the resolutions of the International Congress. This seemed to him so irregular that he wanted to leave, as he did not wish to be compromised by unwillingly taking part in the proceedings. Professor Koch was examining a resolution, and finally agreed to a recommendation for the boiling of milk. Of course, this was absolutely out of order. Professor Koch, it appeared, would not accept the resolution on bovine tuberculosis passed by the section which dealt with the subject. Obviously there was here a serious misunderstanding. Someone even went so far as to suggest that Professor Koch should himself frame a resolution just as if there had been no Congress and no meeting of the sections. Professor Koch kept saying that he could not accept, and that the Germans who followed his lead would vote against, this or that proposal. But even if this had been a proper meeting of the International Committee itself, it could not possibly have interfered with resolutions actually carried. A committee cannot alter the decision of a section. The Congress wanted to know how the sections had voted, and no amount of disapproval on the part of Professor Koch or of any committee could alter a vote duly taken by a section. In view, however, of Professor Koch's disapproval and also because there was some disagreement in regard to the wording of a resolution on the housing question, it was suggested that the resolutions carried in the sections were not of much importance. Then it was argued that the hurried vote given at the closing sitting was even less important than the vote of the sections and that, on the whole, it would be best not to mention the resolutions at all. With a carelessness and want of perspicacity which all concerned have now had leisure bitterly to regret this view was ultimately adopted.

In these circumstances the American organisers have really only themselves to blame if their action has given rise to incorrect interpretations. Perhaps some of them are old enough to remember the time when, if anything untoward happened in Europe, the opinion was at once expressed that it must be the fault of Bismarck. Such is the state of mind to-day in America. If anything goes wrong it is the fault of the trusts. If there is any fault to be found with the International Congress on Tuberculosis it is all the doing of the trusts. So here we have money traced to the trusts, a meeting irregularly held, and a far-off Chilian dragged in to give it a semblance of the international character which it did not possess, and then resolutions are suppressed. As a matter of fact, the delegate from Chili had attended more international congresses than some of the American organisers and was much better able to appreciate the blunder which they were committing.

The answer to the above attempt to interpret the events in a scandalous sense is, first and foremost, that in the war against tuberculosis any number of wealthy people have subscribed money and this has never prevented the denunciation of all the conditions that favoured the spread of the disease. If the medical profession could be influenced by money considerations they would not take the lead in the campaign against tuberculosis, as no disease affords a better source of revenue to the profession. With regard to the money subscribed for the expenses of the Congress the organisers were beholden to wealthy people who had endowed hospitals and dispensaries but these subscribers could not, and would not, exercise any influence whatsoever over the Congress. Though so much has been said in America about "graft," municipal corruption, and venal practices generally, the cause of science does not attract mere money hunters, the medical profession has always enjoyed the highest reputation and stands above suspicion. But it is frankly admitted that a great blunder has been committed. The meeting held at 5 o'clock on the Friday afternoon was not intended to be a hole and corner gathering. It was meant to be a formal, regular meeting of the entire International Committee. As, however, the foreign members knew that they would meet, according to the usual custom, at 10 o'clock on the Saturday morning they did not anticipate a convocation for 5 o'clock on the Friday afternoon, and would probably have had other engagements interfering with such a convocation. But they were not properly notified and did not go. There were present, I am told, only the representative of Canada, Professor Koch from Germany, Dr. von Schrötter from Austria, and the Chilian representative. Obviously this was not enough to constitute a quorum of the International Committee. Any conversation held should have been considered as informal, and, of course, so unrepresentative a gathering should have shrunk from the responsibility of interfering with the well-established procedure of international congresses, particularly as many of those who were present had had no experience of such congresses. On the Saturday morning when the International Committee really met and there was a full quorum, the violent protests that arose soon convinced those who had assisted at the abortive meeting of Friday afternoon that they had committed a serious mistake. Those who on the Friday had been in favour of suppressing all the resolutions carried in the sections now felt that it would be better to resuscitate them. That being so, the committee should have proceeded in the usual manner and appointed persons to read out to the Congress the text of the resolutions that had been adopted by the sections. Instead of this it drew up a sort of omnibus resolution which was supposed to summarise what had been done in the sections, but which, of course, had never been seen or voted upon by anyone. With the exception of the emphatic pronouncement on the question of bovine tuberculosis this resolution consists of an appalling collection of platitudes, and when compared with the resolutions carried at Paris three years ago can only be qualified as a retrograde step. On the other hand, some of the resolutions adopted in the sections were a distinct advance on what had been done on previous occasions, and therefore it is natural that their suppression should occasion keen disappointment.

From this long story of muddle and of misunderstanding the moral stands forth quite clearly. Every civilised State should have in its annual budget a sum set aside for the advancement of science. This sum should suffice, among other things, to enable each State in its turn to entertain the more important international scientific congresses. Invitations from countries where this is not done as a matter of principle should be refused. To obtain private subscriptions for congresses that are of national and international benefit should not be necessary. It is the duty of Governments to attend to such vast interests, and, in respect to these great international congresses, many Governments have already

---

So it seems as if the question of beer being good or bad for people at Christmas time depends very much on social position. This gentleman could not deny that many of the inmates were in the workhouse owing to a liking for strong drink and that it was undesirable to reintroduce beer to them. He paid, by the way, a somewhat ambiguous compliment to the officers by saying that they had not brought their condition to that of the paupers "up to the present." A lady guardian said that the inmates expressed themselves as satisfied without beer. The amendment to give them beer was rejected and probably, on the whole, wisely. But it is a curious position for the guardians to have the tea-pot on one side and the beer barrel on the other. They, however, stand on a higher plane.

Overhead Telegraph Wires.

The various committees of the Manchester City Council do not always see eye to eye. The city is already well supplied with overhead wires, too well by far, but there is a danger of still more being added to the hideous and dangerous network that threatens us in the principal streets. A long discussion took place the other day at a meeting of the highways and paving committee in regard to an agreement entered into between the watch committee and the Postmaster-General granting leave to the latter to erect telegraph posts in certain streets of the city. When first this proposal came before the council it was rejected by a large majority. Under the new agreement the watch committee seemed to think that the difficulty had been got over by giving the poles "a double debt to pay," and arranging that they should serve the purpose of bearing the telegraph wires and also those connected with the Gammell fire alarm system which the corporation has decided to adopt. The highways committee is practically unanimous in opposing the scheme and passed a resolution that no poles should be erected and that all wires connected with the Gammell system should be put under ground, or attached to the tramway standards, so now there is a prospect that the further disfigurement of our none too beautiful streets may be prevented. Besides being a disfigurement, these overhead wires are a dangerous nuisance. It is to be hoped that the opposition to the scheme will be successful.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

University College, Cardiff, Medical School.

THE increasing number of students entering the medical department of the University College of South Wales and Monmouthshire at Cardiff is seriously taxing the limited accommodation provided for them. The College buildings consist of a three-storey stone building which was originally the Cardiff Infirmary, supplemented by wood and iron structures which have been erected from time to time as they were required. The medical school is provided for on the topmost storey of the main building where there are two lecture theatres, a dissecting-room, a museum, and a room for practical histology and practical physiology. In the department of physiology Professor J. B. Haycraft has found great difficulty in carrying on his work to the best advantage owing to the lack of accommodation for demonstration purposes. In a letter which he recently sent to the College council asking that some steps should be taken to lessen the difficulties of teaching in such cramped quarters, he pointed out that the number of medical students entering the Cardiff College was greater than in any other provincial school except Cambridge and that the number was exceeded in only three of the London schools. The council will be well advised if it makes the necessary provision asked for by Professor Haycraft with as little delay as possible.

Water-supply of Glamorgan.

The Glamorgan county council has realised almost from the time of its formation that the provision of an adequate supply of water was a question of serious concern and one with which the council would have ultimately to deal. The question has grown more and more urgent in recent years owing to the rapid growth of the colliery districts and to the necessity for obtaining a supply well outside the coal-field. The council promoted a Bill in the last session of Parliament to empower the council to make inquiries and surveys with a view to the utilisation of water-supplies in South Wales and to form water districts and for other purposes. The power to form water districts was not conceded by Parliament, but the council was fully empowered to make inquiries and surveys and this power has been sufficiently utilised to justify the council in promoting a Bill in the next Parliamentary session having for its object the preservation of water areas for the benefit of various districts in the county and the formation of a water board which it is intended should include representatives from the local sanitary authorities. It is proposed in the Bill that the board should buy up the existing sources of supply of all the areas within the administrative county. The three county boroughs within the county, Cardiff, Swansea, and Merthyr Tydvil, are already well supplied with water for their present needs and the Cardiff corporation is actively engaged in securing a sufficiency for the anticipated increase in the population of the town. The county water board will keep in its own hands the sources of supply and the reservoirs and will supply the water in bulk, at a maximum charge of 4½*d.* per 1000 gallons, to the local authorities who will have the control of the distribution within the areas of their administration. The principal undertakings which it is intended to purchase are those of the Pontypridd Water Company and of the Rhymney and Aber Gas and Water Company. The former has a storage reservoir of 200 million gallons from which supplies are delivered to a portion of the Rhondda valleys, the town of Pontypridd, and to portions of the urban district of Caerphilly.

Damages against a Cardiff Hairdresser.

A Cardiff lady has obtained damages to the amount of £41 against a hairdresser in the town in circumstances which are fortunately of somewhat rare occurrence. While having what was styled a "brightening shampoo" she declared that the wash which was being used burned her head, took away her breath, and made her eyes water, and that subsequently her hair changed colour and broke off both at the roots and at the ends. Medical evidence was given on behalf of the hairdresser in support of his contention that the condition described by the lady was not due to the wash which was used, but in the end, as already stated, the county court judge gave judgment in her favour.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh and Leith Medical Practitioners' Association.

THE inauguration of this association was referred to some weeks ago. It has now concluded its first attempt to deal with public questions affecting practitioners and the results are deserving of note. Dr. Alexander James read a paper before the association on the relations of the practitioner and the public health authorities. In this paper the development of the medical officer of health and of the inspecting officer in board schools was traced. In both cases the object was to protect the community as a whole from disease to which they were exposed as the result of the aggregation of individuals in communities and in schools. He emphasised the fact that the medical man was an expert whose opinion the public were not in a position to judge of and that it was, as a consequence, of the utmost importance that the medical advice should not lead to responsibilities and burdens being laid on the community when they ought to be left on the shoulders of the individual. This proposition was preliminary to Dr. James expressing the opinion that an impartial examination of the health statistics of the last 25 years showed that public health enactments had not been followed by the improvement which the public had been led to expect, and that in certain cases harm had resulted therefrom. He thought that at the present time what was desirable in the public interest was a lessened rather than an increased interference on the part of the public health authorities in the ordinary relations between the public and the medical profession. In conclusion, he suggested that the association might be asked to give its opinion on each of the three following points: (1)

when the first dressing was changed, usually after a week, the wound had healed. If, however, for the purpose of investigation one dresses such wounds early, one obtains a negative result as regards the presence of bacteria in their interior. Further, in cases where as the result of leaving too large a cavity or from some other cause serum accumulates in the wound, one may find on evacuating it even after a week or more that it does not contain organisms. As a practical fact, therefore, we may take it that organisms do not grow in wounds treated by strict Listerian precautions.

But can we say that living bacteria do not gain access to wounds at the time of the operation and are not present there in a living state when the wound is closed? It is quite probable that in the earlier methods of treatment, such as the application of undiluted carbolic acid, the bacteria were all destroyed, and no living organisms were left in the wound. But that can hardly be the case in the later developments of the Listerian method, especially in the plan which is so much the fashion now—namely, the so-called aseptic method. No doubt the entrance of living organisms during the operation from external objects such as the skin, the instruments, the ligatures, &c., can be prevented, but their entrance from the air can not. We know that air in a state of motion is full of dust, and if we expose plates covered with nutrient jelly to such air we find that various spots of growth appear on the surface, their number and the character of the organisms which compose them varying according to the length of time the plates are exposed, to the place where the exposure is made, and to the moisture of the atmosphere. Why, then, are these organisms not found in the discharge contained in the wound after 24 hours?

This raises a very wide question. If organisms do not, as a rule, grow in a wound when the only loophole for their entrance is the air, why is it that they so constantly grow in wounds when no antiseptic precautions have been taken and where other loopholes have therefore been left open? This depends, in the first place, on the kind of organism which enters. If plates covered with nutrient jelly are exposed in an ordinary dry atmosphere, the great majority of organisms which develop are moulds or various kinds of bacilli. As a matter of fact, the chief living contents of the dust of the air are spore-bearing organisms, for non-spore-bearing organisms, such as the micrococci, cannot withstand drying and soon lose their vitality when deprived of moisture. We may therefore assume that the fungi and bacilli which are ordinarily present in the atmospheric dust are unable to grow in the living tissues of man; in other words, are not pathogenic in man, at any rate under the conditions present in a wound treated by strict Listerian methods.

The chief habitat of the pyogenic cocci so far as infection of wounds is concerned is the skin of the patient or the operator or discharges from wounds which may be present in the neighbourhood of the seat of operation. Where, therefore, the skin of the patient and the hands of the operator are thoroughly disinfected, and where precautions are taken which prevent further contamination, the probabilities are that there are many wounds into which no pyogenic cocci have entered and where the only organisms which fall in are non-pathogenic to man. Nevertheless one does find cocci closely related to the pyogenic ones and sometimes actually belonging to that class in atmospheric dust, especially where the air is moist, and in a prolonged operation it is highly probable that organisms of that class also fall into the wounds and yet they do not grow. Hence, we must consider the other possibilities.

Early in the development of bacteriology it was shown that pathogenic power was a property which varied very markedly and which could be impaired by a variety of comparatively slight causes; among others, the use of various antiseptic substances in a dilution short of that required to kill micro-organisms was found to diminish their pathogenic activity. For example, among the various ways in which the virulence of the anthrax bacillus can be diminished or "attenuated," as the French expression is, one is the action of weak solutions of carbolic acid on the organisms for varying periods of time. Hence, when, as already stated, I found micrococci in the discharges from wounds which were following an aseptic course, in the old days of carbolic gauze and the freer use of carbolic lotions, I thought that the explanation might be that the virulence of the organisms had been diminished by the action of the carbolic acid, and the same may have been the case with cocci coming from the air in the old days of the carbolic spray. This, however, though a plausible explanation, did not seem to me on more careful consideration to be altogether sufficient to explain the facts.

On thinking further over these matters it occurred to me to inquire whether the number of bacteria which entered the body at any one time was of importance and whether this might explain the improved results of those who had not fully adopted the Listerian treatment but who, nevertheless, tried to be as cleanly as possible—that is to say, who introduced as few bacteria as possible into their wounds. The fact already demonstrated by Lister that, in order to produce putrefaction in blood clot in glass vessels, it was necessary to add a definite, though small, quantity of putrid material, and the statement that good results were obtained by simply washing the hands and skin with soap-and-water, in operations on the peritoneum especially, seemed to make it worth while to try a few experiments on the subject. The result showed that the number of bacteria which initiate the disease is in certain cases of paramount importance, and this has now become one of the fundamental bacteriological facts. In only very few cases was a single bacterium able to start disease; in most instances several were necessary, while in some large numbers were required. Thus in the case of anthrax and mouse septicæmia one bacterium was apparently sufficient to start the disease in guinea-pigs and mice respectively, while in the case of rabbits several anthrax bacilli were required. In the case of tetanus no result followed the introduction of less than 1000 bacilli into rabbits. With somewhat larger doses a local tetanic spasm of the limb inoculated occurred from which the animal recovered, while larger numbers caused death, till 40,000 and over killed the animals in two days. In the case of pyogenic cocci in rabbits the numbers required to produce disease were very much larger, something like 100 to 300 million being required to produce an abscess, and 1000 million to cause death. The results, of course, vary with the species of animal tested; in other words, with the susceptibility of the animal to the action of a particular organism. Among other conclusions arrived at the following may be mentioned as bearing on our subject: (1) The pathogenic dose of a virus varies inversely with the predisposition of the animal to the disease in question; and (2) in animals not very susceptible to a disease, the severity of the affection varies directly within certain limits with the amount of the virus introduced in the first instance. The same facts apply according to the virulence of the organism. Where the organism is in a high state of virulence a smaller number will be required to produce the effect in a suitable animal than where the virulence is what we may term normal; and, conversely, if the virulence is diminished a larger number of organisms will be necessary. As regards the pyogenic organisms in man, I came to the conclusion that man was not a particularly susceptible subject for the growth of these organisms, and that, therefore, a considerable number were required to produce a pathogenic effect.

Thus we have three reasons why wounds treated on Listerian principles are found to be free from organisms, even although it is certain that organisms of some kind or other do enter during the operation. 1. No pathogenic organisms are admitted at the time of the operation; this is probably so in most instances. 2. If pathogenic organisms do enter they may be so few in number that they cannot obtain a footing. 3. The pathogenic organisms which enter may have such slight virulence, either naturally, or acquired as the result of the action of the antiseptics with which they come in contact, that they cannot overcome the resisting power of the body. As a matter of fact, the organisms which usually enter during a carefully performed Listerian operation are either non-pathogenic bacilli or the ordinary micrococcus epidermidis which has only very slight, if any, pathogenic power.

2. Let us now refer in the second place to the effect on the tissues of the methods employed to prevent bacteric infection. In the treatment of wounds we must not concentrate our whole attention on the exclusion of bacteria. We must also avoid irritation of the tissues exposed in the wound as far as possible. I have already referred to this matter and to the results which may follow as regards the healing of wounds from too great irritation. The question here is how far the measures necessary to prevent bacteric infection do

forthcoming from all directions that the apostolic methods of itinerant instruction in hygiene and sanitation which have developed so auspiciously in association with, and in the wake of, the anti-tuberculosis crusade are already producing fruit.

Completion of Waterworks and Main Drainage System of Howth.

A new epoch in the sanitary and general hygienic progress of the picturesque locality of Howth has just been ushered in by the completion—and "expert inspection"—of the works designed for the water-supply and drainage of this very ancient village. The scenery and surroundings of Howth have ever proved specially attractive to foreign visitors, and while the electric tramway has made it a convenient suburb of Dublin its wireless telegraph station has given it a privileged position in relation to the distant centres of the world. A remarkable fact in the history of the development of recent Irish industrial activity is that the contract has been completed within a period of nine months less than the stipulated time. This is the more noteworthy as cliffs and crags had to be continuously negotiated; and steam drills, "American shovels," and the whole battalion of instruments of engineering warfare with the strongholds and fastnesses of nature were actively utilised throughout the whole proceedings. Also, ten fountains have been provided in the village and there are 50 hydrants which are placed in the various positions in which danger to property from fire might be anticipated. A circular has been sent out to the householders of Howth (by the contractors, Messrs. McKee and McNally) notifying to them the completion of the waterworks and intimating that connexion should be made forthwith for utilisation of the same. There is every reason to believe that under the new conditions Howth will become one of the healthiest localities within the British Islands.

Health of Belfast.

At a meeting of the city council held on Dec. 1st it was reported that for the period from Oct. 25th to Nov. 21st the death-rate was 17·0 per 1000. 38 cases of enteric fever were notified, as compared with 32 in the corresponding period of 1907. In four instances the milk-supply was from the same source, a supply which was promptly dealt with, in order to prevent any danger from further infection. The Local Government Board has asked the council for payment of £1431 10*s.* 10*d.*, the expenses of the Health Commission, less £500 Treasury grant towards the same, and the council has replied repudiating any liability in the matter, but saying that it was prepared to offer, without prejudice. to pay £1431 10*s.* 10*d.*, less £608 0*s.* 3*d.*, the expenses of the chairman, Colonel Harding, D.L., Dr. L. W. Darra Mair, and Dr. A. K. Chalmers.

The Abbey Sanatorium, Belfast.

Mr. Robert Hall (physician to the Abbey Sanatorium for Pulmonary Tuberculosis) has presented to his committee a most interesting report of the half year ending Sept. 30th, 1908. During this period 568 patients were treated, of whom 303 left the institution, thus leaving 265 still under treatment. Of those who left 201 were males and 102 were females, and of the total 35 were greatly improved, 165 were improved, 35 were not improved. and 68 were for too short a period in hospital or died. The general average age in years of the above was 30—32¾ for males and 27⅓ for females. The average duration of time in days in the sanatorium was 115½—117 for males and 114 for females. As to occupation among the females, the largest number were housekeepers and spinners, while among the men labourers were by far the largest class. Mr. Hall urges very strongly the necessity of patients entering in an early stage of the disease, and he gives preference for sanatorium treatment to those patients in an early stage. Despite the fact that there are 265 beds in the sanatorium, he has still 85 consumptive patients in the union infirmary who cannot be received in the Abbey owing to want of space. Additional buildings at the sanatorium are becoming daily more urgently needed. All discharges from the Abbey are notified to the public health department, so that the medical officer of health may look after them. Those of the patients who are able are employed in various light occupations, the work in all classes being regulated by the medical officer. The average cost per week of each patient was 11*s.* 8¼*d.*, or if all other charges—viz., establishment, burial, law, repayment of loan, &c.—be added, 16*s.* 9½*d.*, which is remarkably small. The board of guardians of Belfast and its efficient medical officer, Mr. Hall, who was the first Poor-law infirmary medical officer in Ireland to isolate consumptives in a union infirmary, are to be congratulated warmly on the Abbey Sanatorium which is an object-lesson to the rest of Ireland.

Sir Robert Hart, Bart., G.C.M.G.

During the past week one of the most distinguished living Ulstermen has been revisiting his native home and has been most cordially welcomed. As an old student of Queen's College, Belfast, Sir Robert Hart was enthusiastically received on the afternoon of Dec. 2nd, when he was presented with an address, and on the next evening he was entertained at a banquet at the College. In reply to the toast of his health Sir Robert Hart gave a most interesting account of his work in China.

The Queen's University of Belfast.

At the first meeting of the Senate held in Queen's College, Belfast, on Dec. 4th, Sir Robert Hart, Pro-Chancellor, presided in the place of the Chancellor, the Earl of Shaftesbury, who was unable to be present. The charter of the University having been laid on the table, an executive committee (to carry out the details rendered necessary in connexion with the getting into working order of the University) and a building committee (to inquire what additional buildings are required, to obtain plans for same, with estimates of cost, and to report through the executive committee to the Senate) were appointed. It was agreed to insure the college buildings.

Municipal Elections in Belfast.

The coming elections for the city council, Belfast, in January are likely to be contested sharply, and in most cases the health question is being made a test one. In Ormeau ward Alderman J. D. Williamson, M.D. R.U.I., chairman of the police committee, and in St. George's ward Dr. Henry O'Neill, chairman of the markets committee, are going forward for re-election. They have each in their separate departments done good work.

Outbreak of Enteric Fever in Co. Leitrim.

An alarming outbreak of enteric fever has occurred in the Glenfarne district, there being 50 cases in hospital. Dr. B. A. O'Flynn, acting medical officer of health, in a report to the Manorhamilton district council on Nov. 5th, said he was forced to the conclusion that the alarming proportions which the epidemic had assumed were undoubtedly due to infection by separated milk. The Local Government Board has urged the necessity of putting into force the Dairies and Cowsheds Order and appointing a competent veterinary surgeon. This latter advice was acted on and it was decided to appoint such an official.

Dec. 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Hot-air Douche.

M. Dausset and M. Laquerriére communicated a paper at a recent meeting of the Society of Medicine which dealt with the cases of 70 patients treated by a rapid current of hot air, a method which seemed to them superior to other ways of applying heat for the production of hyperæmia. They were able to confirm the good results already obtained by other observers in such diseases as neuralgia. rheumatism, eczema, and hydrarthrosis, and they endeavoured in their paper to define the indications for this method of treatment. Finally, they claimed to be the first to have made observations with regard to this method in the conditions hereinafter mentioned. In suppurating wounds the hot-air douche rapidly brings the suppuration to an end and causes cicatrisation. In cases of stiff joints the periarticular œdema is absorbed and the hot air causes an analgesia which permits of the joint being moved from the first. In chronic cases of radio-dermatitis the itching disappears while the atrophy of the skin is much improved. M. Borns asked whether the treatment had been used in sciatica. M. Laquerriére replied that he had found it give good results in cases of simple sciatica if

mercurial preparations, and thus protect the bacteria in the interior for a long time. Carbolic acid, however, can penetrate this coagulum and even under these circumstances will, as a rule, lead to complete destruction of the bacteria and their spores in 24 hours. It is well to recall these facts, for the extremists seem to forget that antiseptics can do what is asked of them and that heat is not the only way of destroying bacteria. It is not really necessary to try to devise elaborate methods of sterilising materials such as catgut by heat, or to discard the use of valuable articles such as marine sponges because they are spoilt by boiling. Immersion in suitable antiseptic solutions for the appropriate length of time will be thoroughly effectual in these cases.

As regards the fourth point, I believe that the extreme aseptic-views have sprung up to a large extent from the statement that it is practically impossible to disinfect the skin. I confess that these statements puzzle me very much, bearing in mind the uniformly aseptic results which we have for years obtained without the use of gloves—results which have not and cannot be improved upon. In the absence of organisms from our wounds and the aseptic course they pursue it is difficult to believe that the skin has not been thoroughly disinfected. Some time ago I went over all the various points in the technique to see how far we were working under bacteria-free conditions, and the ordinary methods of disinfection of the skin seemed quite satisfactory, except in a few situations such as the axilla and the perineum. My plan was to disinfect the skin with antiseptics in the ordinary way and then to flush the part carefully with sterilised water so as to remove the antiseptic; then to scrape the skin so as to obtain the epithelium and to implant that into tubes of suitable material. The conclusion I arrived at was that there was no difficulty in disinfecting the skin except in the situations I have mentioned. In the case of children and in parts of the body where the skin was thin the disinfection seemed to be thorough and rapid. I was therefore at first very much surprised at the statements as to the difficulty of disinfecting the skin. These statements rest on a different method of testing the matter than that which I adopted—namely, a piece of the whole thickness of the skin is taken instead of a mere scraping of the surface, and it is assumed that the organisms lie in the deeper layers of the epithelium and in the sweat and sebaceous glands, and thus escape the action of the antiseptics. It is very difficult, however, to believe that organisms inhabit the sebaceous and sweat ducts and glands without causing trouble; besides, we must also assume that these canals differ from others, such as the healthy urethra, along which organisms seem unable to penetrate for any distance. It may also be pointed out that this method of testing the matter is more open to the risk of contamination than that of taking the epithelium alone, and also that much depends on the methods of disinfection employed. I believe it is essential to employ carbolic acid for the disinfection of the skin. It mixes with the fatty material and penetrates through the epithelium in a way that no other antiseptic does. Mercurial solutions are very inefficient as they do not mix with fatty material, and thus do not penetrate the epidermis. Even after washing the skin thoroughly with etherial soap the mercurial solution collects in drops like water on a duck's back, while carbolic lotion wets the skin uniformly. In many of the experiments mercurial preparations have apparently been the antiseptic employed. In any case, however, I would maintain that my method of experimentation is the better test and more in accordance with the practical technique.

Fifthly, these views as to the inefficiency and harmful action of antiseptics have coincided with an increased belief in the resisting power of the tissues to bacteric invasion, and in the minds of some it has seemed of even greater importance to try to keep up or to increase the resisting power of the tissues than to destroy the bacteria. The importance of this point was early realised by Lister and has not been lost sight of and there is no doubt that every care must be taken to interfere as little as possible with these protective agencies. It is, however, really a question of relative importance, and I believe that where we have to do with an operation through unbroken skin the most important point is to prevent the entrance of bacteria. Experience amply shows that this can be done as far as is necessary without materially damaging the resisting power of the part. On the other hand, where the operation is performed in regions such as the mouth, where bacteria are present and cannot be excluded, while fresh contamination should of course be avoided, the chief reliance must be placed on the resisting power of the tissues, and everything which may to any extent diminish that must be avoided. At the present time the subject of resisting power is still in the stage of development, and in any case ample clinical experience has shown us that we must not place too great reliance on this factor.

Let us now see how far the methods of wound treatment at present adopted meet the requirements of the case. Of late many surgeons have gone to extremes in the avoidance of antiseptic solutions and speak of the plan they use as "aseptic surgery." This term "aseptic surgery" is in my opinion not a good one. It is looked on by some as implying a different principle to the Listerian one, but, of course, that is not the case. It is only carrying to an extreme the principle of avoiding irritation of wounds and giving Lister's second postulate a position of undue prominence. It is fortunately only a few surgeons who misread the facts to such an extent as to give up any attempt at excluding bacteria and depend upon what is popularly known as cleanliness. These use water boiled or unboiled, sometimes not even adding chloride of sodium to it, and are thus under the happy delusion that they are using materials which will not interfere with the normal resisting mechanism of the body. But so far as that mechanism depends on the integrity of leucocytes and other cells in the wound they might as well, or even better, use antiseptics; for one has only to watch the behaviour of these cells under the microscope, on the addition of plain water, to see how rapidly they swell up and become completely disintegrated. I used the term "aseptic surgery" many years ago to indicate Listerism, with the meaning that the wound was kept aseptic, as opposed to "antiseptic surgery," where attempts were made to eradicate sepsis from wounds already infected. At the present time "aseptic surgery" is used to indicate the character of the materials used rather than the result of the procedure. I confess I do not like this use of the term and prefer my own. By all means speak of "aseptic dressings," but in speaking of aseptic surgery we ought, I venture to assert, to refer to the results of the method rather than to the materials employed. Even the term "aseptic treatment" is not quite accurate if it implies treatment without antiseptics, for the disinfection of the skin cannot be carried out without antiseptics. As a matter of fact, however, it is only in certain details that differences exist between those who still adhere to the full Listerian views and those who go to extremes in the avoidance of chemical antiseptics. For my own part, I still adhere to the moderate party—if I may so term it—and consider that antiseptics should not be discarded altogether, but that their judicious use is advisable and important.

Three things have to be borne in mind in connexion with an operation. In the first place we have to see that the skin of the operator and the patient is as thoroughly disinfected as possible, and that no instrument or other article which comes in contact with a wound is soiled with living bacteria; in the second place, we have to avoid accidental infection of the wound during the operation; and in the third place, we have to avoid infection of the wound subsequent to the operation.

As regards the *first point*, we have to consider the disinfection of the chief things which must of necessity come in contact with the wound, and more especially the disinfection of the skin of the patient in the region of the operation and of the surgeon's hands and arms, for the chief source of contamination of wounds with pyogenic organisms is no doubt the skin of the patient and of the operator. I do not think that there is any real divergence of views as to the necessity for this procedure, and there is general agreement that this can only be satisfactorily carried out by the use of antiseptics. No doubt there are considerable differences in the methods of disinfecting the skin, but I need not go into them. It is true also that a few surgeons are content with rinsing the skin of the patient and of their own hands in boiled water, but I fancy that most will agree that that does not meet the requirements of the case.

In addition to the disinfection of the skin a good many surgeons take the precaution of wearing gloves in case the disinfection of the hands has been imperfect; indeed, some

you or your assistant ever receive a fee from a chemical factory either for making an experimental or a clinical trial of a compound? If so, was the fee received for your personal benefit or for some charitable institution connected with your hospital? If not, do you think it proper to accept such a fee? The opinions given by the medical men in question have varied considerably. Professor Curschmann of Leipsic wrote that he never tried compounds for, or gave a certificate to, a chemical factory. He publishes reports in the medical press exclusively and expressly forbids chemical manufacturers to circulate copies of these reports as advertisements. Professor von Noorden, on the other hand, declared that he had often stipulated with chemical factories that they should pay a certain sum to some charitable institution for the trial of compounds. One half of the sum was to be paid before the trial began and the other half only when the trial was successful; but he had never accepted a fee for his personal use. Professor Ehrlich of Frankfort said that a distinction must be made between the trial of compounds on patients and experiments in laboratories. The latter entail heavy expenses and he considers that it is only fair for chemical factories which derive so much advantage from these experiments to bear at least a portion of the expenses. The Union of the Medical Press was not unanimous on the subject but finally the majority agreed that whilst it was in the interests of medical science that new compounds should be thoroughly examined by competent authorities, the respective experiments entailed so much time and sometimes expense that it would be unjust to forbid those who undertook them to receive fees for their work. The editors of medical journals were, however, asked to insert no articles concerning compounds which are not by responsible authors and to reject any article which bears a trace of partiality. Authors of such articles will be put on the "black list" according to the decision passed at the last meeting of the Union of the German Medical Press.[1]

Paying Wards in Municipal Hospitals.

Some members of the municipal council have put down a motion proposing the erection of paying wards for the better-class patients in the municipal hospitals similar to the wards which exist in other hospitals. The medical press objects to this proposal. It is said that in the non-municipal hospitals (which in Berlin for the most part belong to religious corporations) the fees paid by the better-class patients are just sufficient to cover the expenses of the patient's stay in the hospital, but that the hospital physicians and surgeons who attend these patients do not receive a farthing from the sum paid by them. If these patients were received into a private sanatorium they would have to pay not only higher fees for their board and lodging but also fees to their medical attendant, and as they belong as a rule to the well-to-do classes there is no reason to give them facilities for gratuitous medical attendance. The system obtaining in the hospitals belonging to religious and other corporations has always been resented by the medical profession because it prejudices their private practice and there is no need to extend it to the municipal hospitals. Well-to-do patients desiring to have their home comforts during their illness should be treated in private nursing homes, which are abundant in Berlin, and not in municipal hospitals supported by the ratepayers. The beds occupied by the proposed paying wards had better be devoted to ordinary patients, especially as the existing number of beds at certain times of the year is not sufficient to meet the requirements. In every case the medical staff ought to be allowed to recover fees from their patients. This motion has not yet been discussed and it is to be hoped that the council will not agree to it.

Sunshine in the Treatment of Surgical Tuberculosis.

Dr. Oscar Bernhard of St. Moritz in the Engadine has just published his experiences of many years on the therapeutic influence of sunlight in the treatment of simple and infected wounds, ulcers, tuberculosis of the skin, glands, joints, and bones, of cancer of the skin, and deep-seated syphilitic ulcerations. In a great number of such cases sunshine directly applied was of great help in determining a cure. A number of good illustrations prove this point. The high altitude (1800 metres, or 6000 feet, above the sea level) increases the beneficial effect of the sunlight treatment, and the excessive dryness of the air must also take some part in it. The active hyperæmia produced by the rays of the sun doubtless assists in the process of healing. The bactericidal effects of sunshine were proved by Downes and Blunt (Proceedings of the Royal Society of London) so far back as 1877. Dr. Bernhard employs pliable metallic funnels to treat fistulæ of different sizes and depth. He refers to the good results which Dr. Rollier has obtained by heliotherapy. In the *Revue Médicale de la Suisse Romande* of Sept. 20th, 1907, Dr. Rollier reports about 110 cases of surgical tuberculosis treated since 1903 at Leysin (altitude 1450 metres = 4800 feet), above Aigle in the canton of Valais, in his clinique on lines developed by Dr. Bernhard. Operative interference was reduced to a minimum and the results obtained were most gratifying. Dr. Rollier publishes ten new cases of complex tuberculous disease of joints and bones treated with remarkable success.

A Zürich League against Consumption.

On Nov. 29th at a meeting in the town-hall of Zürich, which was attended by more than 300 persons of both sexes, a cantonal league against tuberculosis was founded. Dr. Staub, physician of the canton of Zürich sanatorium at Wald, spoke on medical measures for fighting this dire disease which still annually causes some 4500 deaths in Switzerland, the rate of mortality being 18 in 10,000. Pastor Reichen of Winterthur enlarged on the social dangers and financial losses caused by the "white plague." Mrs. Corradi-Stahel referred to antituberculous educational methods in family life, whilst Dr. Hauser, president of the Cantonal Medical Society, gave full details about the present and future programme.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Emmanual Movement.

THE medical profession and the public are agitated over the introduction into the practice of medicine of what is called "The Emmanual Idea," which had its origin in the Emmanual Church of Boston of which the Rev. Dr. Worcester is rector. The rector recently explained the origin of the Emmanual method to a New York audience composed largely of clergymen, physicians, and "Christian Scientists," the object of the lecture being to establish clinics in connexion with churches for the treatment of diseases by this method in this city, on the plan of the clinic in operation in the Emmanual Church of Boston. The rector stated that seven years ago he and Dr. S. Weir Mitchell of Philadelphia, the well-known specialist in nervous diseases, were discussing the growth of "Christian Science" and the latter suggested that they should together evolve a system which would be adapted to present conditions. After years of thought the rector finally evolved the idea which, after consulting "one of the best known physicians" of Boston, was worked out by him and his assistants in the Emmanual Church. He stated that "one of the most eminent physicians of New England" had come down to start the work and other members of the medical faculty are now working with the clergy in the clinics. He added that since the work was begun 2200 persons had been treated and many had been greatly benefited, while none had committed suicide. The method of treatment is that of suggestion. Already the "Emmanual Idea" has found great favour with the episcopal clergy of New York and has been publicly approved by several of the most prominent specialists in nervous affections. A clinic is about to be established in connexion with St. Mark's Church, one of the oldest episcopal churches in the city, and St. George's Church is likely to organise another clinic.

The Army Medical Department.

The Surgeon-General of the Army, Dr. O'Reilly, has issued his report and on Jan. 14th next will retire, having

mercurial preparations, and thus protect the bacteria in the interior for a long time. Carbolic acid, however, can penetrate this coagulum and even under these circumstances will, as a rule, lead to complete destruction of the bacteria and their spores in 24 hours. It is well to recall these facts, for the extremists seem to forget that antiseptics can do what is asked of them and that heat is not the only way of destroying bacteria. It is not really necessary to try to devise elaborate methods of sterilising materials such as catgut by heat, or to discard the use of valuable articles such as marine sponges because they are spoilt by boiling. Immersion in suitable antiseptic solutions for the appropriate length of time will be thoroughly effectual in these cases.

---

[1] See THE LANCET, August 17th, 1907, p. 483.

As regards the fourth point, I believe that the extreme aseptic views have sprung up to a large extent from the statement that it is practically impossible to disinfect the skin. I confess that these statements puzzle me very much, bearing in mind the uniformly aseptic results which we have for years obtained without the use of gloves—results which have not and cannot be improved upon. In the absence of organisms from our wounds and the aseptic course they pursue it is difficult to believe that the skin has not been thoroughly disinfected. Some time ago I went over all the various points in the technique to see how far we were working under bacteria-free conditions, and the ordinary methods of disinfection of the skin seemed quite satisfactory, except in a few situations such as the axilla and the perineum. My plan was to disinfect the skin with antiseptics in the ordinary way and then to flush the part carefully with sterilised water so as to remove the antiseptic; then to scrape the skin so as to obtain the epithelium and to implant that into tubes of suitable material. The conclusion I arrived at was that there was no difficulty in disinfecting the skin except in the situations I have mentioned. In the case of children and in parts of the body where the skin was thin the disinfection seemed to be thorough and rapid. I was therefore at first very much surprised at the statements as to the difficulty of disinfecting the skin. These statements rest on a different method of testing the matter than that which I adopted—namely, a piece of the whole thickness of the skin is taken instead of a mere scraping of the surface, and it is assumed that the organisms lie in the deeper layers of the epithelium and in the sweat and sebaceous glands, and thus escape the action of the antiseptics. It is very difficult, however, to believe that organisms inhabit the sebaceous and sweat ducts and glands without causing trouble; besides, we must also assume that these canals differ from others, such as the healthy urethra, along which organisms seem unable to penetrate for any distance. It may also be pointed out that this method of testing the matter is more open to the risk of contamination than that of taking the epithelium alone, and also that much depends on the methods of disinfection employed. I believe it is essential to employ carbolic acid for the disinfection of the skin. It mixes with the fatty material and penetrates through the epithelium in a way that no other antiseptic does. Mercurial solutions are very inefficient as they do not mix with fatty material, and thus do not penetrate the epidermis. Even after washing the skin thoroughly with etherial soap the mercurial solution collects in drops like water on a duck's back, while carbolic lotion wets the skin uniformly. In many of the experiments mercurial preparations have apparently been the antiseptic employed. In any case, however, I would maintain that my method of experimentation is the better test and more in accordance with the practical technique.

Fifthly, these views as to the inefficiency and harmful action of antiseptics have coincided with an increased belief in the resisting power of the tissues to bacteric invasion, and in the minds of some it has seemed of even greater importance to try to keep up or to increase the resisting power of the tissues than to destroy the bacteria. The importance of this point was early realised by Lister and has not been lost sight of and there is no doubt that every care must be taken to interfere as little as possible with these protective agencies. It is, however, really a question of relative importance, and I believe that where we have to do with an operation through unbroken skin the most important point is to prevent the entrance of bacteria. Experience amply shows that this can be done as far as is necessary without materially damaging the resisting power of the part. On the other hand, where the operation is performed in regions such as the mouth, where bacteria are present and cannot be excluded, while fresh contamination should of course be avoided, the chief reliance must be placed on the resisting power of the tissues, and everything which may to any extent diminish that must be avoided. At the present time the subject of resisting power is still in the stage of development, and in any case ample clinical experience has shown us that we must not place too great reliance on this factor.

Let us now see how far the methods of wound treatment at present adopted meet the requirements of the case. Of late many surgeons have gone to extremes in the avoidance of antiseptic solutions and speak of the plan they use as "aseptic surgery." This term "aseptic surgery" is in my opinion not a good one. It is looked on by some as implying a different principle to the Listerian one, but, of course, that is not the case. It is only carrying to an extreme the principle of avoiding irritation of wounds and giving Lister's second postulate a position of undue prominence. It is fortunately only a few surgeons who misread the facts to such an extent as to give up any attempt at excluding bacteria and depend upon what is popularly known as cleanliness. These use water boiled or unboiled, sometimes not even adding chloride of sodium to it, and are thus under the happy delusion that they are using materials which will not interfere with the normal resisting mechanism of the body. But so far as that mechanism depends on the integrity of leucocytes and other cells in the wound they might as well, or even better, use antiseptics; for one has only to watch the behaviour of these cells under the microscope, on the addition of plain water, to see how rapidly they swell up and become completely disintegrated. I used the term "aseptic surgery" many years ago to indicate Listerism, with the meaning that the wound was kept aseptic, as opposed to "antiseptic surgery," where attempts were made to eradicate sepsis from wounds already infected. At the present time "aseptic surgery" is used to indicate the character of the materials used rather than the result of the procedure. I confess I do not like this use of the term and prefer my own. By all means speak of "aseptic dressings," but in speaking of aseptic surgery we ought, I venture to assert, to refer to the results of the method rather than to the materials employed. Even the term "aseptic treatment" is not quite accurate if it implies treatment without antiseptics, for the disinfection of the skin cannot be carried out without antiseptics. As a matter of fact, however, it is only in certain details that differences exist between those who still adhere to the full Listerian views and those who go to extremes in the avoidance of chemical antiseptics. For my own part, I still adhere to the moderate party—if I may so term it—and consider that antiseptics should not be discarded altogether, but that their judicious use is advisable and important.

Three things have to be borne in mind in connexion with an operation. In the first place we have to see that the skin of the operator and the patient is as thoroughly disinfected as possible, and that no instrument or other article which comes in contact with a wound is soiled with living bacteria; in the second place, we have to avoid accidental infection of the wound during the operation; and in the third place, we have to avoid infection of the wound subsequent to the operation.

As regards the *first point*, we have to consider the disinfection of the chief things which must of necessity come in contact with the wound, and more especially the disinfection of the skin of the patient in the region of the operation and of the surgeon's hands and arms, for the chief source of contamination of wounds with pyogenic organisms is no doubt the skin of the patient and of the operator. I do not think that there is any real divergence of views as to the necessity for this procedure, and there is general agreement that this can only be satisfactorily carried out by the use of antiseptics. No doubt there are considerable differences in the methods of disinfecting the skin, but I need not go into them. It is true also that a few surgeons are content with rinsing the skin of the patient and of their own hands in boiled water, but I fancy that most will agree that that does not meet the requirements of the case.

rofessor R. J. Kinkead of Galway. Dr. Allen was buried on ec. 4th, the funeral being strictly private.

SAMUEL HOPKINS STEEL, M.B. LOND., M.R.C.S. ENG., J.P.

Dr. Samuel Hopkins Steel died at his residence, Dyne ouse, Abergavenny, Monmouthshire, on Nov. 25th, in his ghty-eighth year. The deceased, who received his medical ucation at King's College Hospital, London, qualified .R.C.S. Eng. in 1843 and two years later graduated M.B. of e University of London. Dr. Steel was for many years in ractice at Abergavenny but retired from active work some ears ago. He was at the time of his death consulting sureon to the Abergavenny Cottage Hospital. He was for many ears medical officer of health of the Abergavenny urban disict and was on the commission of the peace for the county f Monmouth. He took a great interest in the Volunteer ovement and for some years was captain of the Abergavenny ifle Corps, then known as the 7th Monmouthshire. Dr. teel was one of the oldest and most respected inhabitants f Abergavenny and his funeral, which took place at lanfoist Churchyard on Nov. 30th, was very largely ttended.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths f the following foreign eminent medical men are nnounced:—Dr. Hermann Gutmann of Berlin, author of arious books on hygiene and diseases of children, aged 60 ears. Dr. Erdmann, medical councillor of Dresden.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following egrees were conferred recently:—

M.D.—C. H. W. Page, Corpus Christi; A. G. Harvey, St. John's; and R. N. Chopra, Downing.
M.B.—C. H. Rippmann, King's; H. H. Taylor, Pembroke; H. G. Fream, St. John's; F. P. Young, Christ's; J. B. Mennell, Pembroke; and J. F. Windsor, H. Selwyn.
B.C.—W. B. Marshall, St. John's.

Permission to incept in Surgery without examination has een granted to Dr. T. H. Kellock, Emmanuel College.—The office of Superintendent of the Zoology Museum becomes acant on Jan. 15th, 1909, by the resignation of Dr. Harman. The stipend at present is £200 per annum. Applications should be made to Professor J. N. Langley before Jan. 21st, 1909.—The following appointments have been made:—University Lecturer in Pharmacology: Professor W. E. Dixon. Members of General Board of Studies: Dr. W. H. Gaskell and Mr. A. E. Shipley. Member of Library Syndicate: Dr. H. K. Anderson. Members of State Medicine Syndicate: Professor Langley and Dr. W. L. H. Duckworth. Member of Special Board for Medicine: Dr. W. M. Fletcher. Member of Board of Geographical Studies: Dr. F. H. H. Guillemard. Member of Board of Military Studies: Dr. J. Griffiths. Examiners in State Medicine: Dr. B. Anningson, Dr. J. Niven, Dr. G. S. Graham-Smith, and Mr. J. E. Purvis. Examiners in Tropical Medicine and Hygiene: Dr J. W. W. Stephens, Dr. C. W. Daniels, and Lieutenant-Colonel W. B. Leishman.

UNIVERSITY OF LONDON.—At examinations held in October the following candidates satisfied the examiners:—

M.B., B.S. EXAMINATION.

Honours.—*§Herbert Orpe Brookhouse (University medal), Guy's Hospital; §Arthur Laurence Candler, St. Bartholomew's Hospital; ‡Maxwell Dick, University College Hospital; *Habibulla I. Jan-Mahomed, Guy's Hospital; §Austin Threlfall Nankivell and ‡James Ernest Helme Roberts, St. Bartholomew's Hospital; Douglas Robert C. Shepherd, Middlesex Hospital; *Vincent Townrow, Guy's Hospital; and ‖Ethel Margaret Walters, London (Royal Free Hospital) School of Medicine for Women.

* Distinguished in Medicine. † Distinguished in Pathology.
‡ Distinguished in Forensic Medicine and Hygiene.
§ Distinguished in Surgery.
‖ Distinguished in Midwifery and Diseases of Women.

Pass.—Alice Pears Abbott, London (Royal Free Hospital) School of Medicine for Women; Ernest Fryer Ballard, St. Thomas's Hospital; Robert Sidney Barker, Westminster Hospital; Charles Anthony Barker, Guy's Hospital; Frank Cyril Harvie Bennett, St. Mary's Hospital; Phiroshaw C. Bharucha, University College Hospital; Lilias Margaret Blackett, London (Royal Free Hospital) School of Medicine for Women; Sydney Herbert Booth, University of Leeds; John Webster Bride, Victoria University of Manchester; Kate Brown, London (Royal Free Hospital) School of Medicine for Women; Ralph Brown, University College and Westminster Hospitals; Eda Stanley Bryan Brown, London (Royal Free Hospital) School of Medicine for Women; Thomas William Higgins Burne, St. Bartholomew's Hospital; Francis William Chandler, University of Sheffield; Cecil Clarke, University College, Bristol; Cecil Colmer, London Hospital; Ernest Neville Cook, University College Hospital; Ethel Constance Cousins, London (Royal Free Hospital) School of Medicine for Women; Herbert Rees Davies, London Hospital; Rose Lilian Humphrey Davy, London (Royal Free Hospital) School of Medicine for Women; Vaman Ganesh Desai, King's College Hospital; Ethel Adelaide Douglas, London (Royal Free Hospital) School of Medicine for Women; Dean Dunbar, University of Leeds; Douglas Gordon Evans, London Hospital; Robert Cecil T. Evans, B.Sc., and Norman Kessen Foster, University College Hospital; Gertrude Gazdar, London (Royal Free Hospital) School of Medicine for Women; Henry Leatham Grabham; St. Thomas's Hospital; Thomas John Hallinan, Charing Cross Hospital; John Maximilian Hammond, St. Bartholomew's Hospital and University College, Bristol; George Blenkhorn Harland, Guy's Hospital and University of Durham; Henry John Henderson, Guy's Hospital; Susie Eleanor Hill, London (Royal Free Hospital) School of Medicine for Women; Kenneth Hill Hole, Guy's Hospital; William Andrew Morton Jack, St. Thomas's Hospital; William Johnson, Guy's Hospital; Alexander John Kendrew, St. Bartholomew's Hospital; Hugh Braund Kent, Guy's Hospital; Elsie Marian Layman, London (Royal Free Hospital) School of Medicine for Women; John Lewis, University College, Cardiff, and University College Hospital; William Ernest Lord, Victoria University of Manchester; Oswald William McSheehy, St. Thomas's Hospital; Mary Elizabeth Parsons, London (Royal Free Hospital) School of Medicine for Women; Douglas Reynolds, Guy's Hospital; Mabel Russell and Alice Emilie Sanderson, B Sc., London (Royal Free Hospital) School of Medicine for Women; Harry Archibald Sanford, Guy's Hospital; Rachel Hicks Shelley, London (Royal Free Hospital) School of Medicine for Women; Frank Standish, London Hospital; Vernon Harold Starr, King's College Hospital; Kenneth Henry Stokes and John Jerome Suckling, University College Hospital; John Thompson, B.Sc., Victoria University of Manchester; Geoffrey Viner, St. Bartholomew's Hospital; Cuthbert Ferguson Walker, Queen's College, Belfast, and St. Mary's Hospital; Anna Belinda Walsh and Dora Muriel Watney, London (Royal Free Hospital) School of Medicine for Women; Charles McMoran Wilson, St. Mary's Hospital; Horace Richard Wilson, University of Liverpool; Sophia Margaret V. Witts, London (Royal Free Hospital) School of Medicine for Women; Arthur Lowndes Yates, St. Bartholomew's Hospital; and Courtenay Yorke, University of Liverpool.

The following is the supplementary pass list of candidates who have passed in one of the two groups of subjects:—

Group I.—John Nathaniel Beadles, Westminster Hospital; Harry Cecil R. Darling, University College Hospital; Arthur Davies, Westminster Hospital; Irene Cecil Davy Eaton, London (Royal Free Hospital) School of Medicine for Women; Raymond Charles Viner Edsall and William Poole Henley Munden, Guy's Hospital; John Sherwood New, University College Hospital; Hilda Margaret Pollard, London (Royal Free Hospital) School of Medicine for Women; Marion Stocks, Victoria University of Manchester; Robert Archibald Slater Sunderland, St. Bartholomew's Hospital; Robert William Walter Vaughan, University College Hospital; and Lilian Enid Watney, London (Royal Free Hospital) School of Medicine for Women.

Group II.—Leonard Tilley Baker, Guy's Hospital; Henry Lewis Barker, St. Thomas's Hospital; Wilfred Blaydes, St. Bartholomew's Hospital; Charles Herbert Broomhead, Victoria University of Manchester; Angel Camacho, Charing Cross Hospital; Claude Howard S. Fransau, St. George's Hospital; William Lionel Evelyn Fretz, University College Hospital; Eric Leigh Fyffe, St. Thomas's Hospital; Edward Ratcliffe Holborow, University College, Bristol; Matilda Hunt and Mary Sophia Jevons, London (Royal Free Hospital) School of Medicine for Women; Robert Henry Hatten Jolly, Charing Cross Hospital; James Douglas Judson, Victoria University of Manchester; Herbert Cubitt Lucey, Guy's Hospital; Walter Henry Palmer, London Hospital; Eustace M. Parson-Smith, St. Thomas's Hospital; Kenneth Robinson, Victoria University of Manchester; Florence Stacey, London (Royal Free Hospital) School of Medicine for Women; Sydney Arthur Tucker, St. Bartholomew's Hospital; Sybil Albertson Welsh, London (Royal Free Hospital) School of Medicine for Women; and Edward Denis Whittle, University College Hospital.

The names of students who have now completed the M.B., B.S. examination do not appear in this list.

At examinations held in November for internal students the following candidate satisfied the examiners:—

D.Sc. EXAMINATION.

Physiology.—Hubert William Bywaters, University of London (Physiological Laboratory).

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

UNIVERSITY OF BIRMINGHAM.—The following gentlemen have passed the Final M.B., Ch.B. Examination:—

John Adams, George Henry Chavasse Mold, David Priestley Smith, and Henry Philip Thomasson.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held on Dec. 3rd at Caxton House, Westminster, Dr. F. H. Champneys being in the chair. The sitting lasted the whole day, the amount of disciplinary work before the Board being very large. The Board considered the following charges, amongst others, against the midwives whose names are given below and ordered will probably occur very rapidly, while even in the case of spore-bearing organisms, it is quite possible that the spores may have their growth, at the very least, inhibited by the action of the antiseptic, so that the tissues may be able to dispose of them before they begin to grow. In the same way instruments laid down on the towels remain in contact with an antiseptic and are not so likely to become contaminated as if laid on dry cloths. For the same reason I prefer, instead of using dry sterilised linen overalls, to use a mackintosh apron, and to have fastened in front of it a piece of towelling which has been boiled and wrung out of 1 in 2000 sublimate solution. The insignificant amount of antiseptic which might get into the wound from these sources during the course of an operation could not possibly have the slightest effect; it would at once mingle with the blood and be precipitated and thereby rendered inert.

As regards the instruments, after being boiled they are very often placed in salt solution and left there during the course of the operation; in other cases they are kept in alcohol. As regards salt solution, the same thing applies, as I have already pointed out, with regard to dry towels. In the course of time, and not a very long time either, the surface of the salt solution becomes covered *with floating dust, and an instrument taken out of it will* carry with it a considerable amount of dust, which dust retains its vitality. At the same time as the operator picks out instruments he gets dust on his fingers, and while—as I have repeatedly pointed out—this dust is in the great majority of cases innocuous, it may not be so, and it introduces a possible loophole for infection. Hence, just as I have the towels moistened with an antiseptic solution, so I prefer to keep the instruments in an antiseptic solution till they are required for use, that which I use being 1 in 20 or 1 in 40 carbolic solution, which does not injure the metal. In that case the dust falling into the lotion becomes speedily acted upon and all dangerous organisms are rendered inert. I much prefer the carbolic lotion to alcohol, which is not an active antiseptic, and it is just as easy to rinse the antiseptic off the instruments after their removal from the lotion as it is to rinse the alcohol from them.

In a third point I would differ from the extremists in that instead of having only salt solution at hand during an operation, I have an antiseptic solution as well, such as 1 in 2000 sublimate solution, so that the fingers and instruments can be rinsed in it from time to time, and thus any accidental contamination got rid of. It always strikes me as if a surgeon voluntarily deprived himself of a very valuable aid to asepsis when he deliberately avoids having antiseptic solutions at hand during the course of an operation. I do not want the antiseptic solutions for the purpose of deluging the wound with them, but I do want them at hand to rinse my fingers in from time to time, to rinse away the blood from the instruments, and so forth, and for this purpose I always keep at my side a basin containing 1 in 2000 sublimate solution. As I have already said, the minute amount of antiseptic which will gain entrance to the wound as the result of these precautions is of no practical importance whatever, nor has it any injurious effect. In the case of operations on the peritoneum, joints, &c., I employ only saline solutions as soon as the peritoneum is opened, and I have it frequently changed so as to avoid the accumulation of dust on it, and when I wish to cleanse my hands I wash them first in the sublimate and then in the saline solution. I have repeatedly seen in watching operations under so-called aseptic conditions accidental infection of the hands and instruments of the surgeon occur without there being any possibility of removing that contamination owing to the absence of antiseptic solutions. I would point this out strongly as a loophole in the work of the extremists which is an unnecessary one and may lead to trouble.

Another point which has been the source of very considerable trouble to those who avoid the use of antiseptics has been the question of disinfecting ligatures, sutures, &c. As silk and material of that kind are easily enough disinfected by boiling the troubles which have arisen in connexion with deep sutures must, in my opinion, be explained by infection of the material during the course of the operation. This, as I have tried to point out, may quite readily occur where the use of antiseptic solutions is barred. Apparently the greatest difficulty has arisen in connexion with catgut, and to some the difficulty has seemed so great that they have practically abandoned the use of this material. This I think is a great pity. Personally I do not have any trouble with catgut, and I always use Lister's sulpho-chromic gut. As it comes from the instrument maker it is, of course, covered with bacteria. I do not think, however, that bacteria are present, at any rate in any numbers, in the substance of the catgut, because in the process of preparation the bacteria there must have been pretty thoroughly killed, but there is no doubt that on the surface there are any number of organisms. To those who believe only in boiling, or who are afraid of any antiseptic getting into the wound, the disinfection of the catgut presents the greatest difficulty, because boiling in water spoils catgut, however it is prepared. Hence, methods of sterilisation by boiling the catgut in various solutions have been introduced. It must be remembered, however, that Lister had in view other points besides the aseptic character of the material in his methods of preparing catgut, such as the strength of the knot, the length of time required for absorption and so forth. Of late, these points in the preparation of catgut seem to have been lost sight of, and the main question which has been considered has been how to sterilise it. As a matter of fact, I have never found any difficulty in sterilising catgut, nor have I seen any disadvantage from its use. I always keep the *chromicised* gut as obtained from the manufacturer in 1 in 20 carbolic solution for at least a week before using it, indeed, in order to make certain of its disinfection I place it in the first instance for a few hours in undiluted carbolic acid and then for at least a week in 1 in 20 carbolic solution. Before use I place it in weak sublimate solution so as to soak out the carbolic acid and I have never seen any reason to attribute any irritation of the wound to the minute amount of antiseptic which may be carried in with the catgut. As a matter of fact, my belief is that with catgut, as with silk, the real trouble is due to reinfection of the material during the operation and I think this is only another example of how the extremists handicap themselves by their fear of antiseptics.

Before going into the third question, there is one other point to which I wish to make reference—namely, the question of the drainage of wounds. Here, again, I think a retrograde step has been taken by many surgeons. There is no question that if one wishes to carry off fluid, especially if that fluid is thick as in the case of pus, an open tube is much better than capillary attraction. The drainage of wounds by capillary means was worked at a good deal in the early Listerian days, and with the view of avoiding changing of dressings for the purpose of removing tubes absorbable drainage-tubes were employed and also bundles of catgut and so on. The results were not particularly satisfactory and these methods did not take root. At the present time, judging from what is written and what one sees, the use of tubes has been given up to a great extent in favour of drainage by strips of gauze, for what reason I cannot imagine. I think it is a matter of practically no importance in the case of aseptic wounds, for the serum will escape quite readily by capillary drainage, the chief trouble being that if much blood is poured out, the gauze drain is apt to be imperfect as compared with the tube. But where I think the use of capillary drainage is a disadvantage as compared with tubes, is in the treatment of abscesses. Apparently the popular method of dealing with abscesses at the present time is either to pack them with gauze, or at any rate to insert strips of gauze to act as drains, and certainly in the case of sinuses one constantly sees strips of gauze used instead of drainage tubes. Now there are two objections to this; in the first place, gauze will not drain pus properly, and the result is that accumulation is apt to take place behind the gauze plug, and it is quite a common thing to see on pulling out a plug of gauze, that some pus runs out which has really been prevented from escaping by the gauze which had acted as a plug instead of as a drain. The result is that one very often fails to obtain the beautiful result noted by Lister—namely, that if an acute abscess is opened and properly drained and if fresh bacteria are prevented from entering from outside there is no further pus formation. At the present time continued suppuration from an abscess seems to be looked on as a normal state of matters till the abscess cavity closes. In sinuses I think gauze drains are especially bad, because not only do they cork the wound and prevent the escape of the discharge, but, becoming soaked midwives throughout the country, the difficulties of the rural districts being fully realised.

UNIVERSITY COLLEGE HOSPITAL, LONDON.—Sir Victor Horsley will read a paper on "The Cerebellum," on Wednesday, Dec. 16th, before the Medical Society of the hospital in the school, Grafton-street, W.C., Dr. J. S. Risien Russell in the chair. The proceedings will commence at 8.30 P.M.

DONATIONS AND BEQUESTS.—The governors of St. Thomas's Hospital have received from the executors the sum of £3493 8*s.* 6*d.*, the legacy bequeathed by the late Mr. Isaac Lyell Coley. A similar sum from the same source has been received by the treasurer of the City of London Lying-in Hospital.—The late Mr. Henry Barnato has left by will £250,000 sterling for the purpose of founding a hospital or other charitable institution in memory of his late brother, Mr. Barnett Barnato, and of his late nephew, Mr. Woolf Joel.—Under the will of the late Sir George Livesey £10,000 (subject to the life interest of Lady Livesey) will be paid to the King Edward VII. Hospital Fund.—The Ipswich and East Suffolk Hospital will benefit by the sum of £1000 under the will of the late Mr. James Farrow.—By the will of Mrs. Elizabeth Lottle Irving £1000 have been bequeathed to the Manchester Royal Infirmary Dispensary and Lunatic Hospital to endow a bed in her name; £300 each to the Christie Cancer Pavilion and Home, Manchester, the St. Mary's Hospital, Manchester, and Henshaw's Blind Asylum, Manchester, and £200 to the Northern Counties Hospital for Incurables.

CHURCH CONTRIBUTIONS AND THE CLOSING OF THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE, AGAINST ALL RELIGIOUS SERVICES.—As is usual on "Lord Mayor's Sunday," the collections at the morning and evening services at the Cathedral at Newcastle-upon-Tyne were devoted to the medical charities of the district. The amount contributed was only £93, as against £126 last year. More than one explanation has been put forward to account for this very marked decline in the amount given to the medical charities. The prevailing distress as the result of unemployment may in part account for it. Others attribute the falling off in the contributions to the passing of the Old Age Pensions Act and argue that now that the public has to be charitable by Act of Parliament it will cease to contribute voluntarily. However that may be, there can be but little doubt that in the present instance the unfortunate action of the governors of the Royal Victoria Infirmary in closing the infirmary against all religious services at the instance of the Nonconformist bodies of the district must be held largely responsible and this view was held by one of the best known clergymen in the city who appealed to his congregation to give as liberally as they had done in previous years and not to allow any action of the governors to interfere with their contributions to the relief of the sick whose needs were as great now as ever they were. The facts leading up to the closing of the infirmary against religious services may with advantage be outlined here. In 1754 a chapel was consecrated in the old infirmary. When the new infirmary buildings were being erected on the Town Moor a chapel was built in continuation of the chapel in the old infirmary and the cost of building was defrayed out of the money subscribed for the new buildings. The new chapel was consecrated by the bishop on Sept. 19th, 1906. Provision was at the same time made for the Nonconformist bodies to hold services in the infirmary and the students' lecture theatre was made available for this purpose. Services were regularly held in the theatre for a period of nearly 18 months—October, 1906, to February, 1908. The secretary of the Free Church Council cordially acknowledged in several letters to the house governor the efforts of the house committee to secure the comfort and to meet the wishes of the Free Church Council and the arrangements made were adopted as satisfactory by the executive committee of the Council in a letter dated Oct. 18th, 1906. The Nonconformist bodies, however, subsequently demanded equal facilities with the Church of England chaplain in the use of St. Luke's chapel. The house committee addressed a series of questions to Chancellor Tristram, Commissary General, and also obtained an opinion from their honorary solicitors, Messrs. Clayton and Gibson, with a view to ascertain whether St. Luke's chapel could be legally made available for the holding of services not in accordance with the ritual of the Church of England. Chancellor Tristram replied that in his opinion neither the bishop nor any other authority had power to grant a licence whereby the chapel might be available for services conducted by a Nonconformist minister and not according to the ritual of the Church of England. Messrs. Clayton and Gibson replied in the same sense but thought it possible that a special Act of Parliament might be obtained for the purpose, though they did not advise that course partly because it was not certain that such an Act would pass and partly on the ground of expense. At the annual court of governors held on Feb. 29th of this year the house committee reported that acting on these opinions they were unable to accede to the request that St. Luke's chapel should be made available for the holding of Nonconformist services. After an amendment to the effect that a chapel should be erected for the Nonconformists at the expense of the Nonconformists, and that the cost of St. Luke's chapel should be defrayed by an appeal to members of the Church of England, had been defeated by 305 votes to 157, a motion was put that St. Luke's chapel should be closed forthwith and this was carried by 299 votes to 147. A subsequent motion that the students' lecture theatre should be also closed against religious services was agreed to unanimously. The position to-day unfortunately remains unchanged.

MEDICAL INSPECTION IN WORCESTERSHIRE.—At the last quarterly meeting of the Worcestershire education committee Mr. Willis Bund, the chairman, said that it was obvious from the circular sent out that the Board of Education contemplated further additions to the calls on the ratepayers. He suggested that as the work, admirable in itself, was largely national as opposed to local, the council should be advised not to undertake further than it had already done any arrangements for the health and physical condition of the school children. He pointed out that the council had to decide whether it would acquiesce in a Government department raising the rates by adding year by year to the county expenditure, requiring new work to be done and enforcing their desires by threats to withhold the grant already voted by Parliament for work already done by the council. He urged that it should be remembered that the medical inspection scheme now in force, which involved the county in a rate of almost ½*d.* in the pound, was adopted on the assurance of the President of the Board of Education that a Government grant would be made towards the cost, but that grant had not yet been made. At the same meeting the sanitary subcommittee reported the results of the medical inspection so far attained. Up to Oct. 30th 4166 children had been examined, but classified results were only available regarding the 2378 children who had been examined before Sept. 30th; of these it had been found necessary to notify the parents in 1660 cases. Heads were unclean in 524 cases. Defective teeth were present in 254 cases. There were 197 cases of enlarged tonsils, 120 of defective eyesight, 115 cases of anæmia, 70 of consumption, and one of pneumonia. Altogether it had been found necessary to exclude 270 children from the schools, of whom 70 were consumptive.

LONDON SCHOOL OF MEDICINE FOR WOMEN.—The seventh annual dinner of the Royal Free Hospital and the London School of Medicine for Women was held at the Hotel Cecil on Wednesday, Dec. 9th, Miss Aldrich-Blake, M.D., M.S., being in the chair. The company numbered about 120, among whom were Mrs. E. Garrett Anderson, M.D., who this year is the holder of the ancient office of Mayor of Aldeburgh, Mr. and Mrs. James Berry, Mrs. Stanley Boyd, Dr. Walter Carr, Sir W. Watson Cheyne, Dr. H. P. Cholmeley, Mr. Clinton Dent, Mr. and Mrs. Willmott Evans, Mr. A. Pearce Gould, Dr. W. S. A. Griffith, Mrs. Harris, Mr. T. P. Legg, Mr. Clement Lucas, Dr. and Mrs. Harrington Sainsbury, and Sir Felix Semon. The toast list was commendably short, for besides the loyal toasts there were only two—viz., "The School and the Hospital" and "The Guests." The former was proposed in an admirable speech by Miss Aldrich-Blake and responded to by Dr. Sainsbury and the latter was proposed by Mrs. Garrett Anderson and replied to by Dr. W. P. Herringham. A delightful musical programme had been provided, drawn up by Dr. A. G. Phear, the two vocalists being Mr. Louis Godfrey and Miss Hare, who sang amongst other things the old folk-dialogue "The Keys of only say that my own results, and those of surgeons who use antiseptics judiciously, are in every way as good as those obtained with the more elaborate aseptic precautions; in fact, seeing that we are not troubled with sepsis or stitch abscess at all I venture to assert that they are better, because they are more constant and dependable.

FURTHER OBSERVATIONS ON THE TREATMENT OF GOUT BY THYMINIC ACID.

BY ROBERT FENNER, L.R.C.P. EDIN., M.R.C.S. ENG.

IN a paper communicated to THE LANCET[1] I drew attention to the fact that the synthetic manufacture of thyminic acid was an accomplished fact and I gave a table of cases in which it had been exhibited with marked success. If I should appear to attach undue importance to the value of this drug in the treatment of the gouty symptoms it is because I have proved it efficacious in a large number of cases which have yielded to no other treatment. The exhibition of thyminic acid for the elimination of uric acid has its support on such a scientific basis that it is lifted above the stigma of empiricism.

The nitrogenous foods oxidised in the process of digestion may be divided into proteins, paranucleins, and nucleins; of these it is only the nucleins that produce uric acid by splitting up and forming nucleic acid and the purin bases. The purin bases are xanthin, hypoxanthin, guanin, adenin, &c., and it is only in the presence, and by the oxidation, of these that uric acid is produced normally. At the same time, and as a result of the same process, thyminic acid also is formed. Kossel and Minkowski have shown that uric acid will combine and form a compound with thyminic acid. By no process known to chemists can the uric acid be detected when once this compound is formed; it loses its identity and can no longer be precipitated. It is as a constituent of this compound that uric acid circulates in normal blood. We know that it must be present there, yet it cannot be detected; it is its precipitability and not simply its presence in the blood which occurs in gout. The amount of uric acid contained in gouty blood may not exceed the normal, but it tends to be precipitated and we may fairly conclude that this tendency is owing to the fact that its combination with thyminic acid has not taken place or has become unstable. If we could discover why this combination of uric acid and thyminic acid has not occurred, an important advance in the knowledge of the pathogenesis of gout would result. Schmoll says: "There are two possibilities (1) uric acid is formed 'normally,' i.e., by oxidation of the purin bases, but is for some reason not combined with thyminic acid; (2) uric acid is formed synthetically and not by oxidation." Following up the researches of Minkowski and Wiener, he contends that synthetic production of uric acid actually occurs in gout. By treating a series of gouty cases with thyminic acid Schmoll further proved that the free uric acid in the blood had not lost its power to form a compound with thyminic acid.

Thus we see that in gout the uric acid produced by the oxidation of the purin bases can combine naturally with thyminic acid and in this combination passes out of the system, whilst the uric acid of synthetic production has not the amount of thyminic acid at hand necessary for its combination, and this clearly explains why its presence can be detected in the serum. It is therefore this synthesised uric acid deprived of the chance of combining with thyminic acid which is present, and, by its saturation in the serum, becomes precipitated and deposited in the joints and tissues. Again, if the uric acid derived from the oxidised purins be prevented by any cause from combining with the thyminic acid, which comes from the same source, we also have free uric acid in the system. It is well known that in pneumonia, during the absorption of the exudate in the lungs, uric acid is in evidence. Müller demonstrated that the absorption of the inflammatory products takes place by autolysis. During this process the nuclein is split up into the purin bases but the thyminic acid is decomposed (Schmoll); therefore the uric acid has no thyminic acid with which to combine. Thus again in nephritis, the compound of uric acid and thyminic acid is split up in the kidneys and uric acid becomes precipitable in the urine. In the case of the administration of the thymus gland, which contains a large amount of uncombined purin bases, these, absorbed without the complementary thyminic acid, yield precipitable uric acid.

In the gouty state we see that the molecules of uric acid are built up and automatically pieced together, and this synthetically formed and complex molecule is found in the blood and tissues. If, then, thyminic acid can be introduced into the blood by ingestion or other method in sufficient quantities to retain the free uric acid in circulation, the method of rendering the latter soluble is found. Schmoll has conclusively proved that thyminic acid taken by this method passes into the blood stream unaltered. The nitrogen output gradually increases, reaches its maximum, and decreases as the gouty attack diminishes. The thyminic acid, meeting with the uric acid, has formed the requisite combination, biurate of sodium is no longer precipitated, and the uric acid passes out of the system.

It is not within the scope of this paper to discuss the etiology of gout in detail, but it is salutary to insist upon the fact that in a vast number of cases the gouty condition is engendered and maintained by quite preventable causes. It is quite time that heredity and high living were relegated to the list of merely predisposing causes. A very large number of people suffer with gout whose habits and mode of living are so carefully regulated that they do not deserve to be so afflicted. Hunting men and men who get regular and sufficient exercise, men like navvies and labourers who earn their living by the sweat of the brow, suffer to a greater extent than is usually believed. I have seen a number of patients whose dietary has been reduced to the vanishing-point, to whom wine has been denied, who have been dosed and depleted, whose holidays have been spent in mud and salt baths and water-drinking bouts, whose lives have become almost unbearable, but whom a little observation and common sense would have cured. By all means let us enjoin moderation in all things, but at the same time let us be sure that we have discovered the cause of our patient's troubles. Over and over again I have found the gums of patients who have been treated for gout reeking with the pus of pyorrhœa alveolaris. I have before me a series of 78 cases, in 66 of which I have found this trouble. I have been astonished at the manner in which this has been overlooked by doctors and dentists alike. It is difficult to cure and often necessitates the removal of many of the apparently good teeth. Many dentists seem disinclined to take the trouble and so the auto-infection goes steadily on—recurrent attacks of gout occur, and the patient gets disheartened and flies to quack remedies and nostrums. Such are many of the cases that come to me and complain that the treatment they have been ordered has not benefited them. Since I have come to regard gout as of purely toxic origin and have carefully sought for and often found the cause, my results have been more than gratifying. Let us, therefore, seek for evident causes in the treatment of the gouty state. The mouth, throat, and nasal cavities should be carefully examined for local diseases. Evidences of intestinal fermentation or putrefaction should be carefully noted. In these days of rush and the struggle to live, mental worry and overstrain are responsible for a large number of acute and subacute attacks. Attacks of acute lumbago and sciatica are as common among business men who have little opportunity for exercise as among hunting and golfing men who are probably more free from the depression resulting from bad times and the stress of competition.

At the present time a fierce battle is raging over the pathogenesis of gout. The generally accepted belief that uric acid *per se* is the guilty factor has apparently received its death-blow at the hands of such eminent authorities as Walker Hall, Chalmers Watson, Woods, Murchison, Sir Dyce Duckworth, and Luff. The first-named authority says: "As an etiological entity uric acid must be definitely discarded." Luff says: "For my part I have ceased to regard uric acid as in any sense a poison."[2] Sir W. Roberts says: "There is complete absence of direct experimental proof increase the restriction. The Bill was putting much the same into the same category as the most deadly poisons now known. Ireland had its own code of Pharmacy Acts and the Pharmacy Acts now being amended did not apply to Ireland at all. Consequently, it was not originally intended to apply this Bill to Ireland. In response, however, to a great desire among Irish agriculturists Clause 2 was extended to Ireland. Clause 5, which dealt with the vexed question of the drug stores, did not apply to Ireland. If, however, he found that there was a general desire in Ireland to have Clause 5 applied to Ireland he should only be too happy to take that into consideration.

---

[1] Uric Acid: A Rational Treatment for its Elimination in the Light of Recent Research, THE LANCET, July 1st, 1905, p. 19.

[2] Transactions of the Medical Society of London, vol. xxx., p. 73.

The Bill was read a second time.

White Phosphorus Matches Prohibition Bill.

The House considered the White Phosphorus Matches Prohibition Bill on report.

The Earl of BEAUCHAMP, in moving the omission of Clause 1, said that the object of the Bill was to prevent the spread of necrosis. From the very few cases of this disease in the last few years it appeared to be practically extinct. He feared that the result of prohibiting the manufacture of white phosphorus matches would be the formation of a large trust or combine amongst the manufacturers of matches in the country.

Mr. GLADSTONE replied that it was true that only a few cases of necrosis had occurred during the last three years and the immunity had been secured at the expense of very great trouble and continual watchfulness. He would not say now that the match trade was the main or principal source of this very dreadful and terrible disease. He did not see any fear of a combination of match manufacturers being formed as the result of the Bill.

The amendment was withdrawn.

The Bill subsequently passed through the report stage and was read a third time.

FRIDAY, DEC. 4TH.

The Cost of Medical Inspection of School Children.

Mr. RAMSAY MACDONALD asked the President of the Board of Education whether he had received representations from local authorities drawing his attention to the expense of medical inspection provided for by the Education (Administrative Provisions) Act of last year, and whether any further assistance was to be provided from the Exchequer so as to enable this inspection to be carried on efficiently.—Mr. RUNCIMAN replied (by written answer): I have already stated that there is, in my opinion, the strongest objection to giving special grants for special purposes in connexion with elementary education, but under the financial proposals in connexion with the Bill now before the House local education authorities will receive a large additional grant to assist them in carrying out medical inspection and their other duties in respect of elementary education.

TUESDAY, DEC. 8TH.

A Surgeon-Captain and the Territorial Force.

Mr. WATT asked the Secretary of State for War whether his attention had been called to the case of Surgeon-Captain James Swanson, late of the 1st Battalion Highland Light Infantry, whose headquarters were in Glasgow; whether he was aware that this officer had a very distinguished career of 15 years in that regiment; that he in two successive years won the challenge shield for Great Britain, and in a third year was second for it; that he was on several occasions complimented by his commanding officers for his excellent work; yet when he expressed willingness to transfer to the new Territorial Army was not recommended in July for transfer to the new force; and would he inquire into this case and find out why the service was refused to this officer.—Mr. HALDANE replied: I have made inquiry into this case. The general officer commanding-in-chief, Scottish command, reports that after full consideration of the case he was satisfied that this officer should not be transferred to the Territorial Force.

The Medical Inspection of School Children.

Mr. [illegible] asked the President of the Board of Education whether he would, either by regulation [illegible] or, if not, by amending legislation, provide the means to enable local education authorities to proceed against parents who withhold their children from medical inspection and thereby reduce the effectiveness of Section 13 (1) (b) of the Education (Administrative Provisions) Act, 1907.—Mr. RUNCIMAN furnished the following written reply: The Board has reason to believe that the number of children withheld by their parents from medical inspection is inconsiderable, and that as the benefits of such inspection become better known the number will decrease. At present the Board do not consider that any special action on their part is required or desirable.

The Sale of Food and Drugs Act in Cavan.

Mr. VINCENT KENNEDY asked the Chief Secretary to the Lord Lieutenant of Ireland to state for how many years past there was a record of samples taken under the provisions of the Food and Drugs Acts in Cavan; [illegible] how many convictions were [illegible] were records kept, what steps were taken to secure that the results of analyses were [illegible] accurate, and would he say of the 100 samples submitted in Cavan in 1907, how many were analysed by the public analyst and how many [illegible].—Mr. BIRRELL (by written answer) replied: The Local Government Board inform me that they are satisfied as to the qualifications of the analyst for county Cavan. They have no official information as to the other matters referred to in the question.

The [illegible] Hospital at Stornoway.

Mr. WEIR asked the Secretary for Scotland, in view of the fact that there was a population of nearly 30,000 in the Island of Lewis, would he state the extent of the accommodation in [illegible] cases of [illegible] in the [illegible] Hospital at Stornoway.—Mr. SINCLAIR wrote in reply: I am informed that the hospital has room to accommodate ten patients.

WEDNESDAY, DEC. 9TH.

The Report of the Departmental Anthrax Committee.

Mr. [illegible] asked the Secretary of State for the Home Department whether, in connexion with the report of the Anthrax Committee [illegible] of the Bradford Chamber of Commerce which points to the fact that the germs of anthrax were to be [illegible] and in [illegible], he could state that any of the rules [illegible] now in force [illegible] the sorting and handling of foreign wools and hair [illegible].—Mr. GLADSTONE furnished the following written answer: The investigations of the Anthrax Board are not yet completed, and it will be seen, on referring to page 9 of the report, that dust is still regarded as a source of danger. It would therefore be premature to propose any alterations in the existing rules at the present time. Regulations may not prove to be practicable.

HOUSING AND TOWN PLANNING BILL.

The Standing Committee of the House of Commons which was charged with the consideration of the Housing and Town Planning Bill dealt with proposed new clauses on Thursday, Dec. 3rd.

Sir JOHN DICKSON POYNDER moved the following new clause:—"Every county medical officer of health shall make periodical reports to the public health and housing committee of the council, and if it appears to the county council from any report of such committee or medical officer that the Public Health Act, 1875, the Local Government Act, 1894, the Housing Acts, or any Acts amending or extending the same, have not been properly put in force within any county district to which the report relates, or that any other matter affecting the public health of the district requires to be remedied, the county council may institute any proceedings and do any act which the council might have instituted or done for that purpose, and shall be entitled to recover from the district council in default all such expenses in and about the said proceedings or act as the county council incur, and are not recovered from any other person, and have not been incurred in any unsuccessful proceedings." He said that he only moved this new clause for the purpose of getting to know the views and intentions of the President of the Local Government Board on the subject. Would the right honourable gentleman include a clause similar to this one in the regulations to be issued under the Bill? Unless something of the kind was provided there would be friction between the county medical officer of health and the district medical officer. Some such provision as he proposed would be most useful.

Mr. BURNS said that he understood the honourable baronet moved the new clause less with the intention of getting it in the Bill than as a direction to the Local Government Board to act, through their regulations, generally on the lines laid down in the clause. If it was intended to embody the clause in the Bill he could certainly not accept it in its present form. However, as it was put forward to ascertain how the Local Government Board intended to act in this particular matter he could tell the honourable baronet that it did not include a number of matters that might be included. There had been one or two instances of [illegible] already when such things were concerned. It might happen that both the county council and the district council would refuse to act, and then it ought to be that the Local Government Board should have power to act in default of the two authorities. The Local Government Board intended in its regulations to give full scope to what the honourable baronet desired. There would be one or two additions to give the superior body more default powers.

Sir JOHN DICKSON POYNDER said that he was satisfied with the answer of the President of the Local Government Board, and he therefore asked leave to withdraw his proposed new clause.

The clause was then withdrawn.

After further discussion the Committee stage of the Bill was completed and it was ordered to be reported to the House.

BOOKS, ETC., RECEIVED.

AMERICAN LARYNGOLOGICAL ASSOCIATION, New York. (Dr. J. E. NEWCOMB, Secretary, 118, West 69th-street, New York City, U.S.A.)

Transactions of the Thirtieth Annual Meeting of the American Laryngological Association held at Montreal, Canada, May 11th, 12th, and 13th, 1908. Price not stated.

BAILLIÈRE, J. B., ET FILS, 19, Rue Hautefeuille, Paris.

Traité des Maladies des Vieillards. Par le Docteur G. Rauzier, Professeur de Pathologie et de Thérapeutique Générales à la Faculté de Médecine de Montpellier. Préface de M. le Professeur Grasset. Price Fr. 12.

BAILLIÈRE, TINDALL, AND COX, 8, Henrietta-street, Covent-garden, London, W.C.

Handbook for Attendants on the Insane. Fifth edition, revised and enlarged. Thirty-third thousand. Published by the Authority of the Medico-Psychological Association. Price 2s. 6d. net.

The Pros and Cons of Vivisection. By Dr. Charles Richet, Professor of Physiology in the Faculty of Medicine, Paris. With a Preface by W. D. Halliburton, M.D., LL.D., F.R.S., Professor of Physiology, King's College, London. Price 2s. 6d. net.

irritable condition so often associated with the gouty state. I have been very gratified to note the marked relief this combination has given to many of my patients. But salicylic acid and its derivatives have no marked or lasting effect for good and are only useful as aids in the treatment of symptoms.

4. The alkaline treatment consists of the administration of the salts of potash, soda, or lithia. It has been pointed out that a large dose of bicarbonate of potassium at bedtime stems "the acid tide," and this may be true as regards the "initial acidity" and merely applies to the stomach. It can have no effect upon the "uric acid tide," to develop later. The treatment of gout by alkalies is carried out nowadays entirely by the action of the waters of the various natural springs. All forms of mineral waters are beneficial but mainly owing to the good effect of their largest constituent —viz., water.

Sir W. Roberts claims to have shown conclusively that alkalies are useless and have no influence whatever on the sodium biurate. "The sodium salts are particularly harmful, and yet the gouty from all parts of the world are sent to those very continental springs in which these salts predominate. *The efficacy in the treatment is in the water* [the italics are mine], the method of imbibing it, the regulated and modified diet, the observance of proper hours, exercise, and absence of worry with its corresponding peace of mind."[6] One is not surprised, therefore, to find that so many of one's patients work up an acute attack of gout during the treatment at these spas or immediately on their return. It is poor comfort to be told by the physician that "this is to be looked for," to which is added a real grain of comfort that "this gouty storm is but a flash in the pan and that great and lasting improvement will follow."

Dr. Labbé in "La Diathèse Urique" gives a most interesting description of the action and uses of these various drugs. After describing their chemical properties, he writes: "There are a great number of chemical combinations which have the property of dissolving and retaining in solution considerable quantities of uric acid as compared with their own weight. Of these not one can be said to be 'physiological.' All these substances are absolutely foreign to the organism *and as such cannot be used for a long time or in great quantities with impunity* [the italics are mine]. Further, if their dissolving power has been proved and measured *in vitro* it has not been demonstrated that *in vivo* the complex combinations in which they may be called upon to act do not modify and render inert their therapeutical properties. It is this point of view which has caused certain authors to seek the possible existence of physiological combinations formed by the union of uric acid with certain compounds existent or pre-existent in the organism. The theory of the constant circulation of uric acid in the organism under the form of a combination which is permanent and not precipitable in acid with the substance *thyminic acid* or nucleotin-phosphoric acid has been discussed elsewhere." (Ibid., p. 15.)[7]

For the past five years I have treated a very large number of cases of gout and kindred affections, and have made a careful study of the effects produced by the administration of thyminic acid. I should like to preface my remarks with a word of warning: thyminic acid is not, and never can be, a panacea for each and every variety of the gouty state. My observations, however, lead me to claim for thyminic acid the power of preventing the formation of free uric acid in the serum and its deposition in the tissues and joints. In my former paper I showed that thyminic acid had an enormous advantage over any of the so-called solvents in its retentive power for uric acid, that all tests were valueless in detecting the presence of uric acid when combined with its desideratum of thyminic acid, and that its exhibition has proved of the greatest service in the treatment of cases which had resisted all ordinary drugs. Thyminic acid may be given in the compressed tablet form or in powder. The first form is the most convenient, the taste is not unpleasant, and to secure rapid absorption the tablets may be masticated. Careful observation has proved that my former dose of 12 grains per diem may with advantage be increased to 24 grains—that is, a dose of eight grains after the three principal meals. Given in this way there are absolutely no unpleasant effects, and in my own practice and in that of many hundreds practising in the United Kingdom and abroad practically none have been produced after a long use of this drug. Those that have been recorded appear to have been due to some idiosyncrasy of the patient. It has certainly no deleterious action on the heart, the digestion, or the secretive organs. Not a single patient has complained of any depression; on the contrary, its action is distinctly tonic, due probably to the phosphoric acid it contains and to the rapid amelioration of the gouty symptoms. At the beginning of the treatment patients have occasionally complained of some fugitive pains in the lumbar region and in the various joints, but these quickly subside under the continued use of the drug. In acute cases I find that a larger dose should be given and I often combine with it, in a cachet, colchicum or aspirin. From eight to ten grains may advantageously be given every four hours. In chronic cases of the arthritic variety, where more or less permanent injury has occurred in the joints, a smaller dose of four grains should be taken over a prolonged period, and it is in these cases, contrary to one's expectation and in those troublesome forms of irregular gout, that thyminic acid gives very gratifying results. As regards general treatment in acute cases I forbid from the very outset all purin-containing foods. Large quantities of milk and Vichy water or skimmed milk and vegetable soups with well-cooked toast should be given, and if rapid loss of strength occurs chicken and veal broth and light milk puddings. The swollen joint should be placed in an electric-ray light bath and the temperature gradually raised until the thermometer registers from 200° to 240° F. At this heat gentle local diaphoresis occurs. The part may then be bathed in a hot alkaline solution or immersed in an alkaline bath, carefully dried, and protected from the weight of the bed-clothes. If the patient is sitting up the part should be raised and a light medicated wool dressing applied and lightly bandaged. I seldom apply outward applications during this stage; I find they are practically useless. This proceeding may be repeated at intervals of six hours and the symptoms gradually subside. When the swelling has subsided gentle massage of the muscles and tendons may be commenced, but all movement of the joints should be forbidden. This word of caution is necessary, as the highly-trained masseur of to-day is always anxious to perform gymnastics with joints when given the opportunity. The dose of thyminic acid may be reduced to 24 grains a day as the pain and swelling subside, and continued for some three or four weeks, and then again reduced to 12 grains per diem.

In attacks of acute sciatica and lumbago I find nothing so efficacious locally as the application of the high-frequency current in the form of the effleuve and massage with the vacuum glass electrode. The first vigorous application greatly lessens the pain and frequently allays it, while usually two or three applications are sufficient to bring about a cure. In some cases I find that thyminic acid administered by the mouth is unable to effect a sufficiently rapid cure, but in the chronic forms it is of the greatest service in mitigating pain and loss of muscular power which are the chief symptoms. It has also a very marked effect in entirely preventing or in greatly lengthening the period between the attacks in those who suffer from recurrent sciatica or lumbago.

A very valuable help in the treatment of all gouty cases is the ray light bath which can now easily be procured at a reasonable price and may be lighted from the ordinary electric plug from the main. A temperature of from 130° to 140° F. is generally sufficient and adequate diaphoresis obtained in from 15 to 18 minutes. If followed by a warm or tepid bath and brisk towelling it is most beneficial and invigorating. This may be taken two or three times a week and in the local treatment of joints nothing is more soothing and beneficial in the relief it gives to pain and swelling.

I have had prepared a sterilised solution of thyminic acid equivalent to two grains of the powder for intramuscular injection and carefully conducted experiments on rabbits and guinea-pigs proved that the injection was well borne and harmless. I was then fortunately able to test its efficacy on myself. The pain that I had suffered for three weeks, probably owing to some deposition within the joint, with resulting neuritis of the musculo-spiral nerve, was very greatly lessened by one intramuscular injection into my shoulder. Another injection on the following day completely removed the symptoms and I have been free since. A professional brother also allowed

[7] Translated.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £150 per annum, with rooms, attendance, board, and washing.

MANCHESTER, MONSALL FEVER HOSPITAL.—Senior Assistant Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and washing.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer. Salary £150 per annum, with board and residence.

MERTHYR TYDFIL EDUCATION COMMITTEE.—Medical Inspector of School Children. Salary £200, rising to £250 per annum.

MIDDLESEX HOSPITAL, W.—Medical Registrar, Surgical Registrar, and Obstetrical Registrar. Also Second Assistant to the Director of the Bacteriological and Clinical Laboratories. Salary £100 per annum.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Assistant Resident Medical Officer. Salary £50 per annum, with board and residence.

NEWCASTLE-UPON-TYNE, CITY LUNATIC ASYLUM, Gosforth.—Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, and laundry.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £150 per annum.

NORTHAMPTON GENERAL HOSPITAL.—Senior Resident Medical Officer, unmarried. Salary £120 per annum, with apartments, board, washing, and attendance.

NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon (female) for six months. Salary at rate of £50 per annum, with board, &c.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £50 per annum, with board, lodging, and washing.

OXFORD EYE HOSPITAL, Walton-street.—Resident House Surgeon. Salary £100 per annum, with board and lodging.

...TH DISTRICT ASYLUM, Merthyr.—Assistant Medical Officer. Salary £150 per annum, with rooms, board, and washing.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

ROYAL EAR HOSPITAL, Soho.—House Surgeon for six months. Salary at rate of £50 per annum.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Junior Resident Medical Officer. Salary at rate of £50 per annum, with board and washing.

ST. GEORGE'S HOSPITAL, Hyde Park-corner, S.W.—Resident Anæsthetist. Salary at rate of £100 per annum, with board and residence.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—Clinical Assistants.

ST. PANCRAS INFIRMARY (NORTH), Dartmouth Park-hill, N.—Junior Assistant Medical Superintendent. Salary £75 per annum, with apartments, rations, and washing.

SOUTHPORT, COUNTY BOROUGH OF, EDUCATION DEPARTMENT.—School Medical Officer. Salary £250 per annum.

SUNDERLAND, MONKWEARMOUTH AND SOUTHWICK HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

WANDSWORTH UNION INFIRMARY, St. John's Hill, near Clapham Junction.—Junior Assistant Medical Officer, unmarried, for six months. Salary at rate of £120 per annum, with board, lodging, and washing.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon. Salary at rate of £75 per annum, with board, residence, &c.

WEST LONDON HOSPITAL AND POST-GRADUATE COLLEGE, Hammersmith-road, W.—Clinical Assistants. Also Casualty Officers.

WESTMINSTER GENERAL DISPENSARY.—Honorary Surgeon.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Assistant Surgeon. Also Medical Registrar. Salary £50 per annum.

YORKSHIRE, PENTH UNION AND RURAL DISTRICT COUNCIL.—Medical Officer (Muker District) and Medical Officer of Health (Whole District). Salaries £25 and £50 respectively.

Births, Marriages, and Deaths.

BIRTHS.

BARWELL.—On Dec. 4th, at Wimpole-street, the wife of Harold Barwell, M.B., F.R.C.S., of a son.

HILL.—On Dec. 4th, at St. Domingo, Hoylake, the wife of Charles A. Hill, M.A., M.B., B.C. Cantab., D.P.H., of a son (Charles Gore).

PASMORE.—On Dec. 2nd, at Warlingham, the wife of Dr. E. Stephen Pasmore, M.R.C.P., medical superintendent of Croydon Mental Hospital, of a son.

THOMSON.—On Nov. 30th, at Bath, the wife of F. G. Thomson, B.A. Cantab., M.D. Lond., M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

FALCONER—CLARKE.—On Dec. 5th, at McFadyen Memorial Church, Chorlton-cum-Hardy, by the Rev. David Walters, James Law Falconer, M.B., F.R.C.S., of 22, Chorley New-road, Bolton, to Lena, daughter of Thos. Clarke of Whalley Range, Manchester.

SHORE—HALL.—On Dec. 8th, at St. Mary Abbots, Kensington, Lewis Shore, M.D., Fellow of St. John's College, Cambridge, to Agatha Catherine, daughter of R. Gresley Hall, D.L.

DEATHS.

BEEVOR.—On Dec. 5th, at Harley-street, W., Charles Edward Beevor, M.D., F.R.C.P., aged 54 years.

DAVIES.—On Dec. 2nd, at Holmfield, Ewell, Surrey, Francis Pritchard Davies, M.D., aged 64 years.

HENRY.—On Dec. 2nd, at Strathmore, Leckhampton, Cheltenham, Lieutenant-Colonel J. J. Henry, R.A.M.C., aged 79 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

NEGLECTING CHILDREN.

ONE of the most depressing aspects of certain portions of what we call civilised life is the callousness and cruelty so often shown to helpless infants. Frequently, too, it is accompanied by gross immorality, of which, indeed, it is often an incidental product. A particularly bad case was brought under observation as the result of an inquest on an illegitimate child that was held in Harpurhey, Manchester. The father of the family earned £1 17s. a week and two of his seven children brought up the income to £2 15s. The father was charged with neglecting two of his children. One daughter, Edith, was charged for neglecting her illegitimate child. Another daughter, Laura, had so neglected her child, also illegitimate, that he died. Instead of weighing about 17 pounds, as he should have done, he only weighed 6 pounds. Though two years old, the child of Edith, who had so far survived, could not even stand. The father's excuse was that his wife died seven years since and things had been "at sixes and sevens." He was bound over but his two daughters were sent to prison for six months each. Is the education that is promised in the future going to be more successful than that which we have had for more than 30 years past in training up children? Will it build up character and good citizenship more thoroughly than during the old order? If not, the omens for the future of the people, or for a large percentage of them, look discouraging.

A WANT IN PUBLIC URINALS.

To the Editor of THE LANCET.

SIR,—Although the phrase "want to wash your hands" is a euphemism for urination, I have for years been struck with the want of opportunity for touching the hands at our public urinals where so much water runs to waste. I would urge on our great firms who manufacture earthenware for sanitary fittings, and upon sanitarians generally, the boon that one or two taps of running water for the purpose of rinsing the hands after micturition would be, especially when one reflects how many individuals, butchers, bakers, bankers, &c., who handle food, money, &c., suffer from local maladies and have no opportunity of hand ablution before handling goods, &c., on their rounds, office, &c. I have been moved to bring forward the above after reading Dr. D. S. Davies and Dr. I. Walker Hall's suggestions for "typhoid carriers" in THE LANCET of Nov. 28th, and trust my suggestion may attract the attention of our great pottery firms and those authorities who order their earthenware.

I am, Sir, yours faithfully,

Dec. 7th, 1908. POUR LES HOMMES.

A NEW EMPLOYMENT FOR LADIES AND GENTLEMEN.

THE following advertisement appeared in the *Morning Post* on Dec. 7th:—

> A QUALIFIED DENTAL SURGEON (West End) offers handsome Commission to any Lady or Gentleman introducing NEW PATIENTS, ledger may be inspected at completion of work, *only good-class patients accepted*, confidence and secrecy expected and given.—Address C., 0191b, "Morning Post" Office, Strand, W.C.

This should attract the attention of others besides the ladies and gentlemen who are invited to act as touts for the advertiser and to earn a presumably secret commission by doing so.

WANTED—A HOME.

To the Editor of THE LANCET.

SIR,—Can any of your readers recommend to me a home that would receive a woman 52 years of age suffering from rheumatoid arthritis deformans. She is quite able to do a useful amount of work, and 8s. a week would be found for her care.

I am, Sir, yours faithfully,

242, Westgate-road, Newcastle-on-Tyne, JAMES D. FARQUHARSON.

Dec. 2nd, 1908.

HEALTH IN THE STRAITS SETTLEMENTS.

IN his annual report Mr. Arthur Young, Colonial Secretary, gives the population of the Straits Settlements as 619,750. The death-rate was 39·07 per 1000 and the birth-rate 25·11 per 1000 of the population. There were ten deaths from small-pox, 223 from cholera, 1535 from beri-beri, and 15 from plague. The stringent quarantine regulations and the vigilance of the medical and municipal authorities have hitherto prevented these scourges from finding a permanent home in the colony. The mean temperature of the air at Singapore was 80·5° F., at Penang 80·3°, and at Malacca 79·9°. The mean rainfall at Singapore was 91·25 inches, in Penang 97·55 inches, in Province Wellesley 75·78 inches, in the Dindings 95·21 inches, and in Malacca 71·35 inches. In spite of the high death-rate the climate in the towns and country cannot be considered unhealthy for Europeans, who, with their higher and more sanitary mode of life, can, if they take ordinary precautions, to a great extent avoid the malarial and other tropical fevers and dysentery which attack the Oriental inhabitants of the peninsula. Practically all the hospitals of the colony are

a , taking much exercise. Present
at thrice daily the attacks became
le ... ... months ago, the longest interval
of health he has had hitherto.

CASE 10.—A boy, aged 13 years. Previous history: Eczema almost from birth. Present attack (July 6th, 1906): Face, hands, and chest covered with purulent eczema; has been unable to attend school. Treatment: 4 grains thyminic acid three times a day; byno-glycerophosphates. Remarks: Is now attending school and only occasionally has an outbreak on the fingers.

CASE 11.—A man, aged 60 years. Previous history: Has had gouty symptoms for many years. Present attack: Gastric catarrh; acute dyspepsia; stomach much distended; gastralgia. Treatment: 8 grains thyminic acid three times a day; high-frequency electricity. Remarks. Symptoms subsided in three weeks. Is now able to digest food; stomach nearly normal.

CASE 12.—A woman, aged 60 years. Previous history: Gradually increasing obesity. Present attack: October, 1906; weight, 12 stones 3 pounds; May, 1907, weight, 11 stones. September, 1908; weight, 10 stones 1 pound. Treatment: 8 grains thyminic acid three times a day. Remarks: Can now take walking exercise with comfort and has not increased in weight; is strong and in good health.

CASE 13.—A man, aged 50 years. Previous history: Has suffered from attacks of acute gout for several years. Treatment: Since taking thyminic acid regularly during the past three years has been quite free.

Queen Anne-street, W.

OTOSCLEROSIS: SOME POINTS IN ITS ETIOLOGY, DIAGNOSIS, AND TREATMENT.

BY ALEXANDER R. TWEEDIE, F.R.C.S. ENG., L.R.C.P. LOND.,

LATE CLINICAL ASSISTANT AT THE HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE, LONDON, ETC.

A VAST amount of work has of recent years been carried out to elucidate the morbid processes on which the disease "otosclerosis" depends. Its pathology has thus been fairly well established, and its history and course are comparatively well known, but its cause is still most obscure. It must further be admitted that its diagnosis, especially in the initial stages, may at times be most difficult, whilst as regards its treatment we do not yet know any method or drug which can be claimed as curative.

It is usual to find the description of otosclerosis in text-books on diseases of the ear included in those chapters dealing with chronic inflammatory or catarrhal processes of the tympanic cavity. This arrangement, however, is at least most misleading, as the disease is neither catarrhal in origin nor the result of an inflammation in the ordinary acceptance of this term, nor does it originate in the middle ear. It is dependent on totally different causes and must be treated by quite different methods. The chief pathological changes may be described as consisting in the formation of small well-defined areas of newly-formed bony tissue which replace the true bone. These occur probably as the sequel of a local trophic disturbance or vascular stasis and consist in the rarefaction of the parts so affected, which subsequently become sclerosed and in places proliferated. Between these pathological changes and the healthy adjacent bone a sharp line of demarcation exists. The commonest site for these alterations is the anterior superior angle of the oval window, and their chief result is ankylosis of the stapedio-vestibular joint.

Bearing in mind the pathological changes, it is obvious we are dealing with a condition which is necessarily most unresponsive to drugs or any method of treatment. It may be improved, however, or perhaps it would be more accurate to say may be arrested, by the exhibition of drugs and by general treatment when circumstances permit an ideal life in healthy surroundings, especially if at the same time care and worry can be reduced to a minimum and the least possible demand made on both the mental and bodily energies.

Etiology.—As already mentioned, the causes which lead to the production of the pathological changes in "otosclerosis" have yet to be determined. The disease, however, seems to be attributable either to circumstances which affect the general nervous system or to alterations of the normal condition of the blood and circulatory mechanism. Thus its commencement can be constantly referred to shock, fright, sudden grief, or prolonged mental anxiety, whilst as instances of the second group of causes, chlorosis, anæmia, severe hæmorrhage, and parturition may be mentioned, and its incidence is traceable at times to the establishment of the menstrual functions in young girls. General febrile conditions also have a causal relation to its onset, influenza being especially noticeable in this respect; and finally it appears to be much commoner in people of the neurotic type.

Most statistics reveal that "otosclerosis" is slightly more common amongst women than men, the reason for which is assigned by some to the relation which parturition appears to have, both as regards its onset and further progress. When we consider, however, how much more likely all the probable causes are to affect the female sex it is not surprising to find as a matter of practical experience that it occurs even more commonly amongst women than the published records indicate. The disease is often found in several members of the same family, though neither of the parents may be afflicted. Still many of these patients, as already stated, are neurotic, and thus heredity may have some influence on its occurrence.

Course.—The disease commences probably in the second or third decade of life, though perhaps patients most frequently seek advice between the ages of 25 and 35 years. Its onset is most insidious and its first symptom is either slight tinnitus or a condition of apparent inattention, observed by others, especially when several are conversing together, as, for instance, at table. The patients may be unaware of this latter abnormality, and thus it occasionally happens that it is chiefly the anxiety of friends which leads them to seek advice. These early symptoms are particularly important because it is at this stage especially that we should urge active treatment. If further progress can now be arrested, although existing lesions are not cured, the condition of the patients will be far less distressing than when they themselves realise their misfortune and both advanced deafness and tinnitus have become a source of continual worry and annoyance to them; to say nothing of the obvious disadvantage and severe handicap to which they are then subjected on all sides.

If untreated in the early stages the deafness and tinnitus are progressive in varying degrees of rapidity as regards the ear first attacked, whilst almost always the other ear also sooner or later becomes similarly involved. Acute exacerbations of the disease also occur often associated with those affections mentioned above as etiological factors. The loss of hearing may ultimately become extreme though the disease very rarely leads to absolute deafness. The tinnitus may persist or as the power of hearing depreciates may become less and less so as to be almost negligible, or it may indeed absolutely disappear.

Diagnosis.—The objective examination is chiefly "negative"—that is to say, the tympanic membrane is found normal or nearly normal, though it sometimes presents a peculiar pinkish hazy appearance, often quite characteristic though difficult to describe accurately. The membrane is moveable together with the handle and short process of the malleus, and there are no signs of inflammatory or catarrhal conditions either past or present. The nasal passages and Eustachian tubes are often found unusually patent, due apparently to collapse and anæmia of the mucous membrane in these situations. The external auditory canal, too, is often so patent that at times a good view may be obtained of the tympanic membrane without the aid of the speculum, whilst its lining membrane is white and shiny and peculiarly deficient in wax.

Though these are the conditions usually found on examination cases do occur in which there is co-existent catarrh of the middle ear and Eustachian tubes associated with rhinitis and naso-pharyngitis. The deafness and tinnitus may be aggravated by these complications, but for the most part persist even when such catarrhal changes subside or respond to treatment. Operative or energetic local treatment, however, in this direction should be adopted with great caution as it may only intensify the deafness and tinnitus. If possible it is better avoided or only tried tentatively in such cases as present some doubt as to the existence of otosclerosis.

The functional tests, as a rule, afford very similar results to those found in any other lesions which involve the conductive apparatus of the middle ear, and may be shortly enumerated as consisting in marked depreciation of the range of perception for whispers; little or no lowering of the upper tone limit; definite raising of the lower tone limit by air conduction; perception *viâ* the bone greater than *viâ* the air; bone conduction greater than that of a normal

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics.—Medical Out-patient (Dr. A. J. Whiting), Surgical (Mr. H. W. Carson), X Rays. 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture Demonstration:—Dr. A. G. Auld: Methods of Diagnosis applicable to Abdominal Organs.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Fungous Diseases (continued): (3) Favus, (4) Leptothrix.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Dr. G. Stewart: Spinal Caries.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Mr. Collum: The Administration of Anæsthetics to Children.

OPERATIONS.

METROPOLITAN HOSPITALS

MONDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.)

TUESDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.)

WEDNESDAY (16th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.)

THURSDAY (17th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.)

FRIDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)

SATURDAY (19th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received.—*Liverpool Daily Post, South Wales Daily News, Manchester Evening News, Birmingham Evening Despatch, Daily Mail, Daily Chronicle, [illegible] Observer, Eastern Morning News, Norfolk Weekly Standard, [illegible] Mail, Grimsby Telegraph, Nature, Pall Mall Gazette, Nottingham Evening Post, Blackpool Gazette, Liverpool Post and Mercury, [illegible] Gazette, Scientific American, &c.*

mastoid region. Such sudden increase of the deafness or tinnitus is probably not due to rapid extension of the disease itself to other parts of the inner ear but to a temporary local congestion of the vascular system of the labyrinth which may be expected to bear more heavily on areas already diseased. Such conditions, however, if untreated may very possibly lead to a further spread of the disease and a permanent increase of the symptoms.

Apart from the drugs necessary to combat any general dyscrasia from which the patient may be suffering tonics, such as strychnine, phosphorus, or arsenic alone or combined with the iodides, should be advised. This treatment in the first instance should be adopted for a period of some six months with short remissions and then short courses of these medicines extending over six weeks should be advised two or three times a year. In this way the further progress of the disease may be controlled to some extent, though, of course, a cure of already existing lesions cannot be expected. Such treatment, however, often makes the patient more comfortable generally, reduces the tinnitus, and apparently improves the hearing. The improvement is usually more apparent than real and is due probably to the relief of the subjective noises, for the results to the functional tests remain much the same.

Tinnitus and occasionally vertigo may require special treatment, for which purposes the bromides, hydrobromic acid, and drugs of like action are still probably the best. They should be used to give temporary ease pending the more permanent relief from the general and therapeutic measures recommended above. Unfortunately severe tinnitus points to an irritative lesion in the cochlea and vertigo to a similar affection of the walls of the semicircular canals, and consequently the exhibition of such sedatives may meet with little response. A course of Weir-Mitchell's rest cure is said to be often of great benefit in cases of otosclerosis with extremely marked subjective symptoms occurring in neurotic subjects.

Whatever drugs or method of treatment are used the patients should be told that only a prolonged course as above suggested can be expected to be of any service. If they are not disposed to carry this out the sporadic "taking a bottle of medicine" means only useless expense to them.

That the treatment outlined above is vague and empirical must be admitted, yet it is justified by the results obtained, and till a better and possibly specific treatment is discovered should certainly be employed.

Artificial aids to hearing are sometimes useful, but little can or need be said of them. Generally speaking, the more cumbersome and unsightly the more valuable they are, but the best plan is to advise the patient to visit a reliable maker of such instruments and to purchase that which affords him most relief if such aids are desired.

In the past patients afflicted with otosclerosis have often been allowed to drift without appropriate treatment and without warning as to the probable course of the disease so that they have become the prey of the quack and his advertisements, and the object of this paper is to urge the importance of early recognition and early and prolonged treatment of this condition. Though a cure cannot be expected, a certain amount of relief may be obtained and, what is much more important, the further progress of the disease may be controlled or actually arrested. An excellent and most exhaustive monograph, "Die Otosklerose," has been written by Dr. Denker of Erlangen, in which those who are sufficiently interested in the subject will find it ably discussed.

In conclusion, I wish to express my gratitude to Mr. C. A. Parker for the great help he has given me in preparing this paper whilst working with him at the Throat Hospital, Golden-square.

Nottingham.

THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.—At a recent meeting of the board of directors of the Rockefeller Institute for Medical Research Dr. Rufus I. Cole of the Johns Hopkins Medical School, Baltimore, was appointed director of the hospital of the Rockefeller Institute for Medical Research, and Dr. Christian A. Herter was appointed one of the physicians to the hospital. Work on the hospital buildings is in progress and it is expected that they will be completed and the hospital be ready for opening in November, 1909.

THE MERCURIAL REACTION AS AN ELEMENT OF DIAGNOSIS IN SYPHILIS.

BY F. CURIONI, M.D. TURIN.

SEVERAL times during my practice I have observed the fact, apparently strange, of an intolerance, sometimes relative, sometimes absolute, to mercury presented by some persons. They were individuals who applied to me for advice concerning the treatment of a syphilitic affection which they said they had contracted some months previously and of which on the most diligent examination there were no apparent traces. Some of the syphilitic or pseudo-syphilitic said that they had been examined at the time of the ulcer by medical men who had diagnosed it as syphilitic; others, again, were satisfied by the diagnosis of their chemist, and some, and these unfortunately were not few, had accepted the confirmation of so-called practical friends. In dealing with these cases I was often perplexed what to do. In any case in which I was convinced that the individual was not affected by syphilis but only the victim of an error of diagnosis I advised him not to use specific treatment. In cases more or less suspicious, on the other hand, I have usually prescribed a mild cure for precaution, following in this respect the advice of the greatest specialists. It was among this latter group that, as already stated, I noted a number of cases strangely intolerant to the action of mercury, especially during the first days of treatment. It was in this way that I had the idea that persons affected with syphilis supported mercury much better than normal subjects and I decided to find how the mercury was eliminated in the urine by the healthy and how by the syphilitic.

In order to accomplish my research I chose 30 syphilitic patients and at the same time 20 friends whom I knew were quite free from the disease and submitted them all to mercurial treatment, first having made sure that the kidney was in normal condition in the syphilitic as well as in the healthy. I proceeded in this way. In the morning, always about the same time—that is, at about 11 A.M.—I made an injection of 0·01 of perchloride of mercury in 1 cubic centimetre of distilled water. I collected the urine at first about 7 P.M., again some five or six hours later, and also on the following morning between 8 and 9 o'clock.

With the aid of my friend, G. Fortuna, Doctor in Chemistry, I tested the specific reaction in the three samples of equal volume of urine, using for that purpose the method suggested by Professor Vitali, which is as follows. Place in 200 cubic centimetres of urine previously acidified with a few drops of hydrochloric acid eight grammes of copper wire, well cleaned and cut in small pieces, allowing this to remain for three hours, taking care to agitate the liquid occasionally, then decant the urine and wash the copper well first with distilled water, then with alcohol, and finally with ether. (In doing so it is necessary not to shake the copper too much.) Next place the washed copper on blotting-paper to dry easily; afterwards place in a test-tube quite clean and dry and close this with a plug of cotton; now heat gently the bottom of the tube until the wire becomes slightly brownish, then allow to cool; when quite cold reject the copper and drop in a tiny piece of iodine, heat again gently the bottom of the tube in such manner as not to develop the iodine vapour too strongly. In the presence of a mercurial salt there will be formed on the cool part of the tube small crystals of yellow iodide of mercury and also red bi-iodide. The chemical reaction is easily understood. It is necessary to follow exactly the above directions and to place the tube at the moment of the reaction over something white in order to make the slightest trace of colour visible; to an unaccustomed eye it may be difficult to distinguish between the violet-red vapour of the iodine on the one hand and the straw-yellow of the iodide or the bright-red of the bi-iodide on the other, especially as the quantity is so infinitesimal. It is well to practise beforehand with a weak solution of mercurial salt until one is accustomed to distinguish between the colours. It is most necessary that the tube should be quite dry, because otherwise the iodine vapour dissolving in the small particles of water adhering to the tube will colour them and will in this way interfere with the exact appearance of the reaction. The quantity of iodine

THE LANCET, December 19, 1908.

The Bradshaw Lecture

ON

THE TREATMENT OF WOUNDS.

Delivered before the Royal College of Surgeons of England on Dec. 4th, 1908,

By Sir W. WATSON CHEYNE, Bart., C.B., F.R.S., M.B., C.M. Edin., F.R.C.S. Eng.,
SENIOR SURGEON TO KING'S COLLEGE HOSPITAL, ETC.

Mr. President and Gentlemen,—In taking as the subject of the Bradshaw lecture a critical examination of the present views and methods of treating wounds, I do not think that I need say anything by way of apology for my choice. It is one of the great advantages of lectures such as these that they afford an opportunity not only of introducing new views and observations but also of weighing the theories and practice current at various periods, and of considering how far they accord with definitely ascertained facts and how far we are following the right lines. In a subject such as medicine, where knowledge is still very imperfect, there is a constant oscillation in the views which are current from time to time, and a constant swing of the pendulum of medical opinion in one or other direction, sometimes very extreme and far beyond what is justified by the facts of the case. One has constantly to be on one's guard not to be carried too far by this swing—on the one hand not to discard too hastily the results of previous research and experience, and on the other not to overlook what seems to be sound in the new work. Nowhere is this oscillation of opinion more marked at the present time than in the views founded on experimental and chemical pathology, and more especially in connexion with the new science of bacteriology and the relation of bacteria to the living body. And when the wish was expressed to me that I should take up the subject of the treatment of wounds at the present time I was the less reluctant to do so, seeing that as regards that matter we are just now in one of those extreme oscillations. Whether this swing has gone too far or not is the point which I purpose to consider in this lecture, and it will therefore be advisable in the first place to recall as simply as possible the essential points which relate to the treatment of wounds and to the avoidance of the infective disasters which are ever ready to occur when the attention of the surgeon is relaxed, and in the second place to examine the current views and details of practice with the object of seeing how far they meet the requirements of the case.

What first put Lister on the track of his epoch-marking work was the consideration of the behaviour of a subcutaneous wound as compared with an open one, and his aim from the very first was to place an open wound as far as possible under the same conditions as a subcutaneous one. In the open wound two sets of noxious agencies come into play. In the first place, it is exposed to a variety of mechanical and chemical irritations from the dressings, air, &c., and in the second place to the entrance of infective agents. The surface of the wound, for instance, comes in contact with dressings and is mechanically irritated by movement, &c. And in the attempts to get a wound to heal it may also be irritated by various chemical substances intentionally applied to it, with the result that instead of healing rapidly the tissues are kept in a constant state of irritation, exudation goes on and cells accumulate in the part, the original tissue at the surface is destroyed, and its place is taken by granulation tissue. It is true that if irritation of this kind is but slight healing will nevertheless take place readily, but if it be excessive it may be markedly delayed or actually prevented.

Even where an open wound is stitched up, and thus, as far as these mechanical and chemical causes of irritation are concerned, is converted into a subcutaneous one, very serious troubles much more grave than those alluded to above may arise, due to the entrance of various forms of bacteria into the wound and their growth either in the discharges present in it or in the tissues themselves. It is in reality to these organisms rather than to the other agencies to which I have referred above that the essential troubles in connexion with open wounds are due. Apart from the growth of bacteria, it would be quite easy to minimise the other sources of irritation so that little, if any, delay in healing should result, and in the absence of micro-organisms none of the serious troubles which affect the health or life of the patient or of the part, and which so often used to follow open wounds, would arise. These troubles are practically entirely due to bacterial infection, which occurs as soon as the skin is broken or so injured that it is deprived of its vitality, and the essence of the problem of the treatment of wounds is how to avoid such infection. It was this problem that Lister attacked, and though the main principle on which he proceeded from the first was to prevent as far as possible the entrance of bacteria into wounds he laid much stress on the avoidance of undue irritation of the latter in the process. In fact, his ideal was so to alter the conditions in an external wound as to approach as closely as possible to those in a subcutaneous one. The question for review, then, is how far this ideal is or can be attained and what are the best methods to adopt for this purpose.

1. In the first place, let us consider the question of the exclusion of bacteria from wounds. Lister began by trying to kill the bacteria before or when they came in contact with the wounds, and for this purpose he had recourse to the use of various chemical substances belonging to the class now known as antiseptics. In his earliest work, which had to do with compound fractures, the wounds being already soiled and infected, the method he adopted was to apply undiluted carbolic acid to the wound, with the view of destroying the organisms which had already entered it before the patient came under the notice of the surgeon, and then in order to prevent the access of fresh bacteria he made a paste with the blood contained in the wound and the undiluted carbolic acid, which must have effectually prevented the further entrance and growth of micro-organisms. This original plan was very soon modified, and the constant efforts which he made to improve his methods in the direction of less irritation of the wounds with at the same time efficient exclusion of bacteria will be found detailed in his collected papers.

When I became house surgeon to Lord Lister in Edinburgh in 1876, it occurred to me to test the discharges of the wounds which were under his treatment to see how far the desired result—viz., the exclusion of bacteria—was really attained. At that time it was easy to examine this matter very thoroughly, because in the case of practically every operation a drainage-tube was inserted and was retained for from four to eight days, and as long as the tube was present the dressing was changed daily. At that time the modern methods of staining bacteria had not been introduced and I had, therefore, to devise methods of cultivation in various fluid media. These methods need not be detailed here, but the results so obtained were very definite and entirely coincided with those got in after years by simpler and better methods of cultivation and also by suitable staining of the discharge. The results practically came to this, that as a rule in wounds treated by Lister's methods no organisms were found in material taken from the interior of the drainage-tube during the first few days, but that afterwards one began to find micrococci in a certain proportion of the cases, especially if the dressing had been left unchanged for more than 24 hours or if old epithelium had been allowed to accumulate under the dressing. Suppuration, however, did not necessarily occur, even when these organisms were present. I therefore assumed that they were innocuous organisms, either of a special kind or else the common pyogenic organisms deprived of their infective power by the antiseptics employed. I also came to the conclusion that they spread into the wound under the carbolic gauze dressing by growing in the epithelium, for I found that they were present in the old epithelium at some distance from the edge of the wound in larger numbers and at an earlier period than in the wound itself. It was thus evident that bacteria either did not get into the wounds at the time of the operation, or if they entered they found themselves under such conditions that they were unable to grow, but that at a later period of the case they might spread in, presumably under the protection of the superficial layers of the epithelium, even though the part was covered by a carbolic gauze dressing. After the drainage of wounds was to a large extent given up, it was not so easy to test this matter thoroughly, because mastoid region. Such sudden increase of the deafness or tinnitus is probably not due to rapid extension of the disease itself to other parts of the inner ear but to a temporary local congestion of the vascular system of the labyrinth which may be expected to bear more heavily on areas already diseased. Such conditions, however, if untreated may very possibly lead to a further spread of the disease and a permanent increase of the symptoms.

Apart from the drugs necessary to combat any general dyscrasia from which the patient may be suffering tonics, such as strychnine, phosphorus, or arsenic alone or combined with the iodides, should be advised. This treatment in the first instance should be adopted for a period of some six months with short remissions and then short courses of these medicines extending over six weeks should be advised two or three times a year. In this way the further progress of the disease may be controlled to some extent, though, of course, a cure of already existing lesions cannot be expected. Such treatment, however, often makes the patient more comfortable generally, reduces the tinnitus, and apparently improves the hearing. The improvement is usually more apparent than real and is due probably to the relief of the subjective noises, for the results to the functional tests remain much the same.

Tinnitus and occasionally vertigo may require special treatment, for which purposes the bromides, hydrobromic acid, and drugs of like action are still probably the best. They should be used to give temporary ease pending the more permanent relief from the general and therapeutic measures recommended above. Unfortunately severe tinnitus points to an irritative lesion in the cochlea and vertigo to a similar affection of the walls of the semicircular canals, and consequently the exhibition of such sedatives may meet with little response. A course of Weir-Mitchell's rest cure is said to be often of great benefit in cases of otosclerosis with extremely marked subjective symptoms occurring in neurotic subjects.

Whatever drugs or method of treatment are used the patients should be told that only a prolonged course as above suggested can be expected to be of any service. If they are not disposed to carry this out the sporadic "taking a bottle of medicine" means only useless expense to them.

That the treatment outlined above is vague and empirical must be admitted, yet it is justified by the results obtained, and till a better and possibly specific treatment is discovered should certainly be employed.

Artificial aids to hearing are sometimes useful, but little can or need be said of them. Generally speaking, the more cumbersome and unsightly the more valuable they are, but the best plan is to advise the patient to visit a reliable maker of such instruments and to purchase that which affords him most relief if such aids are desired.

In the past patients afflicted with otosclerosis have often been allowed to drift without appropriate treatment and without warning as to the probable course of the disease so that they have become the prey of the quack and his advertisements, and the object of this paper is to urge the importance of early recognition and early and prolonged treatment of this condition. Though a cure cannot be expected, a certain amount of relief may be obtained and, what is much more important, the further progress of the disease may be controlled or actually arrested. An excellent and most exhaustive monograph, "Die Otosklerose," has been written by Dr. Denker of Erlangen, in which those who are sufficiently interested in the subject will find it ably discussed.

In conclusion, I wish to express my gratitude to Mr. C. A. Parker for the great help he has given me in preparing this paper whilst working with him at the Throat Hospital, Golden-square.

THE MERCURIAL REACTION AS AN ELEMENT OF DIAGNOSIS IN SYPHILIS.

By F. CURIONI, M.D. TURIN.

SEVERAL times during my practice I have observed the fact, apparently strange, of an intolerance, sometimes relative, sometimes absolute, to mercury presented by some persons. They were individuals who applied to me for advice concerning the treatment of a syphilitic affection which they said they had contracted some months previously and of which on the most diligent examination there were no apparent traces. Some of the syphilitic or pseudo-syphilitic said that they had been examined at the time of the ulcer by medical men who had diagnosed it as syphilitic; others, again, were satisfied by the diagnosis of their chemist, and some, and these unfortunately were not few, had accepted the confirmation of so-called practical friends. In dealing with these cases I was often perplexed what to do. In any case in which I was convinced that the individual was not affected by syphilis but only the victim of an error of diagnosis I advised him not to use specific treatment. In cases more or less suspicious, on the other hand, I have usually prescribed a mild cure for precaution, following in this respect the advice of the greatest specialists. It was among this latter group that, as already stated, I noted a number of cases strangely intolerant to the action of mercury, especially during the first days of treatment. It was in this way that I had the idea that persons affected with syphilis supported mercury much better than normal subjects and I decided to find how the mercury was eliminated in the urine by the healthy and how by the syphilitic.

In order to accomplish my research I chose 30 syphilitic patients and at the same time 20 friends whom I knew were quite free from the disease and submitted them all to mercurial treatment, first having made sure that the kidney was in normal condition in the syphilitic as well as in the healthy. I proceeded in this way. In the morning, always about the same time—that is, at about 11 A.M.—I made an injection of 0·01 of perchloride of mercury in 1 cubic centimetre of distilled water. I collected the urine at first about 7 P.M., again some five or six hours later, and also on the following morning between 8 and 9 o'clock.

With the aid of my friend, G. Fortuna, Doctor in Chemistry, I tested the specific reaction in the three samples of equal volume of urine, using for that purpose the method suggested by Professor Vitali, which is as follows. Place in 200 cubic centimetres of urine previously acidified with a few drops of hydrochloric acid eight grammes of copper wire, well cleaned and cut in small pieces, allowing this to remain for three hours, taking care to agitate the liquid occasionally, then decant the urine and wash the copper well first with distilled water, then with alcohol, and finally with ether. (In doing so it is necessary not to shake the copper too much.) Next place the washed copper on blotting-paper to dry easily; afterwards place in a test-tube quite clean and dry and close this with a plug of cotton; now heat gently the bottom of the tube until the wire becomes slightly brownish, then allow to cool; when quite cold reject the copper and drop in a tiny piece of iodine, heat again gently the bottom of the tube in such manner as not to develop the iodine vapour too strongly. In the presence of a mercurial salt there will be formed on the cool part of the tube small crystals of yellow iodide of mercury and also red bi-iodide. The chemical reaction is easily understood. It is necessary to follow exactly the above directions and to place the tube at the moment of the reaction over something white in order to make the slightest trace of colour visible; to an unaccustomed eye it may be difficult to distinguish between the violet-red vapour of the iodine on the one hand and the straw-yellow of the iodide or the bright-red of the bi-iodide on the other, especially as the quantity is so infinitesimal. It is well to practise beforehand with a weak solution of mercurial salt until one is accustomed to distinguish between the colours. It is most necessary that the tube should be quite dry, because otherwise the iodine vapour dissolving in the small particles of water adhering to the tube will colour them and will in this way interfere with the exact appearance of the reaction. The quantity of iodine or need interfere with healing. In the earlier development of the treatment no doubt wounds were considerably irritated by the antiseptics employed, and though that did not go so far as to interfere seriously with healing it led to excessive effusion of serum and necessitated the constant use of drainage-tubes and therefore frequent changes of dressings. Since, however, the carbolic spray has been given up, drainage-tubes have been found to be unnecessary unless in exceptional cases. As a matter of fact, as we have managed matters of late years, no carbolic acid comes in contact with the wounds, and the few drops of sublimate solution which may get in on the fingers, &c., are at once precipitated by the blood and rendered inert.

Apart from interference with healing, excessive irritation of a wound has another bad effect in that it diminishes the resisting power of the tissues, and thereby may enable organisms to take root which otherwise would have been unable to do so. At first sight, in accordance with recent views on the importance of the serum in connexion with resisting power, one might think that an increased flow of serum as the result of the irritation of the wound would be a good thing, but in my opinion the important seat of the resisting power of the body is in the tissues. In the Wightman lecture delivered last May I discussed the defensive arrangements of the body and showed that they resided in the main in the tissues, and that an extremely important point in connexion with the subject was the local differences in the resisting power. I instanced, for example, the different behaviour of the tubercle bacillus in the various bones and joints of the body, and similar differences exist in the case of the pyogenic organisms, according to the part of the body into which they are introduced. Thus we know that if pyogenic organisms enter joints, or bursæ, or lymph spaces they produce much more violent effects than if they are introduced into the peritoneal cavity or into the subcutaneous areolar tissue.

That the living tissues have the power in some way or other of disposing of bacteria was quite early recognised by Lister. He frequently referred to this point in his lectures and showed specimens of urine free from growth which had been obtained simply by cleansing the orifice of the urethra and then passing the urine into sterilised flasks with precautions against the entrance of dust, thus proving that bacteria could not spread along a healthy urethra. He also pointed out the influence of the tissues in preventing the growth of bacteria, as exemplified by the results of operations performed in situations where bacteria cannot be excluded. For example, in operations for hare-lip and cleft palate union by first intention is the rule, provided the tissues are not handled roughly, even though the wounds are bathed with saliva containing large numbers of bacteria.

Now when we have said above that non-pathogenic bacilli or only slightly virulent cocci, or only cocci in small numbers may get into wounds made under Listerian precautions, but under these conditions cannot grow, this failure to grow must clearly be due to the action of the living tissues, for under any of these circumstances growth would occur if the tissues were dead; while the tissues are alive, therefore, they have the power of opposing the growth of bacteria and actually destroy them under favourable conditions.

This action of the tissues in destroying bacteria can be seriously interfered with in various ways in the course of an operation, such as by severe handling and bruising, by the excessive use of antiseptics, or even by washing the wound with plain water, which causes the cells to swell up and lose their vitality, and which is about the worst thing that one can introduce into a wound from this point of view. If under any of these circumstances scrupulous care be not taken to prevent the entrance of pathogenic bacteria into a wound, and if they do enter in any considerable numbers, they can grow more readily and produce more violent effects than in wounds which have been more carefully treated. The experience of years, however, shows that the minute traces of antiseptics which may get into wounds during a properly performed Listerian operation have no appreciable effect in retarding the healing of the wound or in interfering with the resisting power of the tissues.

As a result of the foregoing considerations we see that there are two great points to be kept in mind in treating wounds—namely, (1) the exclusion of bacteria, especially of pathogenic organisms, as far as possible during and after an operation; and (2) avoidance of irritation of the surface of the wound so as not to interfere with healing, nor with the power of the tissues in preventing the growth of any bacteria which may have entered. These are the two essential principles which Lister laid down, and which his immediate pupils have tried to follow. It is interesting indeed to see how Lister, beginning by making the exclusion of bacteria from wounds his main aim and having apparently attained this object, devoted increased attention to the avoidance of irritation of the wounds by the means employed to keep out the bacteria. In fact, in the later period of his work his main efforts were directed to the search, not for more efficient antiseptics, but for equally efficient antiseptics, which would be as little irritating as possible to the wound. It is always the tendency, however, of pupils to out-Herod their masters and thus many of those who took up Listerian treatment went to the extreme of deluging their wounds with carbolic acid and disregarded Lister's second postulate; they thus became well acquainted with the poisonous and irregular action of the antiseptics employed, while at the same time they did not always succeed in avoiding infection. Indeed many, thinking that everything necessary was done if only carbolic acid were employed, forgot the most elementary precautions, especially the cleansing of the hands and the avoidance of reinfection of the hands during the operation. And the result was that sepsis occurred and was often, indeed, more severe than if no antiseptic had been employed, owing to the diminution of the resisting power of the tissues as the result of the irritation of the antiseptic. Curiously enough, many men at the present day who have not been intimately acquainted with Lister's own work think that that was Lister's treatment, and that there is, therefore, some fundamental antagonism between the Listerian principles and the so-called aseptic treatment of the present day. From this extreme travesty of Listerian treatment the pendulum has swung completely round to the other extreme, and the surgeon's efforts have of late been largely directed to avoiding the contact of antiseptic chemical agents with wounds and to injuring the tissues in that way as little as possible. In fact, in the hands of the extremists this point has been carried as far beyond the mean as the abuse of antiseptics was in former times.

As far as I can judge, what led to this swing of the pendulum was, firstly, the excessive use of antiseptics with unsatisfactory results of which I have just spoken; secondly, the constant statements as to satisfactory results obtained by ordinary cleanliness; thirdly, the slow action of antiseptics in destroying spores and their consequent inefficiency under certain conditions; fourthly, various statements as to the difficulty of disinfecting the skin—that is to say, of entirely eradicating the bacteria—which have led many to look on it as a hopeless task; and fifthly, an exaggerated belief in the resisting power of the body.

The first of these points I have just referred to. As regards the second, the opposition to the strict Listerian treatment arose in the first instance and chiefly from surgeons whose operative work dealt essentially with the peritoneal cavity. When, however, these surgeons had to operate on the tissues in other parts of the body they encountered a discouraging amount of suppuration. This is explained by the difference in resisting power in different tissues; evidently the peritoneum has a special power of dealing with bacteria when they are not present in too great numbers or in too virulent a condition.

As to the third point, doubt has arisen as to the efficacy of chemical antiseptics in destroying bacteria, and this is probably a reaction from the idea that antiseptics are instantaneous in their action, which was, of course, the only justification of the use of the spray. Koch was the first to test this matter definitely, and the chief point brought out by his researches was the great difference in the resisting power of actively growing bacteria on the one hand and of spores on the other. In the case of the former, if the antiseptic solution can obtain free access to the organisms, it is only a matter of seconds, or at most of a very few minutes, before they are completely destroyed, provided the solution is sufficiently strong. In the case of spores, on the other hand, the time is much longer, but in any case 1 in 20 carbolic lotion kills them in 24 hours. Where bacteria are surrounded by albuminous material the antiseptic coagulates the albumin and this coagulum may prevent the penetration of the antiseptics, especially of the solution was employed throughout the operation, some two to three pints being utilised.

On the following day the patient's condition was much improved; the drainage-tube was replaced by a gauze plug on the third day and the latter was removed on the fourth day. On the second day after the operation pain in the right side of the chest was complained of and examination led to a diagnosis of "dry pleurisy" at the right base and "pneumonia" involving the left lower lobe; the chest was strapped. The temperature on the third day was 98° and the pulse-rate was 84 per minute. From this date the temperature became irregular, varying from 97° to 102·8°. The bowels were well opened on the third day and the patient enjoyed a fish diet on the eighth day. An increasing area of dulness was detected on the right side of the chest and on the eighteenth day this reached the middle of the scapula posteriorly; a diagnosis of probable "empyema" was made. The signs at the left base gradually cleared up. On the twentieth day an aspirating needle inserted through the ninth right intercostal space in the posterior axillary line withdrew a pint of very offensive pus mixed with gas; accordingly on the following day a portion of the ninth rib was resected. The general pleural cavity was shut off by adhesions, the dome of the diaphragm being considerably raised, and an incision through the latter revealed a large abscess cavity between the liver and diaphragm, from which another pint of pus was evacuated; a large drainage-tube was inserted and the wound partly closed. The pus yielded a pure culture of bacillus coli. As the patient's temperature still continued to fluctuate, subcutaneous injections of anti-coli serum were given on the twenty-fifth and two following days; the temperature assumed a lower level. On the twenty-ninth day the patient received a subcutaneous injection of "bacillus coli vaccine" prepared in the St. Thomas's Hospital clinical laboratory by Dr. L. S. Dudgeon. The temperature reached the normal on the thirty-first day but commenced to rise again on the thirty-fourth day, with the advent of an urticarial (serum) rash. The abscess cavity drained well, the tube being gradually shortened and replaced by one of smaller calibre on the forty-second day; another injection of vaccine was also administered. The temperature continued to fluctuate, but gradually it assumed a lower level, a free discharge of offensive pus continuing. The patient got up and sat in a chair for a few hours on the fifty-third day and received another injection of vaccine on the fifty-sixth day. A troublesome cough developed and the temperature rising the patient had to take to his bed again. Examination of the chest revealed an area of dulness at the right base, reaching as high as the middle of the scapula; breath sounds were absent over this area, vocal fremitus was much diminished, and vocal resonance was not obtainable. Aspiration through the ninth space in the scapular line revealed the presence of pus. On the following day a portion of the tenth rib was resected and another large subphrenic collection of pus was evacuated and the cavity was drained; no communication between this abscess cavity and the former could be demonstrated. A fourth injection of vaccine was given on the sixty-fourth day; the temperature reached the normal level on the sixty-ninth day and remained settled. From this date the patient's general condition rapidly improved. Some 14 days later he was allowed to get up morning and evening. The drainage-tubes were gradually shortened and the amount of discharge rapidly diminished and lost its offensive character. The bowels were kept well open throughout the treatment of the case.

On Jan. 28th, 1908, some three and a half months after the accident, the patient was sent to a convalescent home. A final note on the case reads as follows: "Abdominal wounds quite sound—anterior sinus of chest almost closed, posterior sinus is formed by a narrow track some five inches in length—there is no trouble with the bowels." The patient was again examined on his return from the convalescent home four weeks later; he had put on weight—both sinuses had quite closed and he experienced no discomfort whatever. Some five months after the accident he was allowed to start light work.

This case presents several points of interest. First, the comparative rarity of the accident. Secondly, the difficulties presented in the diagnosis of a "sub-phrenic collection of pus," the physical signs suggesting the presence of an empyema, rather than of pus below the diaphragm. Thirdly, the beneficial effect of the anti-coli serum and bacillus coli vaccine which showed itself in an attempt to stop the spread of the septic process to a great extent, and in the rapid recovery of the patient and rapid healing of the sinuses after evacuation of the pus.

In conclusion, I must express my thanks to Mr. Ballance for his kindness in allowing me to conduct the treatment of the case and for permission to publish these notes.

St. Thomas's Hospital.

A METHOD OF PERFORMING ABDOMINO-PERINEAL EXCISION FOR CARCINOMA OF THE RECTUM AND OF THE TERMINAL PORTION OF THE PELVIC COLON.

BY W. ERNEST MILES, F.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON, S.W., AND
TO THE GORDON HOSPITAL FOR DISEASES OF THE
RECTUM, VAUXHALL BRIDGE-ROAD, S.W.

REMOVAL of the rectum by a combined abdominal and perineal operation was first performed by Czerny in 1884. Since that time several other surgeons, notably Maunsell, Chaput, Gaudier, Challot, Weir, Boechal, Giordino, Quénu, Reverdin, Tuttle, Gant, Mathews, Sir Charles Ball, Wallis, and Aldrich-Blake have employed the method with certain modifications of procedure and with varying success in regard to mortality. So far as I have been able to gather from the literature of the subject, however, the technique of these operators seems to have failed in one important respect—namely, the complete eradication of the *zone of upward spread* of cancer from the rectum, whereby the chance of recurrence of the disease, above the field of operation, can be diminished if not entirely obviated.

Until the close of the year 1906 I had relied solely upon the perineal methods of excision of the rectum, but I found that, even after the most complete and extensive removal possible, recurrence of the disease was a rule to which there were few exceptions. In fact, from a personal experience of 57 such operations, my records showed the disquieting fact that recurrence took place within periods ranging from six months to three years in 54 instances. Moreover, I found that although perfection of technique had reduced the proportion of recurrences in the immediate vicinity of the field of operation, recurrence nevertheless appeared in situations that were beyond the scope of a removal from the perineum. Post-mortem examination showed that these situations were (*a*) the pelvic peritoneum, (*b*) the pelvic mesocolon, and (*c*) the lymph nodes situated over the bifurcation of the left common iliac artery. Bearing these facts in mind I made observations upon the course taken by the upward spread of cancer among patients who had died from inoperable cancer of the rectum and found that the disease invariably extended by continuity of tissue along the parietal attachment of the pelvic mesocolon and in the adjacent parietal peritoneum for about one inch on either side of it as far as the group of lymph nodes situated over the bifurcation of the common iliac artery. In one case the disease extended by continuous spread to the suprarenal capsule of the left kidney. In all the cases thus examined the infiltration of the parietal border of the pelvic mesocolon had caused shrinkage of the pelvic mesocolon itself, whereby the pelvic colon appeared to be bound down, a condition which readily explains the difficulty in obtaining a satisfactory spur when performing colostomy in an advanced case of cancer of the rectum.

From these observations it is obvious that the above-mentioned structures constitute the *zone of the upward spread* of cancer from the rectum, the removal of which is just as imperative as is the thorough clearance of the axilla in cases of cancer of the breast if freedom from recurrence is to be hoped for. The appreciation of this important fact induced me two years ago to abandon the perineal methods of excision of the rectum as inadequate for the purpose of obviating recurrence and to endeavour, by utilising an abdominal method of procedure, to bring the operation of excision of the rectum into line with those methods of performing abdominal apparently wear gloves without disinfecting the hands, looking on the sterilised gloves as a complete safeguard. Rubber gloves no doubt may be depended on so long as they are free from holes, but as they are very liable to be punctured or torn it is somewhat rash to trust to them entirely, and therefore I think that whether gloves are to be worn or not the hands should be as thoroughly disinfected as possible. In fact, in putting on rubber gloves I always fill them with 1 in 2000 sublimate solution and in this way a little of the solution remains in contact with the skin of the hands and continues to disinfect them, a point of some importance should the gloves give way during the course of the operation. As regards this question of wearing gloves I have previously said that the results at the present time are no better than they were by the Listerian method before these extreme precautions were introduced, in fact, could not be better, and therefore gloves are not at all a necessity for those who do not discard the use of antiseptics. But, nevertheless, considering all the possibilities, both of imperfect disinfection of the skin and of possible contamination of the hands during the operation, I regard the use of indiarubber gloves as a valuable addition to the precautions and in the so-called aseptic method they are a necessity. They add security against carelessness in the disinfection of the hands. Besides, apart from carelessness, some surgeon's hands are more susceptible than others to the action of antiseptics and those who are so afflicted are consequently apt to be perfunctory in their antiseptic ablutions, and even where the surgeon does take pains to disinfect his hands the skin under these circumstances becomes rough and is difficult to cleanse thoroughly. Further, if there is any suspicion of having contaminated his gloves during the operation the surgeon need have no hesitation in thoroughly washing in an antiseptic solution, as he might if he were not wearing gloves and his hands were sensitive. Cotton gloves are, I think, a mistake; used alone they do not protect the wound from the hands and used over rubber gloves they prevent the surgeon washing the gloves clean in case they have become contaminated. The only advantage is that they give a better grip.

Formerly instruments were disinfected in 1 in 20 carbolic lotion; now they are universally boiled, and although in most cases the former method is quite effectual boiling is, I think, much more satisfactory, especially in the case of toothed instruments, such as Spencer Wells's forceps, &c. At the same time, boiling in ordinary water tends to blunt sharp instruments, such as knives, scissors, and needles, and in the case of those three I prefer to immerse them for a short time in undiluted carbolic acid and then in 1 in 20 carbolic solution in place of boiling them.

With regard to disinfection by boiling, it must be remembered that boiling water is not instantaneous in its action any more than carbolic acid is. One frequently finds that nurses have the most profound belief in the rapid action of boiling as a disinfectant. An instrument falls on the floor, the nurse picks it up and says that she will sterilise it in a minute; and this is no mere figure of speech: she is actually back in a minute with the instrument, all that she has done being either to dip it into boiling water or to throw it into the steriliser and pick it out almost immediately. This, of course, is much too rapid for disinfection, and indeed the length of time required for properly disinfecting an instrument by boiling raises a difficulty in cases where it has not been put out beforehand and where it is wanted in a hurry during an operation. In that case I believe the quickest and safest plan is to immerse it in undiluted carbolic acid for a minute or two and then to place it in 1 in 20 carbolic lotion till it is required.

Among other things which come in contact with a wound during an operation, and which may convey infection to it, I may specially mention sponges. I think it will be generally admitted that for the purpose of removing blood from wounds marine sponges are superior to swabs, and yet the great majority of surgeons have given up their use. This is, I believe, in the main due to the conviction which seems to have become deeply rooted, that heat is the only dependable method of disinfection, and marine sponges are ruined by heat; and also to the terror which some people have of antiseptic solutions. 1 in 20 carbolic acid will destroy bacteria and their spores in 24 hours, even in an albuminous fluid; if marine sponges are kept in this lotion for a week they may certainly be depended upon to be completely disinfected. This is not a matter of theory but of experiment. For my part I always use marine sponges. They are thoroughly washed and immersed in 1 in 20 carbolic acid for at least a week before use. It is quite easy to wash out the carbolic acid from the sponges subsequently either in a weak sublimate solution or in sterilised salt solution. I have never seen any reason to reject marine sponges, either from the point of view of asepsis or from that of irritation by antiseptics, and as a method of drying a wound there is no comparison between them and swabs. Apart from the greater usefulness of marine sponges, I object to swabs in aseptic cases, because, as they do not absorb fluid readily, there is more rubbing and consequent disturbance of the surface of the wound when swabs are employed, especially if they are used dry; and further, except in specially made swabs, threads are apt to be left behind in the wound, which may form a nidus for the development of bacteria, if any have entered during the operation. The importance of the latter point is by no means inconsiderable. For example, we find in the early experiments on tetanus that infection could not be brought about at all readily unless the bacilli were attached to some inert substance such as a silk thread. If injected subcutaneously in small numbers in suspension in fluid, no effect was produced, while silk threads soaked in a suspension of bacteria and placed beneath the skin led to the desired result. I venture to think that the way in which marine sponges have been thrown aside, and swabs, whether wet or dry, have been substituted, is regrettable and introduces an unnecessary complication into the operation.

We may say, therefore, that as regards the preliminary disinfection, heat, especially in the form of boiling, is the most certain and best method of sterilisation, but we cannot do without chemical antiseptics for the disinfection of the skin, and of various articles such as marine sponges, which are of great use during the operation.

The *second point*—and it is one of the greatest importance—is to avoid soiling of instruments, hands, and consequently of the wound itself during the course of the operation. No doubt bacteria are constantly falling into the wound from the air during the operation, but it is well to diminish the number that may get in as much as possible, while it is important not to introduce masses of organisms, especially of pathogenic ones, as may be done if the hands of the operator touch surrounding objects which are not free from bacteria and are then put into the wound, or in many other ways which an observant surgeon will notice, but which are too numerous to mention. We must therefore so arrange matters that in the course of the operation there shall be as little chance as possible of accidental introduction of masses of bacteria into the wound, whether by the surgeon's hands or instruments, or in any other way.

The first thing that is done in order to diminish this risk is to surround the area of operation widely by aseptic cloths. About this point there seems to be no question in any of the plans adopted; the usual method is to cover the blankets, skin, &c., over a wide area in the vicinity with towels which have been sterilised by superheated steam. Personally, I prefer to sterilise the towels by boiling them. I think it is a much more certain way of carrying out the disinfection, especially when we see the small sterilising machines which are on the market at the present time and which are so much used, and realise that they cannot sterilise materials placed in them, especially when the latter are packed at all tightly. From the point of view, then, of complete sterilisation I much prefer to boil the towels; the only advantage of the dry towels is the question of keeping the patient dry, but as in any case mackintoshes are first applied over the surrounding area, the moisture of the towels need not penetrate to the patient.

Another objection which I have to *dry* sterilised towels is that dust is constantly falling on them during the course of an operation, and if the operation is a prolonged one a comparatively thick layer of dust may in course of time collect on the surface, and may be transported into the wound by instruments which have been laid on the towels or by the fingers of the operator. For this reason, after boiling the towels, I have them immersed in an antiseptic solution, usually 1 in 2000 corrosive sublimate, and the sublimate is not wrung out to any extent before spreading out the towels. The result is that any dust which falls on these towels comes in contact with an antiseptic solution, and as regards non-spore-bearing organisms such as the cocci, which are the chief enemies to be guarded against, disinfection

A NOTE ON THE TREATMENT IN A CASE OF ARTHRITIS DEFORMANS.

BY FREDERICK BOOTH, M.D. ABERD.

THE treatment of arthritis deformans is at the present time so unsatisfactory that I have no doubt anything new which has proved successful even in one case will be of interest to the readers of THE LANCET. As there are several recognised varieties of the disease which are probably produced by different causes it will be necessary before describing the treatment to give a brief outline of the case to which I refer.

The patient, a female, aged 29 years, had previously to the attack always enjoyed good health and was strong, robust, and of a cheerful temperament, and there was no history of gout or rheumatism in the family. In January, 1907, she had a mild attack of influenza followed by slight swelling of both ankle-joints, which was accompanied by considerable pain felt especially during the night. In February swelling and pain occurred around the first metacarpophalangeal joint of the right hand, the symptoms coming on suddenly, lasting for a few days, and then as quickly disappearing, these attacks recurring at first at long intervals but as time went on more frequently, lasting longer, and leaving considerable thickening of the tissues around the joint. Then the other joints, gradually, one after another, became affected in the same way and somewhat in the following order—namely, the shoulder, the knees, the elbows, the hips, the jaws, and the spine, until there was hardly one joint in the body which was not more or less attacked by the disease. At first between the attacks there was very little impairment of movement or sign of the interior of the joint being affected, but in the latter stages effusion, especially in both knee-joints, took place. At an early stage of the disease neuralgia appeared, first in the ulnar and circumflex nerves, and gradually extended over the body, the pain and tenderness, though not as a rule severe, being very persistent. Constipation was marked from the onset and the motions became offensive and slimy, although up to that time the bowels had been quite regular. The temperature, though at first only occasionally raised above normal, became persistently so in October, when it generally ranged between 100° F. in the morning and 102° in the evening. Emaciation and anæmia were only slightly marked until the fever became constant, when both increased with moderate rapidity. The urine throughout the attack was normal.

At the commencement of the illness aspirin gave great relief, but this eventually lost to a great extent its good effect, whilst other drugs or external applications, though sometimes relieving the pains, had no effect whatever in stopping its progress. On Jan. 24th I advised the washing out of the colon daily with a four and a half feet œsophageal tube, using three quarts of warm water in which two tablespoonfuls of Epsom salts were dissolved, the tube being connected with a Higginson's syringe and the water pumped into the intestines as it was gradually inserted, no difficulty being experienced in thus using it. The lower bowel was by this means thoroughly irrigated and the motion which was for the first fortnight offensive and contained a large quantity of mucus gradually improved and became normal. In order to relieve and to disinfect the small intestine a tablespoonful of castor oil was given every morning by the mouth and two compound beta naphthol tabloids B.W. were given three times a day. Nova aspirin was given in 10-grain doses twice a day as the symptoms improved, and later hæmatogen was found to be very beneficial in relieving the anæmia. From the commencement of the washing out of the colon, as above described, the whole of the symptoms improved rapidly, and in a few days the fever and neuralgia had disappeared, the appetite had improved, and the emaciation was less marked. The joints also gradually became less painful and tender and the swelling and effusion slowly subsided. The intestinal lavage was kept up daily until March 14th, then three times a week until May 17th, when the patient went to Buxton, where she is now under the care of Dr. C. W. Buckley, who informs me that the lavage as above described has been gradually reduced to once a week, and the only joint to any extent now affected is the knee, which is improving under subcutaneous injections of fibrolysin.

The above case clearly proves that the disease in this instance was produced from poison generated in the intestinal canal mainly in the large gut. That the small intestine was also infected by the poison was, I think, shown by the fact that when the beta naphthol was not given the motions became more offensive and the improvement for the time was slower. The almost instantaneous disappearance of the neuralgia and rapid diminution of the emaciation were, I think, to be accounted for by the fact that about one-fourth of the water introduced by the tube was retained and this would no doubt be rapidly absorbed and together with the improved appetite would help to fill up the tissues and the salts contained in it would, as I have often found, relieve the neuralgic pains.

St. Anne's-on-the-Sea.

STREPTOCOCCAL ("SEPTIC") THROATS.

BY J. O. HOLLICK, M.B. DURH., M.R.C.S. ENG., L.R.C.P. LOND.,
MEDICAL OFFICER TO THE MIDLAND COUNTIES IDIOT ASYLUM.

IN April, 1908, an outbreak occurred at the Midland Counties Idiot Asylum of a pharyngitis and tonsillitis of an infectious nature, at first thought to be due to the Klebs-Löffler bacillus. Subsequent examination of swabs from the infected throats showed, however, an absence of diphtheria and diphtheroid bacilli but plentiful growth of both streptococci and staphylococci. The examination of swabs was kindly undertaken by Professor R. F. C. Leith, of the pathological department of the University of Birmingham, to whom my best thanks are due for most careful and repeated examinations. The epidemic at first occurred in the nursing staff, a female nurse showing signs of the trouble. It rapidly spread to other nurses on the female side and then to the male nurses, after which several of the male inmates were affected.

The general symptoms are as follows. There is a feeling of malaise, pains in the back and in the neck up to the occiput, and violent headache in a few cases; no vomiting or other abdominal symptoms. The evening temperature often rose to 104° F. and the morning temperature to 100°. With regard to the throat symptoms, there were slight soreness on one or both sides and difficulty of swallowing; the submaxillary and glands adjacent to the angle of the jaw and in the triangles of the neck were slightly enlarged and tender. On inspection one or both tonsils showed creamy-white secretion with angry-looking areola of inflammation extending to the anterior pillar of the fauces and the uvula was often swollen and intensely œdematous. No points of follicular exudation from the tonsils were noticeable. The urine was febrile and in some cases showed a slight trace of albumin, disappearing, however, in from two to three days; no casts or blood were present. The exudation rarely extended beyond the anterior pillars of the fauces to the front nor beyond the posterior pillars behind, but much muco-purulent secretion was observed to exude from the lymphoid follicles over the vault of the pharynx; and signs of nasal obstruction pointing to a general engorgement of the lymphoid tissue around the posterior nares and extending through the nares anteriorly were often evident. The exudate in no case extended over the soft palate or uvula. In from two to four days, according to the severity of the infection, the symptoms and local signs decreased, the glandular swelling and tenderness in the triangles of the neck and at the angle of the jaw remaining for some days or weeks after the clearing up of the throat symptoms. In connexion with this epidemic two cases of cutaneous erysipelas of the foot and leg occurred: both patients had slight abrasions of the skin previously, one of the skin between the toes and one of the skin over the dorsum of the foot. The temperature of both cases at once rose to 103° and 104° respectively. 20 cubic centimetres of antistreptococcic serum (Lister Institute) were administered subcutaneously into the skin over the abdomen. A marked fall of temperature occurred in each case during the next 24 hours, with, however, little abatement of the local signs of cutaneous inflammation; neither case suppurated, but convalescence was tardy owing to extremely slow subsidence of local inflammatory signs. Several of the patients with the throat symptoms and glandular enlargements showed a tendency to relapse if allowed to get up within too short a period of subsidence of apparently wear gloves without disinfecting the hands, looking on the sterilised gloves as a complete safeguard. Rubber gloves no doubt may be depended on so long as they are free from holes, but as they are very liable to be punctured or torn it is somewhat rash to trust to them entirely, and therefore I think that whether gloves are to be worn or not the hands should be as thoroughly disinfected as possible. In fact, in putting on rubber gloves I always fill them with 1 in 2000 sublimate solution and in this way a little of the solution remains in contact with the skin of the hands and continues to disinfect them, a point of some importance should the gloves give way during the course of the operation. As regards this question of wearing gloves I have previously said that the results at the present time are no better than they were by the Listerian method before these extreme precautions were introduced, in fact, could not be better, and therefore gloves are not at all a necessity for those who do not discard the use of antiseptics. But, nevertheless, considering all the possibilities, both of imperfect disinfection of the skin and of possible contamination of the hands during the operation, I regard the use of indiarubber gloves as a valuable addition to the precautions and in the so-called aseptic method they are a necessity. They add security against carelessness in the disinfection of the hands. Besides, apart from carelessness, some surgeon's hands are more susceptible than others to the action of antiseptics and those who are so afflicted are consequently apt to be perfunctory in their antiseptic ablutions, and even where the surgeon does take pains to disinfect his hands the skin under these circumstances becomes rough and is difficult to cleanse thoroughly. Further, if there is any suspicion of having contaminated his gloves during the operation the surgeon need have no hesitation in thoroughly washing in an antiseptic solution, as he might if he were not wearing gloves and his hands were sensitive. Cotton gloves are, I think, a mistake; used alone they do not protect the wound from the hands and used over rubber gloves they prevent the surgeon washing the gloves clean in case they have become contaminated. The only advantage is that they give a better grip.

Formerly instruments were disinfected in 1 in 20 carbolic lotion; now they are universally boiled, and although in most cases the former method is quite effectual boiling is, I think, much more satisfactory, especially in the case of toothed instruments, such as Spencer Wells's forceps, &c. At the same time, boiling in ordinary water tends to blunt sharp instruments, such as knives, scissors, and needles, and in the case of those three I prefer to immerse them for a short time in undiluted carbolic acid and then in 1 in 20 carbolic solution in place of boiling them.

With regard to disinfection by boiling, it must be remembered that boiling water is not instantaneous in its action any more than carbolic acid is. One frequently finds that nurses have the most profound belief in the rapid action of boiling as a disinfectant. An instrument falls on the floor, the nurse picks it up and says that she will sterilise it in a minute; and this is no mere figure of speech: she is actually back in a minute with the instrument, all that she has done being either to dip it into boiling water or to throw it into the steriliser and pick it out almost immediately. This, of course, is much too rapid for disinfection, and indeed the length of time required for properly disinfecting an instrument by boiling raises a difficulty in cases where it has not been put out beforehand and where it is wanted in a hurry during an operation. In that case I believe the quickest and safest plan is to immerse it in undiluted carbolic acid for a minute or two and then to place it in 1 in 20 carbolic lotion till it is required.

Among other things which come in contact with a wound during an operation, and which may convey infection to it, I may specially mention sponges. I think it will be geneally admitted that for the purpose of removing blood from wounds marine sponges are superior to swabs, and yet the great majority of surgeons have given up their use. This is, I believe, in the main due to the conviction which seems to have become deeply rooted, that heat is the only dependable method of disinfection, and marine sponges are ruined by heat; and also to the terror which some people have of antiseptic solutions. 1 in 20 carbolic acid will destroy bacteria and their spores in 24 hours, even in an albuminous fluid; if marine sponges are kept in this lotion for a week they may certainly be depended upon to be completely disinfected. This is not a matter of theory but of experiment. For my part I always use marine sponges. They are thoroughly washed and immersed in 1 in 20 carbolic acid for at least a week before use. It is quite easy to wash out the carbolic acid from the sponges subsequently either in a weak sublimate solution or in sterilised salt solution. I have never seen any reason to reject marine sponges, either from the point of view of asepsis or from that of irritation by antiseptics, and as a method of drying a wound there is no comparison between them and swabs. Apart from the greater usefulness of marine sponges, I object to swabs in aseptic cases, because, as they do not absorb fluid readily, there is more rubbing and consequent disturbance of the surface of the wound when swabs are employed, especially if they are used dry; and further, except in specially made swabs, threads are apt to be left behind in the wound, which may form a nidus for the development of bacteria, if any have entered during the operation. The importance of the latter point is by no means inconsiderable. For example, we find in the early experiments on tetanus that infection could not be brought about at all readily unless the bacilli were attached to some inert substance such as a silk thread. If injected subcutaneously in small numbers in suspension in fluid, no effect was produced, while silk threads soaked in a suspension of bacteria and placed beneath the skin led to the desired result. I venture to think that the way in which marine sponges have been thrown aside, and swabs, whether wet or dry, have been substituted, is regrettable and introduces an unnecessary complication into the operation.

We may say, therefore, that as regards the preliminary disinfection, heat, especially in the form of boiling, is the most certain and best method of sterilisation, but we cannot do without chemical antiseptics for the disinfection of the skin, and of various articles such as marine sponges, which are of great use during the operation.

The *second point*—and it is one of the greatest importance—is to avoid soiling of instruments, hands, and consequently of the wound itself during the course of the operation. No doubt bacteria are constantly falling into the wound from the air during the operation, but it is well to diminish the number that may get in as much as possible, while it is important not to introduce masses of organisms, especially of pathogenic ones, as may be done if the hands of the operator touch surrounding objects which are not free from bacteria and are then put into the wound, or in many other ways which an observant surgeon will notice, but which are too numerous to mention. We must therefore so arrange matters that in the course of the operation there shall be as little chance as possible of accidental introduction of masses of bacteria into the wound, whether by the surgeon's hands or instruments, or in any other way.

The first thing that is done in order to diminish this risk is to surround the area of operation widely by aseptic cloths. About this point there seems to be no question in any of the plans adopted; the usual method is to cover the blankets, skin, &c., over a wide area in the vicinity with towels which have been sterilised by superheated steam. Personally, I prefer to sterilise the towels by boiling them. I think it is a much more certain way of carrying out the disinfection, especially when we see the small sterilising machines which are on the market at the present time and which are so much used, and realise that they cannot sterilise materials placed in them, especially when the latter are packed at all tightly. From the point of view, then, of complete sterilisation I much prefer to boil the towels; the only advantage of the dry towels is the question of keeping the patient dry, but as in any case mackintoshes are first applied over the surrounding area, the moisture of the towels need not penetrate to the patient.

Another objection which I have to *dry* sterilised towels is that dust is constantly falling on them during the course of an operation, and if the operation is a prolonged one a comparatively thick layer of dust may in course of time collect on the surface, and may be transported into the wound by instruments which have been laid on the towels or by the fingers of the operator. For this reason, after boiling the towels, I have them immersed in an antiseptic solution, usually 1 in 2000 corrosive sublimate, and the sublimate is not wrung out to any extent before spreading out the towels. The result is that any dust which falls on these towels comes in contact with an antiseptic solution, and as regards *non-spore-bearing organisms* such as the cocci, which are the chief enemies to be guarded against, disinfection

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

X Ray Examination of the Urinary Tract.

A MEETING of this section was held on Dec. 8th, Mr. WARRINGTON HAWARD, the President, being in the chair.

Dr. W. IRONSIDE BRUCE read a paper on a system of X Ray Examination of the Urinary Tract. He said that, taking the x ray as produced and looking upon it as a source of light emanating from a point referred to as the anode of the tube, the radiogram was a shadow cast upon a photographic plate of those parts of the body that were opaque to the x ray. In dealing with ordinary light shadows might give false impressions of the objects which cast them, and in the case of x ray shadows of the renal region that fact claimed specially to be borne in mind. If these x ray shadows were to be used as a means of recognising any existing abnormality it was surely necessary as a preliminary that an accurate knowledge of the normal x ray appearance presented by this part should be acquired. In order to gain this knowledge it was of the greatest importance that the shadow secured of the part should always be the same. In other words, the anode of the tube should always bear the same relation to the part at the time of irradiation. In his method the anode of the tube was readily and easily placed in an accurate anatomical relation to the part to be examined by means of a very simple mechanical contrivance. In the case of the renal region it was placed immediately below the spine on the second lumbar vertebra. In every case this relation between the anode of the tube and the spine of the second lumbar vertebra was maintained and, since the kidneys and the ureters usually bore a definite relationship to the bones of the part, a radiogram showing up these structures would demonstrate the shadow relationship which they bore to the bones. In order to secure a proper knowledge of these relationships the pelves of the kidneys and the ureters of a post-mortem subject were injected with an emulsion of bismuth. A radiograph was then secured of the renal region of the subject, the anode of the tube being in the usual relation to the second lumbar vertebra. By means of the radiogram thus secured the shadow relationship of the kidneys, right and left, and of the ureters was worked out. The position of the subject was also of great importance. The patient was placed, lying face downwards with his arms by his side, on a canvas-topped couch under which the tube was arranged, and in order to restrict, so far as it was possible to do so, the movements of the diaphragm and consequently of the kidneys, a pad or compressor was placed under the abdomen with the whole weight of the patient resting upon it. The compressor pushed the abdominal contents away from the renal area and allowed the more perfect illumination of these parts. It was often difficult to secure a radiogram of good quality, sometimes on account of the density of the subject and sometimes owing to the vagaries of the patient. The latter were usually overcome by frequent examinations or by administration of an anæsthetic. With regard to the first-named cause it was not always the most obese subjects that were the cause of failure; more often it was the stout subject with considerable muscular development. The use of an abdominal compressor combined with frequent examination and effective evacuations of the intestine, usually resulted, however, in a radiogram of good quality, even in the most obese subject. A radiogram of good quality should show the following points: it should be absolutely symmetrical; the lumbar vertebra should be sharp and distinct in outline; the margin of the psoas muscle easily made out; the twelfth rib well defined; and the outline of the kidney on either side discernible. If such a radiogram were secured there was no reason why a positive or negative diagnosis might not be absolutely relied upon, but in a case where the radiogram was not up to the standard it was the duty of the radiographer to state this fact, so that the diagnosis, positive or negative, might be valued at its true worth. In order to bring renal examinations to a successful conclusion it was essential that the examination should not be carried out in a hurried manner, for not only was it necessary to have the intestine properly emptied but time should be allowed for re-examination, not once but two or three times if necessary. It was often insisted upon that the radiographer should be in possession of all the clinical facts of the case before making his examination. Although a knowledge of the clinical history was desirable, yet it was much better that at the time of examination the only knowledge possessed of the case should be that it was one of supposed calculus in the kidney or ureter. By approaching the case in that manner the radiogram secured could be viewed with an entirely unbiassed mind, and an examination in every case of the whole of the urinary tract became absolutely necessary. A provisional diagnosis having been made radiographically, the clinician could then compare his conclusion with that arrived at by the x ray examination. Thus the value of clinical observations in such cases was considerably increased. Further, it was of the utmost importance that neither the clinical nor the x ray evidence should be put in a place of first importance. The radiographer was wrong who stated that x ray evidence was infallible and, on the other hand, the clinician was surely equally wrong who advocated operation in the face of strong x ray evidence to the contrary. It was always advisable, if possible, to bring one into line with the other. Any increase in the size of the outline of the kidney, when observed in a case of suspected renal calculus, might assist the diagnosis—for example, in the case of a boy who had had attacks of renal colic associated with pus in the urine. Calculus was suspected but on x ray examination the outline of one kidney was markedly increased in size and no opacity was to be made out suggesting the presence of calculus. From an x ray point of view the diagnosis in this case was tuberculous kidney with renal colic from the passage of pus and débris through the ureter. As a matter of fact, such was the condition of affairs on post-mortem examination. If, moreover, there was more than one calculus present in a case this fact might be noted and the position of the calculus or calculi in relation to the pelvis or the cortex of the kidney might be indicated. The condition of the sound kidney, provided the outline of it could be made out, might also be deduced from the size of the shadow cast by it. In conclusion, he trusted that from what he had shown them of the work of the radiographer in connexion with the diagnosis of renal calculus, they would appreciate some of the difficulties with which he was faced and that they would see that he had striven to some purpose to remove this method of investigation from the realm of mere mechanics to a branch of the profession that must be recognised as a permanent and essential factor in the accurate diagnosis of disease of the urinary system.

The paper was discussed by Dr. G. H. ORTON, Mr. W. G. SPENCER, and Dr. N. S. FINZI, after which Dr. BRUCE replied.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

The Treatment of Rheumatism.

A MEETING of this section was held on Dec. 1st, Dr. F. H. BURTON BROWN, the President, being in the chair.

Professor RALPH STOCKMAN read a paper upon the Treatment of Rheumatism. He showed and analysed a large number of charts illustrating the prompt fall of temperature which resulted when the patient came under the influence of salicylate of sodium. When the initial fall was partial or slow, an increase in the amount of the drug would usually cause the temperature to fall completely. He also showed charts illustrating the action of drugs closely allied in pharmacological composition—salicin, salicylate of methyl, &c. In one group of cases of rheumatism the synovial membranes of the joints were alone or principally involved; in a second group of cases, which were more chronic and less amenable to treatment, there was much involvement of the surrounding fibrous structures, the tendons, and fasciæ. In the latter much larger doses might be required.

Dr. D. B. LEES read a paper in which he maintained that the present treatment of acute rheumatism was unsatisfactory and inadequate because, failing completely to arrest the disease, it despaired of any beneficial influence on the heart and was content to alleviate the painful arthritis. He advocated the use of large quantities of salicylate of sodium, with infective material, they act as irritants and are really nothing more or less than the old setons. I would, therefore, strongly beg for a reconsideration of this question of drainage and for the resumption of drainage by tubes instead of gauze, certainly in all cases where sepsis is present. I have repeatedly seen cases of intractable sinuses where all that was required to obtain healing was to leave out the gauze plug and keep the orifice of the sinus open for a few days by means of a small drainage-tube.

Coming now to the *third point*, viz., the question of preventing infection of the wound after the operation is completed, I think that we have here the most important difference between the extremists and the Listerian school. Lister from the first pointed out that an essential part of the treatment was to prevent the possibility of infection of the wound after the completion of the operation. Now infection of the wound after the operation takes place by the growth of bacteria in the blood and serum after they escape from the wound and in the dead epithelium on the surface of the skin, and their subsequent penetration into the wound along stitch tracks, drainage openings, &c. With the view of avoiding this growth, Lister arranged that the discharges from the wound should be received into dressings which contain an antiseptic in such amount that when dissolved by the discharge it will render the latter an unsuitable soil for the growth of bacteria. As was pointed out in a paper read by Lister at the Medical Society of London some years ago, it is not necessary that the amount of antiseptic thus communicated to the discharge should be very great. All that is wanted is to add enough antiseptic to the discharge to inhibit the growth of bacteria, not to produce a solution strong enough to kill them; and by following that principle it is not necessary to put on dressings containing antiseptics of a character or in sufficient amount to irritate the skin. It is true that some skins are more irritable than others, and that a rash may occur in some cases under a very mild antiseptic dressing, but with the antiseptics which are now used this is of comparatively rare occurrence, and where necessary can be avoided by placing a layer of plain sterilised gauze next the skin beneath the antiseptic dressing. It may be noted that in any case the antiseptic in the dressing does not get into the wound; it is merely placed there with the object of preventing bacteria growing in the discharge and reaching the wound.

Nowadays surgeons are using to a large extent dressings which have been heated and which no doubt in many cases are really sterile, but which do not contain any antiseptic. In passing I may remark that the sterility of these dressings is by no means certain in all cases, for one has only to look at the small machines which are often used in private work, and the way in which dressings are tightly packed into them, to realise that no proper sterilisation can have taken place. The action of such a dressing is merely that of a filter against the dust of the air, just like the plug of wool in a cultivation tube. The discharge soaks into the dressing, and till it comes near the surface of the dressing it may remain sterile. That, however, will only be the case if the skin has been really thoroughly sterilised and if no bacteria have fallen on the skin or the dressings before they are applied. But, in any case, as soon as the discharge reaches the surface of the dressing bacteria will grow in it and rapidly spread through it and reach the wound, unless, indeed, the blood has in the meantime become so concentrated by drying that it is no longer a suitable cultivating medium.

When we reflect that an organism dividing three times an hour, which is a fair average, will give rise to something like 33 million bacteria in 12 hours one can have some idea how quickly the organisms may reach a wound once the discharge has come to the surface of a plain sterilised dressing. Although no doubt after 24 or 48 hours these bacteria can no longer penetrate into the wound and cause deep-seated trouble they may quite well spread along the stitches and give rise to the stitch abscesses, which seem to be not at all uncommon in the practice of surgeons who use these dressings. These stitch abscesses have, in my opinion, been erroneously attributed to imperfect sterilisation of the stitch material or to imperfect disinfection of the skin. I say erroneously because, using antiseptic dressings, I have practically no experience of them, and the conclusion which follows from that fact is that it is from the want of antiseptic in the dressings and the consequent growth of bacteria rather than from the other causes mentioned that these stitch troubles arise. To carry out the purpose of this dressing a large mass must be put on, and not the small pieces that one so often sees used. If it fails in its object it does harm instead of good, for it interferes with the drying up of the discharge and, keeping it warm and moist, favours the development of bacteria in it. This plan was tested long ago by Lister and was given up as being unsatisfactory.

If I were to go over to the extreme party and abandon the use of antiseptics—which I have no intention of doing—I should not apply any dressing to the wound at all. If the wound is left open and protected from direct contact with septic materials the blood and serum which ooze out in the first instance will very soon dry up and form a scab which will prevent infection of the interior, and if I were dressing wounds in that way I should build up a mass of aseptic dressings on each side of the wound and then fix a thin layer of wool or gauze over the surface, but not touching the wound, so as to protect it from dust. Where wounds can be completely closed from end to end I think the great majority would do perfectly well if treated in this way, and probably better than if covered with plain sterilised dressings, but where drainage has to be provided, as is, of course, the case in some operations, such as in some extensive breast operations in fat people, in draining joints, &c., the problem is different, and there I think that it is essential that the dressing should contain some antiseptic if one wishes to be certain of the result.

To sum up the criticism which I have to make on the most recent ideas on the treatment of wounds, it is that the pendulum has swung too far in the direction of the avoidance of antiseptics, and that the reasonable use of all the means at our disposal for securing asepticity of wounds will furnish more constant results. The chief point to which I take exception is the employment of dressings which do not contain an antiseptic in sufficient amount to render the discharges which flow through them unsuitable for the growth of bacteria. And a second point which I also think is very important is the absence of antiseptic solutions during the operation in which hands, instruments, &c., may be washed from time to time to insure a continued asepsis. A third point which I think is a retrograde step is the substitution of gauze plugs for drainage-tubes, more especially for the drainage of abscesses and sinuses. Minor points are the use of swabs instead of marine sponges and the avoidance of catgut. This extreme view has, however, done good, especially in the way of directing attention to the value of heat as a disinfectant for various purposes in connexion with operations. There is no doubt that the sterilisation of instruments, towels, &c., by boiling and of dressings by a current of superheated steam adds very distinctly to the certainty of the results. It has also done good by calling attention to the importance of diminishing the amount of dust which may get into wounds at the time of the operation, although some of these precautions have been given an importance which they do not deserve.

It always seems to me—and I say this from a large experience in bacteriological work—that the attempt to treat wounds without any antiseptics is a very unnecessary complication. In the first place, it is ever so much more difficult to secure asepticity of a wound under such circumstances than if one takes advantage of antiseptics, and in the second place it requires a man who is especially skilled and experienced in bacteriological work to bear in mind the various loopholes which have to be guarded against in order to obtain a constant aseptic result. I say that bacteriological experience is necessary because the surgeon has to concentrate his attention on the object of the operation rather than on the aseptic technique, and in order to carry out the object of the operation satisfactorily and at the same time without the risk of sepsis the aseptic technique must be practically automatic. Therefore, if he has to be thinking all the time not only of the object of his operation but of the various loopholes which may arise and which he must most carefully avoid, seeing that he has no antiseptic materials at hand with which to rectify mistakes, one or other point must suffer; either his operation may not be carried out as he would desire it or his aseptic technique is apt to be faulty. I confess that I can see no reason for this great dread of a drop of antiseptic material getting into the wound; I can neither case was that value fully explicable by their present knowledge.—Dr. A. C. GURNEY (Eastbourne) was of opinion that one important therapeutical point not touched on in Dr. Brodribb's paper was the fact that in sea bathing there was a mechanical stimulation of the skin by the impact of the spray or surf and the movement of the water which gave it an important advantage over the brine baths of inland spas in a certain class of cases.—Dr. C. W. BUCKLEY (Buxton) considered that the cause of sea water baths for medicinal purposes would not be advanced by the argument that since sea water contained more dissolved substances than some mineral springs it must be more potent. The constituents to which mineral waters owed their undoubted efficacy had not yet been definitely ascertained.

Mr. W. J. MIDELTON (Bournemouth) read a paper on the Treatment of Rheumatic Affections by Counter-irritation of the Spine, in which he said that he was firmly convinced that continuous counter-irritation in the neighbourhood of the cervical and lumbar enlargements of the spinal cord was a powerful means not only of producing a beneficial effect on the nervous system but also of eliminating germs and toxins. He gave a short history of the method and mentioned other practitioners who had adopted it with success. He had treated 27 cases of polyarticular rheumatoid arthritis in both the early and late stage, three cases of paralysis, and two of hysteria by this method with marked success. He read notes of four of his more recent cases. He showed a patient who had been restored to health and freedom of movement by this means under the care of Dr. S. G. Champion and read notes of other cases treated by him and Mr. A. B. Batley.—Dr. A. P. LUFF (London) stated that the results of his experience of applying blisters to the region of the spine in the treatment of various diseases of the joints did not compare altogether favourably with other methods of treatment.—Mr. W. ARMSTRONG (Buxton) said, holding the view that in all cases of arthritis there was more or less interference with the nerve-nutrition of the joints, he had for the last 12 years given special attention to the treatment of the so-called "joint centres" in the cord. At first the applications were of mustard bran, acetic acid, and other counter-irritants; later the blistering treatment advocated by Mr. Midelton, which he had used thoroughly in 16 cases, all severe examples of definite rheumatoid arthritis, more or less improvement taking place in every instance. For the last four years he had substituted the electric cautery. The applications, which should not make skin lesions, were made to the sides of the cervical enlargement in affections of the upper limbs and of the lumbar enlargement where the lower extremities were involved. He did not put this method forward as an actual specific for arthritis nor did he suggest that it precluded the necessity for careful elimination of all reflex sources of irritation, such as gastric and intestinal intoxications, the various sources of septic poisoning, uterine and general nervous derangements; but he could say that since using this method his results in the treatment of a considerable number of cases of this most intractable disease had shown remarkable and most gratifying improvement.—Dr. BUCKLEY said that he had given the methods under discussion a fair trial and had come to the conclusion that counter-irritation of the skin over the spine, whether by blisters or, as he preferred, by Paquelin's cautery, certainly alleviated pain; but he had found no evidence of any curative effect, nor did he think it likely that a disease which undoubtedly was due to bacterial action could be cured by such means.—Dr. A. MANTLE (Harrogate) said he did not favourably regard the treatment.—Dr. R. LLEWELYN JONES (Bath) spoke in support of the paper.—In his reply Mr. MIDELTON said that before submitting to the treatment by counter-irritation of the spine many of Dr. Champion's and his own patients had conscientiously tried every kind of treatment at home and abroad. Local disease was always looked for and treated if found.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Mammary Carcinoma.

A MEETING of this section was held on Nov. 27th, Mr. JOHN LENTAIGNE, the President, being in the chair.

Mr. EDWARD H. TAYLOR read a paper on Mammary Carcinoma and its Surgical Treatment. There was no region of the body, he thought, where so much had been learnt in recent years of the mode of the spread of cancer as in the breast, nor was there any region where more satisfactory results had been obtained by improved operative measures. What he had to say would have reference to the ordinary scirrhous form of the disease. Cancer first appeared as a small nodule in the breast, which gradually extended until it involved the whole of the breast and the adjacent tissues. There were also the lymphatic extensions, and the extensions which took place by the blood stream. For a long time the extension of cancer to lymphatic glands had been well known, and they instinctively examined for enlarged lymphatic glands in order to gain a correct idea of the extent of the case. The cancer might also extend along the lymphatic vessels in a way which had been described by Mr. W. Sampson Handley of London, and to that gentleman he was indebted for the slides which he would show in illustration of the spread of cancer by the lymphatics.[1] [Slides showing the various methods of extension were exhibited.] As to the treatment of cancer, his experience was that the cases of breast cancer usually met with were not favourable for a complete operation. He regarded as a favourable case one in which the disease was confined to the breast and in which there was no evidence of disease of the skin or of enlarged glands. If they found enlarged glands in the axilla they might regard the case as a late one in which the disease had travelled far, and such were the majority of cases which came to the surgeon. Until they got cases in earlier stages they could not hope for ideal results in treatment. The delay was largely due to the fact that it was very difficult at an early period to say that the case was one of cancer and the signs that they relied upon were really late signs. Another cause of delay was that patients put off seeing the medical practitioner until the symptoms had assumed a serious aspect. They should never hesitate to make an exploration by an incision along the outer periphery of the breast, cutting out a wedge-shaped mass which included the suspected swelling. He did not recommend cutting into the tumour to see if it was cancer. It should be cut out altogether. If the disease had involved the skin, if it was adherent to the chest wall, if the glands of the axilla were extensively enlarged, and if the glands in the supra-clavicular region were enlarged also, he did not believe there was any prospect of a permanent cure by operative measures. [Slides were shown in illustration of the stages of the radical operation.] In the case of limited disease the wound could be closed by suture but in later stages a grafting or autoplastic operation might be necessary. The arm should always be left free so that the patient had a good range of mobility and could gradually ge to use it. A great improvement had occurred in the operative treatment of such cases. Some operators had given thei successes as 40 per cent. or more. He was afraid that h could not lay claim to such satisfactory results. He had ha recurrences in patients more than three years after operation. The knowledge of the extension of breast cancer had been a extremely valuable acquisition to surgeons, and in view o what Mr. Handley had so ably described they shoul impress people with the importance of seeing a medical ma at the earliest possible moment when any tumour appeare in the breast. If they were to get good results in the futur he thought that it would not be by any further extension o the operation but by early and correct diagnosis.

Mr. WILLIAM TAYLOR emphasised the difficulty of diagnosis and recommended strongly that the general practitioner and the gynæcologist, who saw the case earlier tha the surgeon, should be impressed with the fact that at leas five out of six women with a lump in the breast were suffering from cancer. The earlier the age the more active wa the growth in the breast. Recurrence had been found up t 12 years after operation.

Mr. K. E. L. G. GUNN said that his own practice was t remove more skin than Mr. Taylor thought necessary. H only removed the greater pectoral if he could not clean th axilla without its removal.

The PRESIDENT said that they should strive to impress o educational authorities that it was more important for a gi to understand her health than to understand algebra, and one of the lessons a girl ought to be taught was the absolute necessity of attending at once to a lump that appears in the breast, or anywhere else. The danger was that uric acid is poisonous."[3] Other writers support the microbic origin of gout, whilst Sir Lauder Brunton is inclined to agree with Luff, "that the poison of gout might not be uric acid, but probably it was a substance allied to uric acid and probably a derivative of purin."[4] The only evidence of the bacterial theory of gout is that adequate clearage of the intestinal contents diminishes the gouty symptoms.

---

[1] THE LANCET, April 8th (p. 909), 15th (p. 983), and 22nd (p. 1047), 5.

Nor must we forget the all-important part played by the liver in the "metabolic commerce," as Sir Lauder Brunton so aptly puts it. Little or no consideration is at present paid by many people to the transformations which uric acid undergoes in the body, although these are quite as well marked as those of sugar, and affected to a great extent by the same organ—viz., the liver.

Whether uric acid is or is not toxic in itself is to my mind rather beside the question. What we know is that the presence of free uric acid in the blood is synchronous with an attack of gout, so much so that the uric acid and the gouty state have been considered synonymous terms. Now it is by no means necessary to assume that it is the cause of gout any more than that sugar in the urine is the cause of diabetes. Both point to a disturbance of metabolism and our treatment must be symptomatic until the true etiology has been discovered. The fact that uric acid is free means that the blood is abnormal and we know that the slightest variation from the normal may work for ill in manifold ways. Perhaps the phagocytes or antibodies are unable to work in this altered medium against the toxins which are the probable starting cause.

Important as it is to endeavour to find the actual cause of gout and to place our patients under those conditions best calculated to ward off a continuance of the attacks, it is more within the scope of this article to give some indications of treatment when the transformation of uric acid has actually occurred and deposition has taken place in the system. There is little doubt that the old-fashioned attack of gout endured by our forefathers is rarer nowadays. I think this may be explained by the fact that we live more carefully and take more exercise. Beer and heavy wines have given place to spirits, mineral waters, and the lighter wines. Meals, though perhaps more varied, are not so heavy. We now eat lighter dishes and more of them. But are we of this generation the gainers? Though our ancestors had their gouty attacks, they generally lived to a good old age. It is a serious question whether our business worries and the struggle for existence, our habits of late hours, whisky drinking, and excessive smoking, are not taking their toll in heart, liver, kidney, and nerve troubles, leading to defective metabolism and the production of the toxins and ferments they bring in their train. The gouty state of to-day is undoubtedly different from the gout of fifty years ago; less acute, but more insidious, more lasting, and more serious in its ultimate result upon health and strength. We have present in the blood a substance which lacks the requisite quantity of thyminic acid to be rendered inert. Having, therefore, discovered and removed, to the best of our ability, any possible cause, we must endeavour to relieve its mischievous effects by limiting its further production and preventing its deposition as a salt in the tissues.

The hygienic, dietetic, and therapeutic considerations in the prevention and treatment of gout should be carefully studied in every case. It is as irrational to feed every patient on nuts and vegetables as on underdone meat and port wine. "What is one man's meat is another man's poison" is an old adage that is remarkably true in the dietetic treatment of gout. The broad lines to work upon are a sufficiency of simple, wholesome, and well-cooked foods of mixed character (avoiding in acute cases the exhibition of those containing an excess of purins), efficient mastication, ample time for meals, and the avoidance during the same of the ingestion of soups and large potations. The amount of sugar and starch should be reduced to a minimum. It ought also to be remembered that salt, which so readily yields up its sodium, should be very sparingly taken. The question of a suitable beverage and its amount is a subject which exercises the mind of every patient one sees. It is quite impossible to draw a hard-and-fast line for every case. Alcohol in any form acts as a poison to some and it may certainly be quite advisable to order it to others. Some patients will not endure the total abstinence from what they look upon as a creature comfort, and in such cases fall back upon our judgment as to what is least harmful. The patient's own observations as to what kind of wine suits him is usually to be relied upon, but the quantity is another matter. "A glass or two" of port or champagne may mean anything up to a bottle, and I am convinced that spirits, wine, or malt liquors taken in any other than small quantities are as guilty as, if not more so than, food in producing evil in the digestive organs. I place spirits first advisedly, because, in my opinion, the profession has supported and maintained the extraordinary fetish of the "whisky and soda" of the present day. It is quite time the public were educated to the fact that a raw spirit, the flavour of which comes from the sherry cask, diluted with mineral water, is far from being a harmless beverage. It can do no good and often does an infinitude of harm. It has certainly done much to destroy the taste of the British public for pure light wines, as the majority of these now sold in England to suit the vitiated palate of the people are pasteurised or loaded, and are badly borne by the gouty. Perfectly pure and sound clarets and moselles are cheap and easily procurable, and little or no harm results from their consumption. An abundance of plain non-irritating fluid during the day is very advisable, and the natural waters of Vichy, Godes Berger, or Contrexéville are excellent. I have been particularly pleased with the results obtained by ordering a pint of skimmed milk in the early morning and the same amount at breakfast. It must be borne in mind that probably better results might follow the exhibition of butter-milk curdled by and containing growths of lactic acid bacteria.[5] Caffeine, the active principle of coffee and tea, is closely allied to uric acid in their organic equivalents (uric acid $C_5H_4N_4O_3$, caffeine $C_5HN_4O_2$) and should be avoided or sparingly consumed. Regular exercise, not spasmodic bursts of activity, is essential. I have often seen an attack of gout, sciatica, or lumbago following a day's hard hunting, when the heart and muscles are not tuned up to endure the strain. The business man living a sedentary, worrying life all the week ends up on Saturday and Sunday with three or four rounds of golf, and a painful elbow or shoulder lasting many weeks is the result. It is next to useless to advise our patients in these days to avoid mental worry and disquietude, and I have been particularly struck with the number of cases that have come to me where business worry is the sole predisposing cause.

The palliative remedies in vogue for the treatment of gout are many and varied. They may be classed under four heads: (1) the so-called uric acid solvents; (2) alteratives; (3) salicylates or their derivatives; and (4) alkalies.

1. During the past ten years a variety of so-called uric acid solvents have come within our reach—salts of lithia, phosphate of sodium, piperazine, pyridine, lysidine, lycetol, citarin, guaiacolate of piperidin, urotropine, uricedin, and urosin. Their action is the supposititious one of rendering soluble the biurate of sodium within the body, but in the absence of any proof that such solution is produced one must remain a sceptic as to their having any action in the elimination of uric acid or its derivatives. I am convinced that to depend upon the so-called uric acid solvent is to lean upon a broken reed. They play no possible part in holding uric acid in solution or preventing the formation of the biurate of sodium. Many irritate the mucous lining of the stomach and intestines and nearly all are depressing in their action.

2. Under the heading of alteratives we have the drugs colchicum, guaiacum, arsenic, and iodide of potassium, each valuable in its own sphere but with no reason for the results, good or bad, that sometimes follow their use. Colchicum has an undoubted action in checking the symptoms of acute gout, especially after the exhibition of a smart mercurial purge. But in the insidious and in the more subacute forms this drug is worse than useless, is a cardiac depressant, and is often badly borne.

3. Another group are the salicylic acid derivatives, salicylate of sodium, aspirin, &c., which undoubtedly possess valuable properties in the rheumatoid form of gout. In many forms the salicylic acid derivatives, especially aspirin, salol, and salicylate of sodium, have a marked beneficial effect, and Sir Lauder Brunton has pointed out the very valuable combination of salicylate of sodium and bromide of potassium in the

[5] Brit. Med. Jour., Sept. 19th, p. 847.

Sclerosis.—Mr. H. Lett showed: 1. A case of Osteitis Deformans. The patient was a man, aged 54 years. For six or seven years he had had pains in the tibiæ and he had had to wear caps as his head became too large for his hat. Both tibiæ were affected, as also the femora and right humerus. The characteristic curving of the lower extremities was well marked and there was kyphosis in the upper dorsal region. 2. A case of Atrophy of the Testis following an acute attack of Torsion of the Cord in a man, aged 21 years. The testis was very small and hard, and just above it a smaller lump representing the epididymis could be felt. 3. A case of Tertiary Syphilitic Periostitis of the Fibula in a woman, aged 57 years.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 17th, Dr. T. J. Wood being in the chair.—Mr. F. W. Goyder showed some pathological specimens.—Dr. F. W. Eurich gave a microscopical demonstration.—Dr. W. Mitchell in the course of some remarks on Ionic Medication gave an interesting demonstration of this method of introducing various drugs into the tissues. He thought that this method of treatment was being neglected by the general practitioner and pointed out how simple it was and what good results could be obtained by it.—Mr. James Phillips read a paper entitled "The First Three Weeks of Pregnancy and the Practical Bearing of Recent Investigations on our Knowledge of Ectopic Gestation." He quoted the recent work, from Peters's publication in 1899 to Bryce and Teacher's monograph published in October, 1908, done on the implantation of the ovum, showing that the fertilised ovum when it reached the uterus burrowed into the substance of the decidua and by setting up a coagulation necrosis opened up capillaries and thus established the maternal fœtal circulation. When the ovum was arrested within the Fallopian tube the same burrowing process and production of a necrotic zone round the ovum took place, accounting for the almost invariable termination of these cases by rupture. "The ovum in making its bed digs its own grave." Statistics were quoted showing that rupture into the lumen of the Fallopian tube and the formation of a tubal mole was a much more frequent event than intraperitoneal rupture and the importance of always thinking of tubal pregnancy in every case of sudden pelvic pain was emphasised.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Dec. 2nd, Dr. A. T. Wilkinson, the President, being in the chair.—Dr. W. Milligan made a communication upon Direct Laryngoscopy, Tracheoscopy, Bronchoscopy, and Œsophagoscopy. After a brief historical *résumé* of the history of laryngoscopy he demonstrated Kirstein's method of autoscopy and pointed out its advantages in the examination of young children and in obtaining a good view of the posterior laryngeal wall. Killian's instruments were shown and reference was made to the very valuable work done in his clinic. Brüning's electroscope, telescopic tubes, and extension forceps were also shown, the demonstration being aided by numerous lantern slides and stereoscopic photographs. The position of the patient, the question of anæsthesia, and the position and duties of assistants were mentioned. The value of direct laryngoscopy as a method of diagnosis and of treatment was then discussed, illustrative cases being quoted. Tracheoscopy and bronchoscopy, superior and inferior, were referred to and various useful instruments were shown. The history of œsophagoscopy was briefly touched upon and its value in the diagnosis of many obscure lesions of the food passage was insisted upon. The following cases were demonstrated: (1) Laryngeal Fibroma; (2) a patient operated upon for Laryngeal Fibro-papilloma; (3) Laryngeal Stenosis (Syphilitic); (4) Laryngeal Lupus; (5) Hysterical Spasm of the Œsophagus; and (6) Œsophageal Ulcer (Traumatic).

HOW DISEASE IS SPREAD.—A striking instance of how disease is spread was reported at the last meeting of the Shaftesbury (Dorset) rural district council by the medical officer of health (Mr. T. F. Hanly) who stated that he had been notified of a child suffering from diphtheria at the village of Huntingford. The case subsequently proved fatal. Mr. Hanly on visiting the house of the patient found that the father was at his usual occupation of milking cows.

Reviews and Notices of Books.

Oxford Medical Publications. Selections from the Writings, Medical and Neurological, of Sir WILLIAM BROADBENT, Bart., K.C.V.O. Edited by WALTER BROADBENT, M.D. Cantab., M.R.C.P. Lond. London: Henry Frowde and Hodder and Stoughton. 1908. Pp. 444. Price 15s. net.

WHEN the medical history of the latter part of the nineteenth century comes to be written there can be little doubt that the work of the late Sir William Broadbent will occupy a high place in the roll of honour. A minute and accurate observer, a man of rare and varied experience, and of wide outlook, he was a great physician and one who has left a large impress, not only on the students who came under his personal influence, but also upon the medical thought and progress of his time. Fortunately, his teaching has been preserved in the many lectures, contributions, brochures, and books which he produced, the list of the titles of which occupies nearly nine pages of this book before us. By collecting together into one volume some of the more important and characteristic of his lectures and publications his son, Dr. Walter Broadbent, has laid the profession under a debt of gratitude and has produced a worthy monument to his father's memory.

The various papers are on widely diverse subjects and were published at different periods of Sir William Broadbent's career. Some, as the editor informs us, are included in the present volume for their historical interest, others for the valuable information which they afford to the medical man of to-day, but in any case there is not one that we would have done without. The most striking feature of these writings considered as a whole is the thoroughly sound and practical common-sense which permeates them, illumined not infrequently by flashes of real inspiration. Not one of the least of the charms of these various papers is the clear and simple explanations given of many common symptoms and physical signs. In many of them some special case or series of cases is used as the text upon which to hang a general account of some disease or rare condition, and the accounts of these cases are invariably given in such language as to bring vividly before us the symptoms and physical signs, while the way in which they are utilised show that Sir William Broadbent was not only an extraordinarily acute observer but also a master in diagnosis. In regard to treatment, the book teems with practical hints and it can be read with great profit as a stimulating and instructive exercise by all who appreciate the value of exact and careful clinical observation of cases.

The first paper given in this volume is the last completed paper published shortly before the death of the author on the Examination of the Heart. It consists of a critical examination of the significance and value of the individual symptoms and physical signs observed in the various forms of cardiac disease. This paper is of interest, since it summarises the general principles applied by Sir William Broadbent in the diagnosis of cardiac lesions, a subject which he made so peculiarly his own and did so much to advance by his personal investigations. A number of the other papers are also devoted to consideration of cardio-vascular disease—such, for example, as those on the Conduct of the Heart in the face of Difficulties, on Adherent Pericardium, on Angina Pectoris and Pseudo-angina, on the Clinical Significance and Therapeutical Indications of Variations in the Blood Pressure, and on Aneurysm of the Aorta, all of which abound in useful practical suggestions.

An interesting paper on Venesection, reprinted from Vol. I. of THE LANCET of 1883, is strikingly up to date in its *résumé* of the practical application of that useful therapeutic measure me *to inject him for lumbago*, and here again the result was most satisfactory. I have given it with equally good results in four other cases, three of sciatica and one of neuritis of the ulnar nerve. In none of these did any unpleasant results follow except the usual numbing pain, quickly passing off, which follows any intra-muscular injection other than cocaine or morphine. Taking into consideration the chemical affinity of thyminic acid it is legitimate to assume that its local action would greatly lessen the deposition of the biurate of sodium upon the inflamed tissue or joint. I have since had sterilised tubes prepared by Messrs. Allen and Hanburys, *containing* two grains of thyminic acid and one-quarter grain of novocain, and find that the addition of the latter greatly mitigates the after pain of the injection. It is, of course, premature with so few cases to dogmatise upon its favourable action in this form, but it is natural to feel somewhat sanguine that its extended use may be equally successful. If this be the case a very valuable means of local treatment for these distressing symptoms will be within our reach.

Turning to the clinical results of the treatment of the gouty state by thyminic acid, I am convinced that we possess a very valuable and powerful agent, especially in the prevention of recurrent attacks of acute gout and in the cure or amelioration of the more chronic forms, and of those many ailments that we know now are marked by the excessive formation of uric acid within the system. It is in the prevention of attacks of acute gout, in the obesity so often allied with the gouty state, in gouty eczema, asthma, glycosuria, and stomachic derangements that thyminic acid attains its maximum of usefulness. A small dose (4 grains) taken daily after meals for a prolonged period, say of three months, and then every alternate week, will in most cases entirely *avert the onset of acute symptoms*, and I have a record of many patients who for the past three or four years have entirely escaped attacks that were formerly of constant occurrence.

When an acute attack of arthritic gout is actually in evidence I must confess that the action of thyminic acid has not been invariably successful, and I *prescribe mercurials* and a few doses of colchicum or colchicine with aspirin; then as the symptoms defervesce I order somewhat large doses of thyminic acid in conjunction with local treatment by the ray light bath, and the pain and swelling quickly subside.

Many of my patients who have broken their sequence of gouty attacks and have become free from even minor symptoms have discovered the efficacy of a few four-grain tablets of thyminic acid in obviating the evil effects of occasional indulgence in the pleasures of the table, for many people suffer acutely the day following a lapse from the prescribed regimen. Even a glass or two of champagne or port or alcohol of any kind will often cause great discomfort. Although I deprecate these lapses, yet it is consoling to note that a means to avert evil consequences is at hand. It is a decided proof of the efficacy of the drug that it renders inert any excess of uric acid which in some peculiar way alcohol in any form often produces. I have often been asked how many grains ought to be taken to obviate the ill-effects of some gargantuan banquet to which my *patient has been* invited. This question is as impossible to answer as it is sadly subversive of dietetic discipline.

During the past five years I have kept a careful record of the gouty cases that I have treated with thyminic acid. In my preceding remarks I have made it clear that the most striking results have been obtained in those who suffer from the more subacute and chronic varieties, whether connected with joints, tendons, muscles, skin, or nerves. The greatest benefit has also *accrued to that very large class* of cases where the apparent trouble is of gastric, hepatic, or intestinal origin. In obesity, which so often accompanies and is often the only symptom of the gouty state, the results are most gratifying. A gradual reduction of weight occurs without loss of strength. Nor need the patient be starved or nauseated by incongruous foods. In acute cases where we have to deal with an inflamed joint and accompanying pyrexia it is as well to combine the thyminic acid with colchicum or aspirin until the acute stage is passed. The days or weeks of intense depression, irritability, and want of energy so often observed are shortened by its continued administration and a recurrence of the attack averted.

In my former paper I gave a *description of some* cases I had up to that time treated with thyminic acid. Since then the treatment has been equally successful and many professional men have communicated to me the excellent results obtained by them. It would be a heavy task to give details of every case and invidious to select a few. I append an *analysis of cases taken at random* which I have divided into (1) acute and (2) subacute.

I.—*Cases of Acute Gout.*

CASE 1.—A man, aged 62 years. Previous history: Had repeated attacks of acute gout in the feet and knees up to five years ago when he began to take thyminic acid; was free from symptoms until last autumn, four weeks after returning from a course at Aix-les-Bains. Present attack (Oct. 2nd, 1908): *Began suddenly in left* great toe and spread rapidly along sheaths of tendons and involved knee; three days afterwards the right toe also was swollen and tender. Treatment: 8 grains thyminic acid every *four hours*; ray light bath *to* feet. Colchicine was also given for 48 hours. Remarks: There was rapid improvement; in nine days the attacks had passed off. He did not "take a course" this year and has been free since.

CASE 2.—A man, aged 59 years. Previous history: A parkkeeper; had always *enjoyed good health. Present attack (July 20th, 1908):* Acute sciatica had developed in right leg 14 days before; had tried the usual remedies; quite incapacitated for work. Treatment: Two intra-*muscular injections of thyminic acid followed* by 24 grains in tablets daily. Remarks: Relieved after first injection; cured after second. Has been well since.

CASE 3.—A man, aged 33 years. Previous history: Has had four attacks of acute gout, three in the feet, one in the right knee; usually incapacitated for three weeks. Present attack (May 9th, 1907): Typical attack [illegible] llen; very painful. Treatment: 8 grains [illegible] hours, with colchicine the first 24 hours; [illegible] knee. Remarks: The swelling and pain quickly [illegible] ppeared by the ninth day. Regularly takes thyminic acid and has been well since.

CASE 4.—A man, aged 44 years. Previous history: Had never previously had an acute attack but had several subacute attacks of lumbago and *gastric* catarrh. Present attack (April, 1907): Acute pharyngitis with glossitis; pyrexia. Treatment: 8 grains thyminic acid every four hours with colchisal. Remarks: Relief quickly followed and he was well on the fourth day. He has since taken 4 grains thyminic acid three times a day and has enjoyed good health.

CASE 5.—A man, aged 43 years. *Previous history*: Has passed large quantities of *"gravel" for some* years and has had repeated attacks of acute gout. Present attack (Feb. 10th, 1908): Acute arthritic attack of right ankle and joints of the foot and toes. Treatment: 8 grains thyminic acid every four hours; ray light bath locally; occasional doses of colchicine. Thyminic acid was continued in 8-grain doses. Remarks: The acute symptoms subsided in five days, the foot remaining swollen for three weeks. The "gravel" continually reappears but lessens or disappears entirely when the thyminic acid is resumed.

CASE 6.—A man, aged 43 years. Previous history: Has had several previous attacks. Present attack (October, 1907): Acute attack in right toe with gouty inflammation of the foot tendons and the tendo Achillis. Treatment: Thyminic acid and colchicine and ray light baths. Remarks: The inflammatory symptoms rapidly subsided; well on fifth day. Continued taking thyminic acid and has been well since.

II.—*Cases of Subacute Gout.*

CASE 1.—A man, aged 50 years. Previous history: Had previously had sciatica and various *minor symptoms* of the gouty state; careless as regards diet and alcohol; tophi and enlarged finger joints. Present attack (Feb. 8th, 1908): *Neuritis of the shoulder, arm,* and hand; loss *of* power; pain and wasting of muscles. Treatment: Thyminic acid in 8 grain doses; high-frequency electricity. Remarks: The symptoms gradually improved and in three weeks a complete cure had resulted. Thyminic acid continued for three months; has been well since.

CASE 2.—A man, aged 47 years. Previous history: Had previously had herpes zoster preputialis. Present attack (May 8th, 1908): Neuritis, shoulder to elbow, lasting three weeks. Treatment: Intramuscular injections of thyminic acid = 2 grains. Remarks: Two were given with complete success.

CASE 3.—A man, aged 46 years. *Previous history:* A "*gouty*" subject; a sufferer from "acquired gout." Present attack: Lumbago lasting 14 days. Treatment: *Intramuscular injections* of thyminic acid = 2 grains. Remarks: Two injections gave permanent relief.

CASE 4.—A man, aged 60 years. Previous history: A sufferer from *acquired gout of 10 years' duration, generally attacking* feet and legs; glycosuria; albuminuria. Treatment: Has taken thyminic acid with intervals for two and a half years. Remarks: Is now quite free from symptoms; glycosuria quite disappeared; small trace of albumin. Can walk and take exercise freely.

CASE 5.—A man, aged 42 years. Previous history: *A somewhat* careless liver, probably inherited gout; obese; height, 5 feet 9 inches. Present attack: Sept. 15th, 1907; weight, 16 stones 12 pounds. May 5th, 1908; weight, 13 stones 7 pounds. Treatment: Thyminic acid ordered in doses of 8 grains thrice daily. Remarks: Continues well in health; hunts regularly.

CASE 6.—A man, aged 62 years. *Previous history:* Had been a martyr to gout; at Droitwich, where he was "taking a course" in the winter, was laid up with an acute attack in the knees and ankles; confined to his bed for three months. Present attack (March, 1903): Pains and stiffness in the knees and ankles; quite unable to walk. Treatment: Thyminic acid in 8 grain doses with high-frequency electricity and ray light *baths. Remarks: In three weeks* could walk with comfort and is now able to shoot and play golf.

CASE 7.—A man, aged 50 years. Previous history: Has had several attacks of sciatica and a gouty knee with neuritis. Present attack: Has been quite free since taking thyminic acid 4 grains thrice daily. Can walk with comfort and play golf.

CASE 8.—A woman, aged 75 years. Previous history: Has suffered with inherited gout for many years; enlarged joints of fingers; unable to walk; recurrent attacks of acute eczema. Present attack: Has taken thyminic acid in doses of 4 grains for two years with very marked relief. Can now walk with comfort and has had no eczema for 18 months.

CASE 9.—A man, aged 40 years. Previous history: Acquired gout suffers with gouty neurasthenia attacks every three to four week sleeplessness, instability, anorexia; becomes quite unmanageabl in children from every point of view, prophylaxis and treatment naturally occupying the most important positions.

As there are so many contributions to this volume it is only possible for us to allude to a few, though most of the articles are interesting and instructive. Dr. J. S. Fowler (Edinburgh) writes on the Milk Problem and Tuberculosis in Infancy and Childhood. He is of opinion that tuberculous milk "is responsible for a quarter, more or less," of the tuberculosis of childhood. This estimate is probably too low but he very properly urges that stringent measures are demanded for the proper prevention of infection. He considers these measures under three headings: (1) legislative; (2) commercial; and (3) domestic. He maintains that the defect of existing legislation is that it is so largely optional, and we agree with him when he says that its adoption ought to be universal and compulsory. He recommends that all milk given to children should be sterilised by boiling and criticises the objections which have been raised against this procedure. He insists that but few children suffer in any way from taking sterilised milk and that the advantages far outweigh the disadvantages.

Eight chapters are occupied in the consideration of tuberculosis among children in different countries. Particularly interesting are the remarks by Professor R. Calmette (Lille) on the methods which are adopted in France for the prevention and cure of tuberculosis in children. There are in that country two classes of sanatoriums which have the above aims: the one deals with cases of pulmonary tuberculosis and the other is concerned with tuberculosis of bones, joints, and glands. The first class consists commonly of woodland sanatoriums; the other class is represented by seaside sanatoriums. Of the latter kind 24 are scattered along the English Channel, the Atlantic seaboard, and the Mediterranean coast, these stations having amongst them 3923 beds. The seaside treatment is pursued with the best results.

Amongst other articles in this book may be mentioned the following: Bovine Tuberculosis in Children, by Dr. Nathan Raw; Intrathoracic Tuberculosis in Infants and Children, by Dr. R. A. Young; Alpine Climates for Tuberculous and Tuberculously Disposed Children, by Dr. W. R. Huggard; and the Hygiene of the Nursery in Relation to Tuberculosis, by Mrs. M. A. D. Scharlieb, M.D., M.S.

Dr. Kelynack may be congratulated on having edited a work containing a large amount of information which can only be found scattered through many books, journals, or proceedings of scientific societies. The volume is of moderate size and the various contributions are essentially of a practical nature, mere theory having been eliminated.

LIBRARY TABLE.

The Lament of the Sweated. By JAMES SAMUELSON, of the Middle Temple, Barrister-at-Law. London: P. S. King and Son. 1908. Pp. 68. Price 1*s.* net.—In these pages Mr. Samuelson discusses the report of the 1907 Select Committee on Home Work. We deal with the same report in a leading article and need say little more except that those who are concerned at a terrible social evil but have not opportunity to gain knowledge of it at first hand will find in this little book a straightforward and sympathetic statement of the chief questions involved, together with a summary of the Committee's recommendations and of the measures which other countries have adopted to prevent the sweating of home workers. Mr. Samuelson's chief contribution is his advocacy of sanitary communal workrooms and crèches, to be erected by municipal or private benevolence. His book deserves a wide circle of readers but should it run into a second edition we hope that he will see his way to delete or to modify greatly his first chapter on "Dives." The fashion-page description of elaborate ball-dresses with which he seeks to "pile on the agony" of the contrast between the idle rich and the starving poor may well lose him the attention at the outset of many who take up the book. We must add that the author of its prefatory verses, who has tried to follow in the footsteps of Tom Hood, has stumbled into an unfortunate bathos as the reward of his rashness.

Legal Responsibility of the Drunkard. By H. NORMAN BARNETT, F.R.C.S. Edin., Surgeon, Cripples' Home, Belfast. With an Introduction by Sir ANDREW REED, K.C.B., C.V.O., Barrister-at-Law, late Inspector-General of Royal Irish Constabulary. London: Baillière, Tindall, and Cox. 1908. Pp. 64. Price 2*s.* 6*d.* net.—In this little treatise Mr. Barnett maintains that the civil and criminal actions of the chronic drunkard are not sufficiently recognised in courts of law as those of persons not of sound mind. He observes in his preface that "there is a growing feeling in legal circles that the drunkard should not be treated in quite the same way as another criminal. Recent medical research has clearly proved that this feeling is well founded." The pages which follow, however, contain a summary, not without interest, of the medical aspects of alcoholism but no very precise suggestion as to how these are to be established with a view to diminishing the criminal liability of the drunkard and to depriving him of his civil rights. We agree with the proposition that the medical rather than the legal profession must diagnose between the curable and incurable criminal; but we should also observe, with reference to the "legal circles" referred to above, that only a very small section of the legal profession, consisting of by no means its most influential members, is interested to any great extent in crime and criminals, and that in civil as well as criminal matters the jury which weighs the conflicting evidence of medical and other witnesses when mental soundness or unsoundness is the question at issue, is composed of persons without medical or legal training. Mr. Barnett in his concluding words suggests, unconsciously perhaps, at least one practical difficulty for which he hardly seems to propose a remedy. After explaining signs by which the chronic drunkard may be recognised he tells us that if we have one or more of these present with corroboratory evidence of a drinking habit, "*we* may conclude *whatever evidence may be produced to the contrary* [the italics are ours] that we are dealing with a drunkard suffering from mental degeneration and not fully responsible for his actions nor capable of using his full rights as a citizen." It is the "evidence to the contrary" and the fact that it is weighed not by experts but by a judge and jury which render unsatisfactory the status of persons mentally degenerate from other causes as well as from chronic alcoholism.

Who's Who, 1909. Pp. 2112. Price 10*s.* net. *Who's Who Year Book, 1909.* Pp. 154. Price 1*s.* net. *The Writers' and Artists' Year Book, 1909.* Pp. 118. Price 1*s.* net. *The Englishwoman's Year Book, 1909.* Pp. 372. Price 2*s.* 6*d.* net. London: Adam and Charles Black.—These four useful year books have made their appearance in good time for the coming year. The first and most important of them—namely, "Who's Who," has increased in size from 2040 to 2112 pages. The book's scope is too well known to need description and it would be as hopeless a task to review it as it would to review the "Peerage," but we may add that it would be a much more interesting task. For although a certain number of quite unimportant persons are bound to find their way by active or passive pushing into so comprehensive a manual, taken as a whole it is a really admirable catalogue of those who hold authority in every walk of life by right of brain-power and executive ability, as well as of those who were born in high observer. Another symptom common to this and some forms of middle-ear disease should here be mentioned—viz., the well-known phenomenon of hearing better in a noise, the theories as to the cause of which do not here concern us. Such results (other pathological conditions of the conducting apparatus being excluded) point to the more or less impaired mobility of the footplate of the stapes in the oval window in the immediate vicinity of which, as already stated, is the most common site for the disease.

Many cases, however, are found which do not conform to these results, the cause for which is probably dependent on the coexistence of other foci of the disease in the bony capsule of the labyrinth. Thus, for instance, the upper tone limit may be markedly shortened as well as the lower owing to the disease implicating the basal turn of the cochlea, a condition of affairs that one would really expect to find more frequently when the proximity of this structure to the margins of the oval window is remembered. Again, the disease may commence, though rarely, in other parts of the bony capsule, leaving the immediate neighbourhood of the oval window free, when the upper tone limit may be curtailed whilst the lower remains unaltered. In such cases the bone conduction may not be lengthened and may even be actually shortened, when a differential diagnosis will have to be made between otosclerosis and other affections of the auditory nerve.

Thus as regards the diagnosis we have three main classes to consider—the uncomplicated cases, those associated with other diseases of the middle ear and Eustachian tube, and those which have to be differentiated from other lesions of the auditory nerve itself. In early uncomplicated cases we have little else to depend on for diagnosis but the results of accurate functional tests and the absence of obstructive or catarrhal lesions in the tubes and middle ear—should in addition the membrane present a pinkish haze this is almost pathognomonic of the disease: In cases associated with catarrhal and post-inflammatory conditions in these situations the very slight improvement or even deterioration of the hearing after their treatment is very strongly suggestive of otosclerosis. When the disease involves portions of the bony capsule other than the margins of the oval window and the mobility of the stapedio-vestibular joint is unimpaired it is impossible at once to distinguish the symptoms to which it gives rise from those due to other diseases of the internal ear. The subsequent involvement of the conductive apparatus will, however, help to establish the diagnosis. In well-established uncomplicated cases of otosclerosis the diagnosis is generally quite straightforward.

Some observers have made use of a large series of tuning-forks in working out the functional tests in order to locate the site and to estimate the distribution of the disease in the bony capsule of the labyrinth. However, except perhaps from an academic point of view, such extensive data effect no object, whilst sufficiently accurate knowledge can be obtained with the use of three tuning-forks, "C^4," "C 64," and "E," together with testing the hearing with a standard watch, an acoumeter, or Galton's whistle. Mention ought also to be made of Gellé's test, the response to which, if positive, is very strong evidence against the presence of otosclerosis—at any rate in its most usual situation—because it points to mobility of the stapedio-vestibular joint and the functional integrity of the same.

Treatment.—As already stated, it is inconceivable, in the present state of our knowledge, that any local treatment can effect a cure or even permanent improvement in a disease of this nature, and such indeed is the conclusion to which one is driven after a careful review of the work done and of the efforts made in this direction. Many ingenious operations have been suggested and carried out, but although isolated instances are reported where temporary improvement has occurred, relapse and eventually further deterioration seem to be the usual result. Most operators freely admit the inefficacy and inadvisability of such attempts at operative interference. Removal of the stapes would at first sight seem reasonable as a possible means of removing the cause of obstruction in the region of the oval window, and with this end in view that operation has been performed. Small trephine openings have also been made into the vestibule through the inner wall of the tympanum with the object of allowing an unimpeded transmission of sound waves to the termination of the auditory nerve. Neither of these procedures, however, has been followed by any appreciable success, but indeed more often they have led to increased deafness. This is not surprising when we reflect that the resulting cicatrices must, if anything, constitute a lesion more obstructive to the passage of sound waves than the pre-existing bony barrier. Finally, various attempts have been made towards the remobilisation of the stapedio-vestibular joint, but they have served only to stimulate a firmer ankylosis of that articulation. Injections of fluids and vapours *viâ* the Eustachian tube have been practised *ad nauseam*, but, as such a statement indicates, with no beneficial effects. Rapidly recurring variations of air pressure in the external auditory meatus, by which some claim to have obtained improvement, have for their object a remobilisation of the joints of the ossicular chain, and in particular of the stapedio-vestibular joint.

Theoretically it seems most improbable that any such oto-massage can influence the process of disease in the latter situation even in its earlier stages, and when ankylosis has occurred, a beneficial effect from this procedure appears inconceivable. Practically, too, the results are most disappointing. In watching these cases in a large clinic I have been unable to find any patients who were really improved by this form of treatment. Indeed, more often than not, any local procedures, even repeated politzerisations, will only aggravate the deafness, the associated tinnitus, and general discomfort.

Attempts at local treatment are therefore strictly contra-indicated, and in uncomplicated cases all manipulative or operative procedures in the nose and naso-pharynx should be studiously avoided. Indeed, even as regards treatment of other parts of the body, when a choice is offered, the least drastic measures should be adopted, since as above stated, mental stress or physical strain tends to aggravate the symptoms. We have thus to rely on such general treatment as is available. This resolves itself into an effort to relieve the symptoms and, if possible, prevent the further progress of the local lesions.

Although the deafness would seem to be the greater calamity, these patients are often very much more worried by the tinnitus, so much so that it is not uncommon for them to say that they would not mind the former disability if only the latter could be arrested. Unfortunately, severe tinnitus points to extensive involvement of the bony capsule of the labyrinth and makes the outlook both as regards progress and relief the more unfavourable.

In the first place, an outline of the nature of the complaint should be given to the patients so that they may realise the position of affairs and thus be saved repeated and unproductive consultations. They should then be advised to put themselves under the care of their usual medical attendant for a course of treatment extending over several months with the object of so improving their general condition that a further unfavourable progress may be prevented. Such treatment should consist in a very strict adherence to the general rules of health coupled with the exhibition of such medicinal aids as will conduce to the maintenance of all the functions of the body in the best possible state. The efficient and healthy action of the alimentary tract and digestive apparatus must be insured, and any other concurrent maladies, such as anæmia and its results, should be treated, and special attention should also be paid to sufficient exercise, fresh air, judicious clothing, and diet, whilst that climate or locality which best suits the patient's general health should be strongly advised. Avoidance of worry and overwork, in so far as it may be possible, should be also enjoined, as they doubtless act unfavourably on the course of the disease.

Since in some cases every successive confinement appears to have a prejudicial influence on the symptoms limitation of children has been recommended. Although it is probable that pregnancy and the puerperium, like other heavy demands on the system, have a causal relation to the incidence and progress of the disease, the advisability of this suggestion is open to many objections. It is quite conceivable that to deny a patient the satisfaction of her maternal instincts may after all do much more harm than if matters are allowed to take their natural course. It is, however, most important to insist on the necessity of a thoroughly able anæsthetist and skilled accoucheur whose efforts will combine to reduce shock and hæmorrhage to the lowest possible minimum.

For the acute exacerbations of the symptoms, which from time to time occur during the course of the disease, some relief may be gained by the application of blisters to the of Dr. A. R. Neligan's Notes on Persia which are written with the authority of a legation physician, and a paper on Big Game Shooting by Dr. Percy Rendall who proves himself no less a *shikhari* than a naturalist. Mr. Herbert W. Page's long experience of railway litigation makes his contribution to the *St. Mary's Hospital Gazette* (November) a valuable one, dealing as it does with Functional Disease *versus* Organic Disease Following Accidents. The leading contribution to the *St. Thomas's Hospital Gazette* (November) is an interesting paper by Dr. T. D. Acland on Egypt and the Soudan. The information which he gives concerning the medical education and clinical work done under the British occupation of Egypt affords an ample justification for that measure.

# Reports and Analytical Records
FROM
THE LANCET LABORATORY.

(1) TABLETS FOR THE ESTIMATION OF SUGAR IN URINE; AND (2) TABLETS FOR THE ESTIMATION OF ALBUMIN.

(E. MERCK, DARMSTADT, LONDON OFFICE, 16, JEWRY-STREET, E.C.)

1. THE estimation of sugar in urine is made extremely simple and nevertheless accurate by means of these reagent tablets. Tablet A contains the copper salt and tablet B the necessary amount of alkali. The reducing value of two tablets dissolved in water is equal to 0·01 gramme of glucose, so that should the urine to be tested contain 1 per cent. of sugar 1 cubic centimetre suffices to reduce completely the copper contained in tablet A. The analytical method of procedure is simple. One copper and one alkali tablet are dissolved in 2·5 cubic centimetres of water and to this, after heating to boiling, 2·0 cubic centimetres of urine are added and the mixture is boiled. It is then filtered through a good filter and should the filtrate be yellow or brown the urine contains more than 0·5 per cent. of sugar. If the filtrate should be green or blue then less than this amount is indicated. The test is repeated, less or more urine being used until the exact quantity is found to reduce the copper completely in the tablet. In the case of a urine containing a large percentage of sugar it is desirable to dilute the urine to a definite volume before proceeding to the analysis. We found the method to be exact when operating on standard solutions of glucose containing 0·5 per cent. and 0·2 per cent. respectively of sugar. 2. The tablets for the detection of albumin in urine also answered satisfactorily. Of these we received three kinds—namely, Esbach's reagent, Riegler's reagent (beta-naphthalene sulphonic acid), and a test called A and B, in which two different tablets are employed containing citric acid and potassium ferrocyanide respectively. The advantage of Riegler's reagent is that while it precipitates albumin, albumose, and peptone, the last two disappear on boiling. The Esbach reagent can be used for the determination of albumin by measuring the volume of the precipitate in an Esmarch tube.

TOOTH SOAPS AND POWDER.

(EDWARD COOK AND CO., LIMITED, SOAP WORKS, BOW, LONDON, E)

These preparations present certain novelties and are designed to meet the cult of the aseptic mouth. "Biscuit," for instance, is a pleasantly scented soap tablet of chocolate colour which is most useful for the cleansing and washing of dental plates. According to our examination, it contains a fine impalpable powder which serves as a burnisher, besides which are present an antiseptic and, of course, a detergent. It is very agreeable to use and answers its purpose satisfactorily. "Hygeso," according to our analysis, contains an antacid in addition to the soap which is the basis and a deodorant. Like the last preparation it is very pleasant to use and leaves a sense of cleanly condition in the mouth. Lastly, "Royalist" is a powder containing a well-known antiseptic absorbed in fine chalk. It is free from sharp gritty particles.

SCOTCH WHISKY.

(JOHN SOMERVILLE AND CO., LIMITED, CRAIGMILLAR, EDINBURGH.)

This whisky is guaranteed to be ten years old and we can well believe the statement, judging from the flavour of the spirit which is mild and mellow. It is, in fact, very soft and smooth to the palate, the absence of raw and acrid constituents thus being indicated. Furthermore, the results of the analysis implied the genuineness of the spirit in regard to its origin, that is to say, from malt. The results of analyses were as follows: alcohol, by volume 48·75 per cent.; extractives, 0·12 per cent.; and mineral matter, 0·02 per cent. Amongst the secondary products were ethers 77 parts and furfural 3 parts per 100,000 parts of alcohol present. In view of this analysis we believe this whisky to be genuinely described, and it is therefore suitable, when permitted, for dietetic requirements.

LEGUMINE BISCUITS (VOEBT).

(WILCOX, JOZEAU, AND CO., 49, HAYMARKET, LONDON, S W)

One important novelty in regard to these biscuits is that they are made with legumine, or vegetable albumin, and another interesting feature about them is that the starch has been partially converted into dextrin by means of diastase. The biscuits, therefore, should be easily digestible. Our analysis gave the following results: moisture, 9·20 per cent.; mineral matter, 11·70 per cent.; protein, 13·59 per cent.; and carbohydrate, 65·51 per cent. The biscuits seem well adapted for weak digestions, as in cases of persons suffering from dyspepsia or other gastric troubles. Further, they contain a very decided proportion of phosphorus in an organic form—that is to say, as glycero-phosphate. They have also been suggested for use in diabetes but owing to the carbohydrates present they should not be used for this purpose except under the supervision of a medical man in order that a watch may be kept over the tolerance of the patient in regard to a diet containing substances easily converted into sugar.

MAGI MINERAL WATER.

(CALEDONIA SPRINGS CO., LIMITED, 133, JERMYN STREET, ST. JAMES'S, LONDON, S.W.)

This water, bottled at the springs at Caledonia, Ontario, Canada, shows an interesting composition. The springs are situated midway between Montreal and Ottawa and are under the control and supervision of the Canadian and Pacific Railway Company. The water is somewhat highly mineralised, the chief salt present being sodium chloride, which, according to our analysis, amounts to 479·000 grains per gallon out of a total amount of salts of 513·000 grains per gallon. The water is also alkaline, due to the presence of carbonates of the alkalies and alkaline earths. It further contains a notable quantity of the bromides and iodides of sodium. The water clearly belongs to the class known as alkaline carbonated, and saline, which have been used in the treatment of gastric and intestinal catarrh, rheumatism, and gout. According to the analysis of Professor A. S. Eve of McGill University the water is decidedly radio-active. The water is somewhat saline to the taste but is pleasantly sparkling.

VI-TONICA.

(SLACK AND COX, HYDE ROAD, MANCHESTER)

It is quite justifiable to call Vi-Tonica a temperance beverage since, according to our analysis, there is no appreciable amount of alcohol present. The extractives amounted to 8·72 per cent. which consist chiefly of sugar. Quinine and phosphates were readily found, the employment should be very small, just visible to the naked eye, otherwise the too abundant vapour of the metalloid will mask the reaction completely. Take care also in heating the copper wire not to heat the top of the tube, or the mercurial vapour, not being able to sublime on the warm glass, will escape into the cotton-wool plug. To obtain a still more delicate reaction gold in grains should be used instead of copper, proceeding in identically the same way as described.

From the study of what I have observed with Dr. Fortuna I formulate the following conclusions. 1. The mercurial reaction in the urine of the healthy is much more evident than in the syphilitic, in which sometimes there is no result at all; which means that the elimination of mercury in the urine of the syphilitic is always much slower than in the healthy. 2. The mercurial reaction is *nil*, or nearly so, in cases of syphilis recently contracted, especially when symptoms are apparent; and the reaction is only slightly evident, and never so well as in normal cases, in the syphilitics in whom two or three years have elapsed since the appearance of the ulcer. 3. Finally, in cases of long standing, of, say, 10 or 12 years, the mercurial reaction is as evident as in normal cases. (*Mercurial reaction is positive.*)

Now, to come to the consideration of the matter in order to explain these facts we must be content with a hypothesis. In the first place, in the subject of syphilis, the mercury introduced perhaps unites itself in a special organic combination with the virus, for which, being a specific remedy, it must have a special affinity, and in this condition it does not pass, or passes only with difficulty, the renal filter, and at the same time does not have any offensive action on the organism. Thus in this fashion it would be easy to understand the old empiric advice to wait before commencing the general cure until the secondary symptoms have appeared and remain in view for some time. Lesser, who had occasion to analyse the phenomena from this point of view, had the conviction that the morbid evolution is milder and more regular if the general treatment is commenced rather later and not before the secondary symptoms.

From what I have observed myself in my patients I participate in the opinion of Lesser and firmly believe that a too early treatment is unadvisable, because the action of the antigen being paralysed by the mercury the production is stopped of the special antibodies which would be the natural defence of the organism provided for the true destruction of the virus. When the virus is already in subjection to the specific antibodies (in old syphilis), or is absent, or the mercury has been given in excess, the mercury passes freely through in the urine.

On the other hand, the rapid elimination in the pseudo-syphilitic is probably due to a vital tendency of the organism to expel whatever is noxious to it. For whatever concerns the intolerance to mercury observed in the pseudo-syphilitic, at least in the beginning of the treatment, I believe it lasts only until the specific antibodies of the mercurial antigen have not come to paralyse its poisonous action. It is Boeri, one of the first in his fine work on the immunity against non-bacterial poisons, who has experimentally demonstrated this new form of immunity acquired by the organism, and here to put in parenthesis it must be remembered what Salmon said about the therapy: "That sometimes in the course of the therapy of syphilis one sees a first treatment followed by a rapid improvement, and a second, third, and fourth series of cures to become less and less beneficial, and it is convenient for this to alternate the mercury with atoxyl and *vice versâ*." I personally believe that it is most probable that the antitoxic reaction which proceeds in the organism against these special poisons neutralises their therapeutic action.

The scientific work of late years on the sero-diagnosis of syphilis has given good results. Thus Wassermann's reaction has especially met with the favour of the bacteriologists and of the clinicians. "It is more frequently both positive when the disease is flourishing in every period, including that of primitive ulcer; it is particularly intense in the secondary manifestations, and it may also be intensely positive in hereditary syphilis; it may also be positive in latent forms, but in this condition the percentage of negative results is larger" (Micheli Borelli); but Wassermann's reaction is not at hand for all practitioners who are not trained to this kind of research.

On the contrary, the mercurial reaction as here described is absolutely simple in technique. It may render good service not only in doubtful cases of syphilis and in obscure exanthema but also in retrospective diagnosis, as when one wants to know if an individual who presents no symptoms of acquired syphilis has been at some past time a victim of the infection. This, however, on condition that not too long has elapsed since the date of the suspected infection.

I have not yet had occasion to test the mercurial reaction in tabes or progressive paralysis not hereditary syphilis, but I anticipate that in the case of tabes and of paralysis it must give positive results, these diseases being almost certainly not of syphilitic nature but simply of syphilitic origin.

I am glad to announce to my colleagues for investigation these new observations on syphilis, and I hope that further research will confirm their usefulness.

Shaftesbury-avenue, W.C.

A CASE OF RUPTURED SMALL INTESTINE;

OPERATION; SUBSEQUENT TRANS-PLEURAL DRAINAGE OF TWO SUB-DIAPHRAGMATIC ABSCESSES; RECOVERY.

By LIONEL E. C. NORBURY, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR, ST. THOMAS'S HOSPITAL, LONDON, S.E.

THE patient, aged 28 years, was admitted to St. Thomas's Hospital on Oct. 15th, 1907, under the care of Mr. C. A. Ballance, with a history of having fallen some 30 to 40 feet from a crane which was being employed for unloading a barge—it could not be ascertained which portion of his body came in contact with the barge; a period of unconsciousness followed, but consciousness had returned on admission. The patient appeared pale and collapsed; general severe abdominal pain was complained of; the pulse-rate was 80 per minute, the respirations were 32, and the temperature was 97·4° F. No bruising of the abdominal wall was visible; the abdomen moved poorly on respiration. A localised area of dulness was detected in the left flank; no shifting dulness and no obliteration of liver dulness could be made out. The urine was withdrawn by catheter but it contained no blood. One and a half hours later the pulse-rate was 72 per minute, the area of dulness had increased in extent towards the splenic region, and the abdominal pain was still severe but there was no vomiting. Six hours later the pulse-rate had risen to 92, and at the end of nine hours it had reached 104 per minute. The area of dulness had increased and extended from just below the left costal margin as far as Poupart's ligament on its outer half and to some extent backwards into the loin; abdominal pain was still a marked feature. The temperature had gradually risen to 99·4°. There was no abdominal distension.

From these signs and symptoms a diagnosis of probable rupture of the intestine was made and an exploratory operation was undertaken some ten hours after the accident. The abdomen was opened by a four-inch vertical incision just to the left of the mid-line and having its centre opposite the umbilicus, the fibres of the rectus were separated, and on opening the peritoneum a moderate amount of thin turbid fluid was evacuated but no gas. A condition of acute peritonitis was present, the walls of the intestine being markedly injected and sticky lymph everywhere present, but chiefly so in the left half of the abdomen; there was no fæcal odour. The small intestine was rapidly passed in view and a rupture some one and a half inches in length was discovered in the long axis of the bowel and opposite its mesenteric attachment. This was closed by a double row of continuous silk sutures, the first taking up all the coats and the second only the sero-muscular coats. A small tear in the mesentery opposite the rupture was also sutured with silk. Bruising of adjacent coils of intestine and of the omentum was also present. The exact level of the lesion was not definitely ascertained, but it apparently involved the jejunum or upper portion of the ileum. A second smaller incision through the right rectus just above Poupart's ligament was next made, a drainage-tube was passed int
pelvis, and the peritoneal cavity was thoroughly
with normal saline solution. The abdominal wall wa
in layers, the pelvic cavity being drained by a tu
through the lower incision. Intravenous infusion w

THE LANCET.

LONDON: SATURDAY, DECEMBER 19, 1908.

Medicine and Imperial Expansion.

THE ominous unrest in our great Indian dependency gives a relevance all its own to the remark of one of the most sagacious of Viceroys, Lord LAWRENCE, who, on quitting his post, made the public declaration that "our Eastern Empire owes more to medico-missionaries like Dr. HUSBAND than to its regular officials." The distinguished physician whose career elicited this remark died on Nov. 21st at his post after 38 years of labour as unremitting as it was well-directed. Bearing an honoured name in the practical defence of Jennerian vaccination Dr. HUSBAND was commissioned by the United Presbyterian Church of Scotland to carry on the medical department of its Christianising work in 1870, and, chiefly in Ajmir, picturesquely situated in Central Rajputana, the highest tableland of Hindostan proper, he so exerted himself in behalf of the corporeal no less than the spiritual wants of the natives that he shared with his colleagues, Dr. J. SHEPHERD of Udaipur and Rev. J. SOMMERVILLE of Jodhpur, the title of "King" in his province. Having come to know the people "in their habit as they lived," their joys and sorrows, their predilections and their aspirations, he found a way to their minds and souls denied to all but the most sympathetically suasive of missionaries—conciliating not only their admiration and respect but their affection and devotion, till his popularity with all classes and creeds gained him the highest seat in the municipality—nay, even the *entrée* into their *vie intime*. Such confidence had they in his philanthropy and practical good sense that they courted his advice in their domestic affairs, in their business concerns, and in the education of their sons and daughters.

The late QUEEN and EMPRESS, on the occasion of her jubilee in 1897, acknowledged his services, civic as well as professional, by making him a Companion of the Most Eminent Order of the Indian Empire. His efforts for the advancement of every Hindoo interest knew no limits, and not only in the hospital and in the dispensary but in the hostel and the orphanage, in the workshop and in the printing office, he strove to extend and to enrich the army of breadwinners, content—nay, zealous—to fulfil their destiny as citizens and as loyal subjects of the British Crown. In exceptional visitations—those of famine, for example—he is credited with having saved thousands of lives. *O si sic omnes.* Such men are the true pioneers and consolidators of empire, justifying the noble eulogy pronounced on them by the Bishop of BIRMINGHAM at Edgbaston on the day of Dr. HUSBAND'S death, and giving cogency to his statement that "the India Office was profoundly convinced that unless we could get a basis for human brotherhood and common sympathy between Englishmen and the people of India, neither our Empire nor our civilisation could last."

The Bishop of Zanzibar, Dr. J. E. HINE, who is both an M.D. of London and a D.D. of the University of Oxford, had indeed anticipated his Right Reverend brother of Birmingham in the address with which he opened the Medical Missions section of the Pan-Anglican Congress last summer, emphasising as he did the primary importance of the care of the injured and the ailing in their private homes and in the hospital, and showing how the "loving care of the body" must always precede the instruction, secular or religious, of the evangelist. Even the nurse, he went on to say, "reached quarters which would otherwise be inaccessible." The practical corollary to be deduced from this and similar testimony is, as THE LANCET has time and again insisted upon, the promotion of medical study and research in our outlying "spheres of influence" by the institution of chairs of medicine, tropical and sub-tropical, such as have been endowed under the best auspices in more than one British school. The competition of rival colonising powers comes in as an incentive to such a movement—the French, for example, as was pointed out at the Pan-Anglican Congress, having done splendid work in the island of Madagascar, thanks to the provision which they have made for the medical training of their missionaries. The time will come when, instead of the medico-missionary work being left to one and the same individual, the two qualifications, that of physician and surgeon on the one hand and evangelist on the other, will be kept separate, to the greater efficiency of either functionary in his special sphere. Of this happy division of labour—unity in duality—the Bishop of ZANZIBAR gave most interesting illustration, still further driving home the conclusion that Great Britain's control of her dependencies and colonies will be effective and lasting in the degree in which she secures to the natives that care of the body, in health and disease, which must precede all subsequent effort towards their reclamation to civilised life and brotherly citizenship.

◆

Sweated Industries and Sanitation.

DURING the summer session a Select Committee of Parliamentary representatives of all shades of political opinion sat at Westminster to take evidence and to report upon the many issues, economic, hygienic, and humanitarian, which affect those engaged in industrial work in their own homes. The committee had before it Mr. RAMSAY MACDONALD'S Home Work Regulation Bill and was asked to consider Mr. ARTHUR HENDERSON'S Sweated Industries Bill which it has reported without amendment. The minutes of evidence issued with the committee's report on the general order of reference make gloomy reading when we consider that 65 of the most progressive years in the country's history have elapsed since the conscience of the nation was awakened to the degrading industrial slavery existing in its wealthiest cities by the publication of the "Song of the Shirt." Since that year legislation has done a great deal to promote the physical welfare of the working classes, especially of those who gain their living in workshops and factories and by dangerous trades, but the lot of the home worker—the most defenceless should be very small, just visible to the naked eye, otherwise the too abundant vapour of the metalloid will mask the reaction completely. Take care also in heating the copper wire not to heat the top of the tube, or the mercurial vapour, not being able to sublime on the warm glass, will escape into the cotton-wool plug. To obtain a still more delicate reaction gold in grains should be used instead of copper, proceeding in identically the same way as described.

From the study of what I have observed with Dr. Fortuna I formulate the following conclusions. 1. The mercurial reaction in the urine of the healthy is much more evident than in the syphilitic, in which sometimes there is no result at all; which means that the elimination of mercury in the urine of the syphilitic is always much slower than in the healthy. 2. The mercurial reaction is *nil*, or nearly so, in cases of syphilis recently contracted, especially when symptoms are apparent; and the reaction is only slightly evident, and never so well as in normal cases, in the syphilitics in whom two or three years have elapsed since the appearance of the ulcer. 3. Finally, in cases of long standing, of, say, 10 or 12 years, the mercurial reaction is as evident as in normal cases. (Mercurial reaction is positive.)

Now, to come to the consideration of the matter in order to explain these facts we must be content with a hypothesis. In the first place, in the subject of syphilis, the mercury introduced perhaps unites itself in a special organic combination with the virus, for which, being a specific remedy, it must have a special affinity, and in this condition it does not pass, or passes only with difficulty, the renal filter, and at the same time does not have any offensive action on the organism. Thus in this fashion it would be easy to understand the old empiric advice to wait before commencing the general cure until the secondary symptoms have appeared and remain in view for some time. Lesser, who had occasion to analyse the phenomena from this point of view, had the conviction that the morbid evolution is milder and more regular if the general treatment is commenced rather later and not before the secondary symptoms.

From what I have observed myself in my patients I participate in the opinion of Lesser and firmly believe that a too early treatment is unadvisable, because the action of the antigen being paralysed by the mercury the production is stopped of the special antibodies which would be the natural defence of the organism provided for the true destruction of the virus. When the virus is already in subjection to the specific antibodies (in old syphilis), or is absent, or the mercury has been given in excess, the mercury passes freely through in the urine.

On the other hand, the rapid elimination in the pseudo-syphilitic is probably due to a vital tendency of the organism to expel whatever is noxious to it. For whatever concerns the intolerance to mercury observed in the pseudo-syphilitic, at least in the beginning of the treatment, I believe it lasts only until the specific antibodies of the mercurial antigen have not come to paralyse its poisonous action. It is Boeri, one of the first in his fine work on the immunity against non-bacterial poisons, who has experimentally demonstrated this new form of immunity acquired by the organism, and here to put in parenthesis it must be remembered what Salmon said about the therapy: "That sometimes in the course of the therapy of syphilis one sees a first treatment followed by a rapid improvement, and a second, third, and fourth series of cures to become less and less beneficial, and it is convenient for this to alternate the mercury with atoxyl and *vice versâ*." I personally believe that it is most probable that the antitoxic reaction which proceeds in the organism against these special poisons neutralises their therapeutic action.

The scientific work of late years on the sero-diagnosis of syphilis has given good results. Thus Wassermann's reaction has especially met with the favour of the bacteriologists and of the clinicians. "It is more frequently both positive when the disease is flourishing in every period, including that of primitive ulcer; it is particularly intense in the secondary manifestations, and it may also be intensely positive in hereditary syphilis; it may also be positive in latent forms, but in this condition the percentage of negative results is larger" (Micheli Borelli); but Wassermann's reaction is not at hand for all practitioners who are not trained to this kind of research.

On the contrary, the mercurial reaction as here described is absolutely simple in technique. It may render good service not only in doubtful cases of syphilis and in obscure exanthema but also in retrospective diagnosis, as when one wants to know if an individual who presents no symptoms of acquired syphilis has been at some past time a victim of the infection. This, however, on condition that not too long has elapsed since the date of the suspected infection.

I have not yet had occasion to test the mercurial reaction in tabes or progressive paralysis not hereditary syphilis, but I anticipate that in the case of tabes and of paralysis it must give positive results, these diseases being almost certainly not of syphilitic nature but simply of syphilitic origin.

I am glad to announce to my colleagues for investigation these new observations on syphilis, and I hope that further research will confirm their usefulness.

Shaftesbury-avenue, W.C.

A CASE OF RUPTURED SMALL INTESTINE;

OPERATION; SUBSEQUENT TRANS-PLEURAL DRAINAGE OF TWO SUB-DIAPHRAGMATIC ABSCESSES; RECOVERY.

BY LIONEL E. C. NORBURY, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR, ST. THOMAS'S HOSPITAL, LONDON, S.E.

THE patient, aged 28 years, was admitted to St. Thomas's Hospital on Oct. 15th, 1907, under the care of Mr. C. A. Ballance, with a history of having fallen some 30 to 40 feet from a crane which was being employed for unloading a barge—it could not be ascertained which portion of his body came in contact with the barge; a period of unconsciousness followed, but consciousness had returned on admission. The patient appeared pale and collapsed; general severe abdominal pain was complained of; the pulse-rate was 80 per minute, the respirations were 32, and the temperature was 97·4° F. No bruising of the abdominal wall was visible; the abdomen moved poorly on respiration. A localised area of dulness was detected in the left flank; no shifting dulness and no obliteration of liver dulness could be made out. The urine was withdrawn by catheter but it contained no blood. One and a half hours later the pulse-rate was 72 per minute, the area of dulness had increased in extent towards the splenic region, and the abdominal pain was still severe but there was no vomiting. Six hours later the pulse-rate had risen to 92, and at the end of nine hours it had reached 104 per minute. The area of dulness had increased and extended from just below the left costal margin as far as Poupart's ligament on its outer half and to some extent backwards into the loin; abdominal pain was still a marked feature. The temperature had gradually risen to 99·4°. There was no abdominal distension.

From these signs and symptoms a diagnosis of probable rupture of the intestine was made and an exploratory operation was undertaken some ten hours after the accident. The abdomen was opened by a four-inch vertical incision just to the left of the mid-line and having its centre opposite the umbilicus, the fibres of the rectus were separated, and on opening the peritoneum a moderate amount of thin turbid fluid was evacuated but no gas. A condition of acute peritonitis was present, the walls of the intestine being markedly injected and sticky lymph everywhere present, but chiefly so in the left half of the abdomen; there was no fæcal odour. The small intestine was rapidly passed in view and a rupture some one and a half inches in length was discovered in the long axis of the bowel and opposite its mesenteric attachment. This was closed by a double row of continuous silk sutures, the first taking up all the coats and the second only the sero-muscular coats. A small tear in the mesentery opposite the rupture was also sutured with silk. Bruising of adjacent coils of intestine and of the omentum was also present. The exact level of the lesion was not definitely ascertained, but it apparently involved the jejunum or upper portion of the ileum. A second smaller incision through the right rectus just above Poupart's ligament was next made, a drainage-tube was passed into [illegible] pelvis, and the peritoneal cavity was thoroughly i[illegible] with normal saline solution. The abdominal wall [illegible] in layers, the pelvic cavity being drained by [illegible] through the lower incision. Intravenous infus[illegible] the work.'" A very important suggestion made by the committee is that the imposition by law of obligations upon owners of factories and workshops tends to encourage employers to resort to home work in order to avoid these obligations and the visits of inspectors. The committee's investigation of the existing law with regard to home work retells an old story, that local authorities do not make sufficient use of the imperfect sanitary powers which they possess already. These powers fall under the general public health law concerning dwellings and certain special provisions of the Factory and Workshop Act of 1901, the chief of which prohibits any person to give out work to be done in premises which are injurious to the health of the persons employed therein. Persons giving out work are obliged to supply twice a year to the local authority a list of the outworkers whom they employ. These lists are usually incomplete and incorrect. Other Acts, such as the Truck Act of 1896, made for the protection of workers' wages, are often frustrated in their application to home workers and the committee is satisfied that the existing law has failed to produce any amelioration in their condition and that legislation of a far-reaching character is required.

The report then summarises some of the laws existing in other countries for the protection of home workers and proceeds to make its recommendations which we must record with little comment. These include the following suggestions:—

(2.) That legislation should at first be tentative and experimental, and be limited in its scope to home workers engaged in the tailoring, shirtmaking, underclothing, and baby linen trades, and in the finishing processes of machine-made lace. The Home Secretary should be empowered after inquiry made, to establish Wages Boards for any other trades.

(3.) That Wages Boards representing both workers and employers should be established in selected trades to fix minimum time and piece rates of payment for home workers in those trades.

(4.) That it should be an offence to pay or offer lower rates of payment to home workers in those trades than the minimum rates which had been fixed for that district by the Wages Board.

(6.) That all home workers who are employed by other persons in producing or preparing articles for sale should be required to register their name, address, and class of work at, and receive a certificate of such registration from, the offices of the local authority, and that the keeping of accurate outworkers' lists by employers should be strictly enforced.

(7.) That it should be an offence for any person to employ any home worker to produce or prepare any articles for sale by another person unless the worker produce a certificate of registration.

(8.) That the provisions of Section 9 of the Public Health Act, 1875, with regard to factories and workshops which are not kept clean or are ill-ventilated or overcrowded should be extended to rooms in which home work is done, and power should be given to sanitary and factory inspectors to inspect them and secure the enforcement of the law.

(9.) That the full protection of the Truck Act should be secured to home workers.

Recommendation (6) was apparently the outcome of Dr. DUDFIELD'S evidence given in 1907, and together with (7) and (8) it will probably receive the support of many medical officers of health. It will be seen that no suggestion is made of abolishing home work by establishing communal workrooms and crèches, which will occur to many as a possible and radical method of reform and which is advocated in Mr. J. SAMUELSON'S little book "The Lament of the Sweated" which we review in another column. Although this may seem an ideal solution, the time is hardly ripe for it yet, but it is over-ripe for the extension to home workers of the sanitary advantages secured to factory and workshop hands. Advantages would accrue not only to the workers but to the purchasers of their produce, for the present system which allows of clothes and other articles intended for sale to be heaped up on the beds and tables of a den used for both eating and sleeping by the wretched toiler who calls it "home," must surely lead to the dissemination of disease when the goods are distributed to the public. On this point the committee might well have sought more direct evidence. It strengthens us in asking the Government to give the recommendations of the Select Committee on Home Work its early and thorough consideration. In the mean time health officers should urge by all means in their power on their local authorities the enforcement of such powers as the committee has reminded them that they possess. The trade interests involved in certain districts doubtless clash with the sanitary interests of the community in this as in many other matters, and it affords an additional argument for demanding that the security of tenure of medical officers of health should cease to be dependent on private interest and caprice.

◆

Medical Education in France.

WE have received the annual *Numéro des Etudiants et des Praticiens* published by the French weekly medical journal *Le Progrès Médical.* It is on the same general lines as the Students' Number of THE LANCET and it supplies a very interesting and complete summary of the educational facilities afforded to the student and the practitioner of medicine in France. In addition it supplies valuable information regarding the regulations for the various examinations in the different universities and general advice to the practitioner regarding the laws governing medical education and practice, and is in effect a very complete presentation of all that concerns the official aspect of the medical curriculum and the profession of medicine. It opens with an address to the student in which he is advised to avail himself of the courses of instruction provided by the Faculty of Medicine of his university, and to seek to acquire the habit of observation. The necessity for practical work is strongly emphasised and the student is enjoined to go to the hospital daily from the time that he commences the study of medicine, and to endeavour to form his own opinions in regard to cases. The importance of a due perspective in regard to his work is also most strongly insisted on.

The actual subject matter of this special number is divided into four parts, the first of which is devoted to a general account of the universities and schools of medicine and to the general arrangements for medical students and practitioners. There are 15 universities in France and one in Algiers, but only seven of these—viz., Bordeaux, Lille. Lyons, Montpellier, Nancy, Paris, and Toulouse—possess a Faculty of Medicine. There are, however, in addition 17 schools of medicine, divided into two classes—schools for the complete curriculum, comprising Marseilles, Nantes, Rennes, and Algiers, and preparatory schools at Amiens.

hysterectomy known as the Wertheim and the Krönig-Wertheim.

The study of the spread of cancer from the rectum has led me to formulate certain essentials in the technique of the operation which must be strictly adhered to if satisfactory results are to be obtained—namely: (1) that an abdominal anus is a necessity; (2) that the whole of the pelvic colon, with the exception of the part from which the colostomy is made, must be removed because its blood-supply is contained in the zone of upward spread; (3) that the whole of the pelvic mesocolon below the point where it crosses the common iliac artery, together with a strip of peritoneum at least an inch wide on either side of it, must be cleared away; (4) that the group of lymph nodes situated over the bifurcation of the common iliac artery are in all instances to be removed; and lastly (5), that the perineal portion of the operation should be carried out as widely as possible so that the lateral and downward zones of spread may be effectively extirpated.

The Operation.

This is one of the most formidable operations in surgery, entailing, as it does, the removal of practically the whole of the pelvic colon as well as the rectum. I have now performed it 12 times with a mortality of 41·6 per cent. Nine of the patients were males, of whom four died, and three were females, of whom one died. The surviving seven patients are all at present free from recurrence, the first three having been operated upon in January, March, and May of 1907 respectively.

Preparation of the patient.—In all cases in which there is marked stenosis of the bowel, a preliminary left iliac colostomy should be performed at least two weeks before the operation. If there be no abdominal distension and if the lumen of the bowel be not much encroached upon the colon should be thoroughly emptied of its contents by the aid of enemata and mild purgation.

Method of operating.—The patient having been placed in an exaggerated Trendelenburg posture, a median incision is made from the umbilicus to the symphysis pubis and a self-retaining abdominal claw retractor is placed in position. The pelvic colon is then drawn out into the wound and a left iliac colostomy, if one does not already exist, is established in the usual situation through a second incision. I usually do this by simply pushing a loop of the uppermost part of the pelvic colon through an incision in the abdominal wall and fixing it in position in the ordinary way. Some operators advocate first dividing the bowel and then establishing the colostomy from the proximal end only, but I think that by so doing there is a greater tendency to protrusion afterwards. As soon as the knuckle of colon has been fixed in position in the manner indicated, the pelvic colon is divided transversely about two inches below it and both ends are closed firmly by means of purse-string sutures. The closure of the distal end should be done carefully, so as to avoid leakage from that part of the bowel during the subsequent steps of the operation. The peritoneal covering of the pelvic mesocolon is then divided transversely backwards on either side to the point where the pelvic mesocolon crosses the common iliac artery, the incisions extending into the parietal peritoneum for the distance of about one inch. The inferior mesenteric artery is then ligatured below the point where it gives off its uppermost branch to the pelvic colon. When this has been done the pelvic mesocolon itself is divided completely as far backwards as its parietal attachment, the inferior mesenteric artery being divided below the point of ligature. The upper and remaining portion of the pelvic mesocolon is now turned upwards for the distance of an inch or more and all the cellular tissue containing the group of lymph nodes situated over the bifurcation of the left common iliac artery dissected carefully away. All bleeding vessels in the cut edge of the pelvic mesocolon are caught and tied. The remainder of the operation is now practically bloodless and should be rapidly proceeded with. The peritoneum is next divided by incisions which extend downwards into the pelvis, one on either side of the parietal attachment of the pelvic mesocolon and at least one inch distant from it, until the recto-vesical pouch is reached, when they are carried round the lateral aspects of the pelvic wall to meet again in front just behind the base of the bladder. In the female the left broad ligament should be detached, together with the left ovary and tube. This having been done, the pelvic mesocolon together with the adjacent strip of peritoneum on either side of it is detached from the hollow of the sacrum. By keeping close to the anterior sacral ligaments, the cellular tissue containing the lymph nodes in that situation is detached with the pelvic mesocolon in one piece. This separation is continued downwards in the middle line as far as the sacro-coccygeal articulation. A similar method of blunt dissection is then carried out anteriorly, by which means the bladder is detached as far as the prostate gland. Attention is now paid to the separation of the lateral aspects of the rectum and it is here that great care must be exercised to avoid injuring the left ureter, which adheres closely to the peritoneum as it skirts the wall of the pelvis. When the ureter has been defined it should be carefully freed as far as the base of the bladder. On the right side the ureter need not be seen. The dissection is then carried downwards on either side and the lateral ligaments of the rectum are divided with scissors. In these structures the middle hæmorrhoidal arteries are found but seldom require a ligature. This lateral dissection is carried down to the upper surface of the levatores ani. When the rectum has thus been freed on all sides as far as the points indicated, the whole of the detached structures are crowded down into the pelvis and covered with sterilised gauze. Provided that the divided end of the colon has been firmly closed considerable pressure may be made upon it from above without fear of leakage. The edges of the pelvic peritoneum are now sutured so as to re-establish the pelvic floor. This having been done, the pelvis is thoroughly flushed with saline solution and the abdominal wound closed. The patient is now turned over and placed in the right lateral and semi-prone position so that the perineal portion of the operation can be proceeded with. A purse-string suture having been inserted round the anus to prevent escape of its contents, a transverse incision is made at the level of the sacro-coccygeal joint and from the centre of this a median incision is carried down to within an inch of the anus. From the lowermost extremity of the latter a semicircular incision is made round the anus on either side, meeting anteriorly at the central point of the perineum. These last incisions should include as wide an area of skin as possible so as to insure excision of the zone of downward spread. After reflecting the skin on either side to the requisite extent, the coccyx is removed and the interval between the levatores ani defined. These muscles should be divided as far outwards as their origin from the "white line" so as to include the lateral zone of spread. The remainder of the fascia propria of the rectum is then detached from the lower part of the sacrum when the pelvic colon and the rectum, which lie loose in the hollow of the sacrum, can be drawn out of the wound. The lower part of the rectum is then dissected from the prostate or the vagina, as the case may be, care being taken to remove the cellular tissue in its vicinity as freely as possible. The resulting chasm is then freely irrigated with saline solution and all bleeding vessels are tied. Finally, the skin margins are brought together with sutures and a large drainage-tube is inserted in the anterior and the posterior extremities of the median incision. The patient is now turned upon his back and as the final step of the operation a small opening is made into the extruded bowel to allow of the escape of flatus.

The operation thus performed takes from an hour and a quarter to an hour and a half and, so far as my experience goes, the patient suffers from no more shock than after an ordinary perineal excision.

The mortality after the operation appears to be high, but it must be remembered that the disease for which it is performed claims a mortality of 100 per cent. if left alone and of over 90 per cent. from recurrence when operated upon by the perineal methods. The causes of death in my cases have been: one from hypostatic congestion of the lungs, one from strangulation of a knuckle of small intestine which had become herniated through a rent in the peritoneal pelvic floor, one from gangrene of the stump of the pelvic colon below the colostomy, and two from peritonitis. With the exception of the first named I regard all these causes of death as preventable with further experience of the operation and with improved technique, and therefore hope that in a future series of cases I shall be able to show a lower degree of mortality than 41·6 per cent.

Upper Wimpole street, W.

difficult of those many problems which confront us to-day. The solution of them, not only in this country but in every modern civilised country, lies at the very root of the modern industrial system. It involves questions of child labour, of the labour of parents, of the labour of women in mills and factories, of proper housing, and of provision of playgrounds. To solve the problems will require a system of national self-denial and of a real public spirit which at present seems to be absent. But the first step to the solution of any problem is the wish to solve it and it is cheering to find that the National League has at least got so far on its toilsome journey.

A LONDON WORTHY AND TALL BUILDINGS.

THE Clarendon Press has issued recently a reprint of "The Survey of London," made long ago by John Stow, the famous Tudor tailor. It forms an archæological document of exceptional interest to all who feel any curiosity concerning the development of the greatest city that the world has ever seen. Mr. Charles Whibley bases an article in the December number of the *National Review* on this fascinating volume and calls attention to Stow's great antipathy to tall buildings. He lived in an age when the timber houses which were destined to be swept away by the Great Fire were replacing many of the older stone buildings. This pleased Stow the more in that men were not tempted to rear their wooden structures high up into the air. Not only did he inveigh against the iniquity of those who built presumptuously, but he quoted two "awful examples" of the fate which would surely overtake them. Alderman Angell Dune, who set a high brick tower upon his house, was struck with blindness and unable to gaze upon his handiwork, and Richard Wethell was punished for the same offence by becoming "in short time so tormented with goutes in his joynts, of the handes and legges, that he could neither feed himself, nor goe further than he was led, much lesse was he able to climbe, and take the pleasures of the height of his Tower." The object of these lofty houses seems to have been a display of importance. At that period they were certainly not erected with the aggressive motive which inspired the architecture of so many mediæval Italian towns and which was, of course, the desire of every family of consequence to possess a vantage ground from which its members could shoot down upon their neighbours' houses in times of civil feud. Bologna and San Gimignano, to name only two towns, have many beautiful examples of such towers still standing. Neither can their motives have been those which have led to the erection of such "skyscrapers" as disfigure New York city of to-day. Although many Americans of æsthetic sense would perhaps gladly inspire the streets of their metropolis with something of the Tudor spirit, and share the pious assurance of John Stow that the sins of all modern children of Babel will be visited upon their bodies, there can be no doubt that the tall city building has come to stay. Modern economy of ground-space in cities and concentration of business interests make this fact apparent, and London street architecture is fast responding to its insistent commercial necessity. In a recent annotation we called attention to the fact that a man who lives at the top of a high building has the advantage of exceptionally pure air to breathe. But there are many interests to consider in a community and the blessing of the Londoner on the house-top is the bane of his brothers in the street. We cannot put the case in better language than in that of Mr. Whibley's article: "London is a true city of the North, and cannot endure tall houses, which shut out the light and cast long shadows. Nothing should interrupt the rays of the sun, always too few, which fall upon its streets. ...... (London's) citizens are free to heap up mountains of brick and mortar, of stone and iron. ...... in order that they may swell an over-full pocket, the poor wayfarer must walk up and down like a pigmy at the bottom of a sightless airless tank." He might almost have written of certain streets "a septic tank," for the living bacterial population of narrow thoroughfares which are never exposed to the antiseptic rays of the sun must be inconceivably great. We can only hope that the widening of streets will in some measure keep pace with the upward growth of the buildings which bound them, and that our building laws may forbid in perpetuity the appearance in any British town of such a skyline as appears to be inseparable from the great business centres of America. If a John Stow redivivus were to cross the Atlantic we fear that even the full-flavoured breadth of the Tudor vocabulary would fail to do justice to his emotions on approaching New York.

REGISTERED MEDICAL WOMEN AND THE POLITICAL FRANCHISE.

ON Nov. 2nd a committee of the Association of Registered Medical Women of the United Kingdom wrote to the Prime Minister asking for an opportunity of laying before him certain facts in favour of the extension of the political suffrage to women. The request was supported by the results of an inquiry which showed that of all the registered medical women resident in the United Kingdom 538 were in favour and 15 against the extension. The 16 signatories to this communication included Mrs. Garrett Anderson, M.D., Dr. Sophia Jex-Blake, Dr. Julia Cock, Dr. Jane H. Walker, Mrs. Mary Scharlieb, M.D., Mrs. Florence N. Boyd, M.D., and Dr. Louisa B. Aldrich-Blake. Mr. Asquith, in his reply, expressed his interest in the figures submitted to him and requested the association to make its representations in writing, as he regretted that pressure of public business would prevent him from receiving a deputation of medical women. On Dec. 10th the same ladies, with the addition of three others, forwarded a memorandum to Mr. Asquith in support of their claims. We are unable to print the document in full in this issue but summarise its arguments, which, we may mention, are expressed in studiously temperate language. The association claims that: 1. Legislation not infrequently deals with matters directly concerning medical practitioners, and the interests of all such practitioners should be protected by the vote. 2. Medical women are a tax-paying and self-supporting body and afford a striking example of taxation without representation, which is opposed to the first principles of English liberty. 3. Many medical women are graduates of a university and as such are entitled to the university franchise, a privilege from which they have been excluded by an arbitrary decision. 4. Members of the medical profession are called on to perform services of an arduous and responsible nature to their fellows and to give skilled advice to the State but receive no recognition of these services. The voteless position of women practitioners is especially anomalous, as they possess legal power to deprive men of their right to vote by signing certificates of insanity. 5. Work amongst all classes has given medical women an especial insight into the disabilities from which their sisters suffer through lack of political representation. The unhygienic conditions of poor women and children and the problems presented by criminal and intemperate women and by prostitution are closely associated with the economic conditions of female labour. 6. Women should have a direct voice in legislation upon these matters and also upon questions of education, religion, guardianship of children, housing of the poor, and all issues of public health and morals. 7. The possession of the vote would temperature; the relapses in these cases, however, were never so severe as the primary manifestations, 48 hours in bed again bringing the temperature to normal.

With regard to treatment, all these cases were isolated at once on rise of temperature, however slight, or on complaint of soreness of throat, and owing to this precaution in a colony of 160 people only 15 were affected with the malady. Formalin tablets were vapourised daily and freely in all dormitories and day rooms while the inmates were out of doors. Formamint lozenges were sucked (three a day) by all not affected, and by those affected a lozenge every three hours, while frequent swabbing of the tonsils and pharynx with "izal" solution (suitably diluted) was resorted to. All cups, spoons, &c., used by the affected inmates were sterilised in formalin solution after use. In addition to the swabbing, spraying of the pharynx and nares with the formalin spray was also carried out. I might mention that the place where this outbreak occurred is situated in a healthy part of the country 800 feet above sea level, where drainage and other sanitary arrangements are carried out on the most approved and modern lines. There are no poultry or cattle, &c., kept near the premises.

No sooner had this epidemic abated than one of a similar but more severe nature occurred in my practice here at a private preparatory school, consisting of 40 pupils with staff of masters, head master's family, servants, &c., numbering upwards of 60 people in all. The building is healthily situated, 400 feet above sea level, in the country, and remote from any other dwelling. The sanitation of the whole building had just been completed at a cost of £200, with drainage into a "septic tank" some distance from the building. A few fowls, horses, pigs, cows, &c., are kept near the premises, but there is allowed no offensive accumulation of excreta from these sources. The analysis of drinking-water was satisfactory. The pupils live an out-of-door life as much as possible and practically at this time of the year (May and June) are only indoors at lessons, meals, and to sleep. The building is constructed with the view to the admittance of as much light and fresh air as possible; all windows open widely and are kept open as much as existing conditions of weather permit. There was a history, before the commencement of the epidemic, of one boy returning to school who had had sore throat which had imperfectly cleared up. In from two to three weeks later a boy was seized with convulsions. I saw him soon after the abatement of the seizure. His temperature was 103° F.; he complained of no sore throat, but his cervical glands were enlarged and tender. He was isolated at once. On seeing him next day he had a creamy secretion over both tonsils but not extending on to the palate, uvula, or faucial pillars. There was much angry congestion over the latter, and he now complained of much difficulty and pain on swallowing.

Four other boys on this day were put to bed with rise of temperature, tenderness over the cervical glands, headache, malaise, and some pain on swallowing on one or both sides. One of these showed much more cervical glandular enlargement and had a more suspicious look about his fauces and tonsils than the rest. Moreover, he had signs of much nasal obstruction and he was isolated. A swab from his throat showed Klebs-Löffler bacilli. He was treated with 4000 units of antitoxin, swabbed with izal, sucked formamint lozenges, and the usual treatment was carried out by both night and day nurses. He proved to be a severe case of diphtheria of the fauces and nares, with marked heart and kidney trouble, and succumbed 14 days after onset of symptoms to cardiac failure.

Swabs from other throats showed Hofmann's diplococci and streptococci but no diphtheria bacilli. Boys fell down like ninepins, whole classes going sick one by one, all with similar symptoms and local signs. One boy, and only one, had middle-ear trouble ending in suppuration, with no mastoid complication. Repeated swabs were taken for examination. The specific bacillus was only found in one other case of the 30 affected, and in this boy local throat signs were slight, but he was isolated and had no ill after-effects; in fact, his malady was of so slight an importance to him that he never really complained of feeling ill. He had no abnormal gland swelling and no nose trouble. A feature of this epidemic and one that was so very striking that the veriest tyro on throat affections could not have failed to notice it, was the comparative slightness of the internal (tonsillar and pharyngeal) signs in the older boys of from 12 to 14 years of age, with in some cases no secretion or exudation, and the mildness of their constitutional symptoms; while the younger boys of from 10 to 12 years of age had sharp febrile disturbance, with much pain in the throat and glands and took much longer time to convalesce, whilst the subsequent anæmia was often very marked. Some showed signs of heart dilatation, some had none. Most had tenderness with swelling of the glands at the angle of the jaw and around the sterno-mastoid. In some cases slight, in others very marked, glandular enlargement was noticeable, taking many weeks to subside to the normal. Some, again, had albuminuria, mostly of a very transient nature, only lasting from three to four days. Some had none, and in no non-diphtheritic case was there a true nephritis or endocarditis. One boy in whom a tonsillotomy had been done a year or so previously acquired the disease and had a very sharp attack. Several of the cases developed dilated hearts with apex beat well out in the mid-axillary line. This complication, however, cleared up with prolonged rest. Appetite was good, almost ravenous, even though much secretion and faucial swelling were present; headache was persistent in a few cases, little or absent in most. There was no doubt about the izal swabbings and sucking of formamint doing good in checking the amount of secretion and local pain on swallowing. Several cases had to return to bed after getting up in the dormitory for a short time after the temperature had been normal for several days and secretion had disappeared. This was in most cases due to a secondary adenitis in the cervical glands, even in those who had had previously but slight gland trouble, yet the relapse was often more severe than the primary adenitis and much more obstinate in clearing up. No case went on to suppuration. In several the pharyngeal tonsil and adjacent lymphoid tissue showed signs of congestion for from two to three weeks after disappearance of throat discomfort and the nares were in a few cases slow to resume their normal appearances. Some made rapid strides in convalescence, others remained anæmic for from three to four weeks, and in one case, after the boy had been sent home and had been resting in open air for three weeks after the attack, news was received of his having to take to bed again with rise of temperature and return of his former gland symptoms.

This all points to the persistence of the infection even after a period of apparent normal health; the streptococcus, no doubt, can linger on in the remote parts of the fauces, nares, Eustachian tubes, and query in the cervical glands even after all symptoms of the affection are past and done with. Hæmatogen and maltine with iron ("bynophosphates") seemed to do most good as an after tonic, and the incidence of warm sunshine in the latter part of June seemed to put a check to the spread of the infection. A notable feature of the epidemic was a slight pharyngitis experienced by the adult people (masters and servants) of the school with no serious constitutional disturbance; this was not fanciful but real, as I had an opportunity of examining the fauces of those affected.

My reasons for reporting these two epidemics are, firstly, the now well-understood possibility of a "diphtheritic" supervening on or accompanying a "diphtheroid" infection; and, secondly, of a streptococcal infection (with staphylococcal) going hand-in-hand with both and gaining sometimes the upper hand, and so minimising the risks run had the former reigned alone supreme, and that none the less is a streptococcal throat infection to be treated lightly, owing to the persistent and clinging properties of the micro-organism resulting in much adenitis and subsequent constitutional disturbance and anæmia.

I had almost hoped for a case of scarlet fever to crop up during the course of this epidemic to add further evidence to the well-known "possibilities" of micro-organisms of the streptococcal group. My expectations were ultimately realised, for in a family of six children residing in an isolated country cottage five developed streptococcal throats, all females, while the sixth child, a boy, aged six years, developed true scarlet fever in a very typical form: he desquamated freely and in eight weeks had finished peeling and was in good health. From the three epidemics, then, described above, in three separate households, streptococci were found to be present in the throat swabs in all three instances, and the possible and various results of streptococcal infection were well illustrated in the production of a tonsillitis, an erysipelas, and scarlet fever.

Knowle, Warwickshire.

excess of the general mortality; this occurs at all ages and is most marked in Saxony at almost every age, is less marked in the Gotha experience, but only occurs after age 40 in Würtemberg.

MORTALITY OF MEDICAL MEN COMPARED TO NORMAL (= 100).

Ages.	Gotha insured.	Saxony.	Wurtemberg.
26 to 45	125·9	124·6	92·4
46 „ 65	109·6	128·9	117·8
26 „ 65	114·1	127·5	107·8

There is but little difference between the mortality of town and country practitioners, the place of residence having much less influence than the conditions of the profession. Westergaard found the same fact in his investigations among Danish medical men. Karup and Gollmer consider the excessive mortality to be due to professional risks—e.g., exposure to typhoid fever, unfavourable conditions of weather and temperature, and the incessant activity of the profession. Looking at the mortality from individual causes, practising physicians show the excess chiefly in respiratory diseases (including pulmonary tuberculosis), in apoplexy, and in typhoid fever. The mortality from tubercle is 106·7 per cent. of the expected mortality, that from infectious diseases no less than 131 per cent. Among minor points brought out are the two following:—Radestock's continuation of Geissler's Saxon investigations indicates a slight rise in the expectation of life for medical men; the Gotha figures show that the mortality of medical lecturers in the universities closely resembles that of medical men generally."

MILTON'S BLINDNESS.

John Milton is generally supposed to have suffered from amaurosis, of which the old name was *gutta serena*. In the great autobiographical opening to Book III. of "Paradise Lost" the blind poet, apostrophising Light, plays on the Latin name in well-known lines:

> "Thee I revisit safe,
> And feel thy sov'reign vital lamp; but thou
> Revisit'st not these eyes, that roll in vain
> To find thy piercing ray, and find no dawn;
> So thick a drop serene hath quench'd their orbs,
> Or dim suffusion veil'd."

According to others, among whom was his late biographer, Leslie Stephen, Milton's complete loss of eyesight was due to glaucoma. To judge from the passage above quoted, the poet himself was not entirely convinced of the nature of his disease, though he gloried in the fact that he had incurred it in the service of his country. The lines seem to express alternative etiologies. The darkness fell upon him soon after his completion of the "Defensio Populi Anglicani" in 1654. "Paradise Lost," therefore, was the *magnum opus* of a blind man. Now, though such an affliction as complete loss of the use of a sense might be supposed to militate against the highest kind of achievement in art, it is a question whether in Milton's case such loss did not enhance his performance. According to Jonathan Richardson, who wrote when Miltonic tradition was still quite fresh, the poet dictated his poem in snatches between 1658 and 1662—ten lines to a chance caller, 20 lines to his daughter Anne whom he would wake up in his grim paternal fashion to act as his amanuensis during the hours of a sleepless night. According to a tradition traced to the third Mrs. Milton the poet dictated his poem, in batches of some 300 lines at a time, after rising in the early morning. These batches were composed during night vigils. Whichever tradition we accept, the fact remains that Milton's great epic was recited and dictated; it was the work of a *trouvère* of supreme genius; it owed nothing in the first instance to the restraining influences of the pen. Hence the Miltonic harmonies, the stresses, cæsuras, crowded syllables, pauses, which lend the poem its peculiar majesty and charm. Blindness for once may be said to have been beneficent when we consider the manner in which "Paradise Lost" was composed. Milton's insomnia deserves a word in passing. He was a man with memories when he began the composition of his poem at the age of 50 years, and these with his gout and his active mind may well have kept him awake or awakened him in the small hours. But his regimen was a starveling one, his dinner often consisting of olives. And he went to bed at nine like a man of great age.

ANIMATED PHOTOGRAPHY IN NATURAL COLOURS.

ON Wednesday evening, Dec. 9th, there was a crowded meeting at the Royal Society of Arts, London, to hear an interesting lecture given by Mr. G. Albert Smith, F.R.A.S., on Kinematography in Natural Colours. Sir J. C. Lamb, C.B., C.M.G., presided. In THE LANCET of May 9th last (p. 1358) we recorded a demonstration of Mr. Smith's invention which was given at Urbanora House, London, under the auspices of Mr. Charles Urban, F.Z.S., who has greatly assisted Mr. Smith in his endeavours. Mr. Smith now showed what progress he had made in the interval and his results when thrown upon the screen were received with much applause. Mr. Smith explained in outline the three-colour theory and said that six years ago when Mr. Urban invited him to take part with him in a series of experiments to obtain animated photography in colours it was upon that principle that the experiments were undertaken, but a difficulty was found in superimposing the three colour pictures as they could not be made to "register" accurately, and it was decided to try to make them superimpose in the mind of the observer by running the film through the machine very fast. This was an improvement but the colours were extremely pale, in fact, washy. Mr. Smith then set to work to make a film sensitive to all colours, especially red, and to reduce the records necessary from three to two, because in using three colours they cannot be replaced quickly enough to obtain the superimposition. It was necessary also to devise a scheme which could be readily adapted to all existing kinematographs and bioscopes and to the ordinary standard film of the usual perforation. Eventually Mr. Smith succeeded in making a sensitised film which when exposed with the use of small rotating transparent coloured screens inserted in front of or behind the lens of the camera filtered the light and recorded, in a scale of greys ranging from white to black, on one film, the corresponding range of colour. This record is a record of colour sensation as the spiral on the phonograph cylinder is a record of sound waves. In Mr. Smith's words, "the colour is there in black and white." White represents white, yellow is represented by a slight tinge of grey, and for the other colours the records get darker and darker till they get down to black. From these films or colour records the original colours are reproduced on the screen (sheet) by the optical lantern with the interposition of the rotating coloured disc, as described in THE LANCET of May 9th. This range of colours Mr. Smith has been able to represent in two records by having in the camera a revolving shutter with scarlet and blue-green portions alternately arranged. Through the scarlet shutter he records white, yellow, orange, and reds. Through the blue-green shutter he records white, yellow (again), green, and a little blue. Only a little blue is required, as too much blue is mischievous and gives very pale colours. These pictures are taken at the rate of 32 per second and they must be taken in the bright sunshine. This rate is twice that necessary for the ordinary black and white films. Mr. Smith reminded his audience that very great always combined with twice the amount of sodium bicarbonate. The initial dose for an adult should be 150 grains daily, with a daily increase of 20 to 50 grains until the temperature fell and remained normal. Unpleasant symptoms should be followed by a temporary reduction of the dose, and when these disappeared the drug should again be cautiously increased. Sodium salicylate was not a cardiac depressant. Two precautions were necessary: to give sufficient bicarbonate of sodium to render the urine alkaline and to prevent constipation. Under this treatment the dilatation of the left ventricle rapidly disappeared. In rheumatic pericarditis and myocarditis the application of an icebag was of great assistance. If there was evidence of dilatation of the right auricle this must be relieved by leeches before the ice was applied.

The PRESIDENT, Mr. W. J. MIDELTON, Dr. F. J. POYNTON, Dr. W. H. WILLCOX, Dr. J. GRAY DUNCANSON, Dr. H. C. CAMERON, and Professor W. E. DIXON joined in the discussion which followed.

MEDICAL SOCIETY OF LONDON.

Athletics in Relation to Disease.

A MEETING of this society was held on Dec. 14th, Mr. C. B. LOCKWOOD, the President, being in the chair.

Mr. R. H. A. WHITELOCKE (Oxford) read a paper on Athletics in Relation to Disease. In the course of his remarks he said that when the twisting or wrenching violence was sufficient to overstretch the ligaments of a joint but not to tear them, so that the only symptoms were pain and impaired movement, the condition was known as "strain." When laceration resulted and there was bleeding into the tissues, and added to the pain and loss of function they had swelling, the term "sprain" was used. Sprains were divided into articular and muscular. Articular sprains might be simple or they might be complicated by fracture or gross injury to nerves or by semi-luxations in the joints. When the sprain was complicated by an injury to the bone entering directly into the joint it was called a sprain-fracture or fracture-sprain. If in addition to the sprain of a joint there was a fracture of one of the bones in the immediate neighbourhood but not involving the joint itself the expression sprain with fracture might be used. That classification for clinical purposes was a convenient one, especially when treatment was considered. In the simplest variety known as strain the patient came complaining of pain and loss of power. The pain might be very intense. The first desideratum of treatment was relief of pain, and nothing succeeded so well as rest to the injured part, and that was best obtained by means of strapping. Various forms of plaster were used for that; the best, he thought, were leucoplast and wash-leather plaster. Massage over the plaster would expedite the cure in the later stages. When, however, there was swelling coming on immediately it was due to hæmorrhage; when later, by some hours, it was due to serous effusion and was known as deferred swelling. The first requirement was that the effusion should be prevented or checked, and when it did exist to assist by every means its reabsorption. Electric pressure was as useful for these cases as it was in contusions and should be applied as soon as possible. If the surgeon was fortunate in seeing the case early he might be able to limit the bleeding considerably and might certainly prevent in a great measure the serous effusion coming on later. Speaking generally, every hour saved before treatment was begun meant a saving of days in the total period of treatment. Fixed apparatuses and rigid splints should never be used. Joints were designed for movement and should never therefore be treated like fractured bones. A joint which was left alone untreated would in the long run do even better than one that was kept in splints for a considerable time. Examples of that were often to be found in the sprains in the lower animals. The system of placing sprained joints and retaining them in splints for considerable periods was to his mind responsible for the fact that thousands of well-to-do and well-educated people as well as poorer folk flocked daily to the bone-setters and other irresponsible and unregistered practitioners. The bone-setter who moved everything by rule-of-thumb would seem to be even more successful by his haphazard methods if they were to judge by his present-day almost universal popularity. Yet both systems, the fixed and the movable, or the orthodox and unorthodox, would seem to be wanting in something. A scientific discrimination was absolutely necessary if success was commonly to follow treatment, for each case must be judged according to its merits. The once prevalent idea that every injured joint required rest was dying hard, just as it was to be hoped that the more modern idea that everything should be moved would find its limitations, for to subject every injury to early massage and movement would be found to be no less injurious. And more particularly was that true when they took sprain-fractures into consideration, and those sprains which were complicated with gross injuries to nerves. Early massage and movements might do much harm by increasing bony callus and thereby producing stiffness of the joints in cases where there was fracture, and the recent and now almost universal employment of the x rays had taught them that a great many injuries formerly regarded as simple sprain were in reality sprain-fracture.

Dr. W. COLLIER (Oxford) said that he always advised an undergraduate to let his athletic career be a short one, as his early athletic struggles developed well-marked hypertrophy of the left ventricle and there was always a danger that if he continued his efforts over too long a period he ran a very decided risk of inducing a dilatation of the aorta which might end in incompetence of the aortic valves.

Sir LAUDER BRUNTON said that they did not yet know how far albuminuria caused by over-exertion might ultimately lead to kidney damage but he did not think that that was likely to be of much importance because the organ that was most likely to suffer first was the heart and alterations in it would probably prevent the indulgence of athletics to any great extent before the kidney itself had suffered. It was, however, clear that athletics without previous training might be very injurious, and that over-strain, especially in growing boys, might lead to cardiac weakness which might ruin their future lives. It was therefore very advisable that all those who took part in athletics, whatever their age or their sex might be, should be subjected to careful medical examination unless they were willing to take the risk of doing themselves great damage. Such examination was all the more important if athletics, gymnastics, and physical training were introduced as part of the curriculum in all schools.

Dr. SAMUEL WEST pointed out that if massage of a sprained joint caused pain that persisted, then such treatment was doing harm.

Dr. F. DE HAVILLAND HALL described how dilatation of the heart might occur in cycling, horse-riding, and in athletic competitions.

Dr. A. F. VOELCKER considered that they must distinguish in athletics the different forms according to their gravity from a medical point of view.

The PRESIDENT described a case in which the patient fractured the right humerus when throwing a cricket-ball, and Mr. WHITELOCKE replied.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

The Therapeutic Uses of Sea Water.—Treatment of Rheumatic Affections by Counter-irritation of the Spine.

A MEETING of this society was held on Dec. 9th, Mr. ERNEST SOLLY (Harrogate), the President, being in the chair.

Dr. ARTHUR W. BRODRIBB (Hastings) read a paper entitled "The Therapeutic Uses of Sea Water." In explaining the choice of his subject he commented on the lack of enterprise of the South Coast towns in not making a greater use of sea water for therapeutic purposes, and said that it was done very largely abroad, particularly for scrofulous diseases and diseases of the female generative organs. He was of opinion that sea water might be applied as douches, sprays, and brine baths, after dilution or concentration for the benefit of other diseases, such as rheumatism, joint exudations, glandular enlargements, some skin diseases, and particularly for diseases of the respiratory tract, the last owing to climatic advantages.—Dr. A. F. STREET (Westgate) said that the argument as to the undoubted utility of treatment by the water of inland spas applied quite as forcibly to that by sea water, with or without the addition of seaweed. It was not right to question the value of the latter any more than that of the former, merely because ir-excess of the general mortality; this occurs at all ages and is most marked in Saxony at almost every age, is less marked in the Gotha experience, but only occurs after age 40 in Würtemberg.

MORTALITY OF MEDICAL MEN COMPARED TO NORMAL (= 100).

Ages.	Gotha insured.	Saxony.	Würtemberg.
26 to 45	125·9	124·6	92·4
46 ,, 65	109·6	128·9	117·8
26 ,, 65	114·1	127·5	107·8

There is but little difference between the mortality of town and country practitioners, the place of residence having much less influence than the conditions of the profession. Westergaard found the same fact in his investigations among Danish medical men. Karup and Gollmer consider the excessive mortality to be due to professional risks—e.g., exposure to typhoid fever, unfavourable conditions of weather and temperature, and the incessant activity of the profession. Looking at the mortality from individual causes, practising physicians show the excess chiefly in respiratory diseases (including pulmonary tuberculosis), in apoplexy, and in typhoid fever. The mortality from tubercle is 106·7 per cent. of the expected mortality, that from infectious diseases no less than 131 per cent. Among minor points brought out are the two following:—Radestock's continuation of Geissler's Saxon investigations indicates a slight rise in the expectation of life for medical men; the Gotha figures show that the mortality of medical lecturers in the universities closely resembles that of medical men generally."

MILTON'S BLINDNESS.

John Milton is generally supposed to have suffered from amaurosis, of which the old name was *gutta serena*. In the great autobiographical opening to Book III. of "Paradise Lost" the blind poet, apostrophising Light, plays on the Latin name in well-known lines:

> "Thee I revisit safe,
> And feel thy sov'reign vital lamp; but thou
> Revisit'st not these eyes, that roll in vain
> To find thy piercing ray, and find no dawn;
> So thick a drop serene hath quench'd their orbs,
> Or dim suffusion veil'd."

According to others, among whom was his late biographer, Leslie Stephen, Milton's complete loss of eyesight was due to glaucoma. To judge from the passage above quoted, the poet himself was not entirely convinced of the nature of his disease, though he gloried in the fact that he had incurred it in the service of his country. The lines seem to express alternative etiologies. The darkness fell upon him soon after his completion of the "Defensio Populi Anglicani" in 1654. "Paradise Lost," therefore, was the *magnum opus* of a blind man. Now, though such an affliction as complete loss of the use of a sense might be supposed to militate against the highest kind of achievement in art, it is a question whether in Milton's case such loss did not enhance his performance. According to Jonathan Richardson, who wrote when Miltonic tradition was still quite fresh, the poet dictated his poem in snatches between 1658 and 1662—ten lines to a chance caller, 20 lines to his daughter Anne whom he would wake up in his grim paternal fashion to act as his amanuensis during the hours of a sleepless night. According to a tradition traced to the third Mrs. Milton the poet dictated his poem, in batches of some 300 lines at a time, after rising in the early morning. These batches were composed during night vigils. Whichever tradition we accept, the fact remains that Milton's great epic was recited and dictated; it was the work of a *trouvère* of supreme genius; it owed nothing in the first instance to the restraining influences of the pen. Hence the Miltonic harmonies, the stresses, *cæsuras*, crowded syllables, pauses, which lend the poem its peculiar majesty and charm. Blindness for once may be said to have been beneficent when we consider the manner in which "Paradise Lost" was composed. Milton's insomnia deserves a word in passing. He was a man with memories when he began the composition of his poem at the age of 50 years, and these with his gout and his active mind may well have kept him awake or awakened him in the small hours. But his regimen was a starveling one, his dinner often consisting of olives. And he went to bed at nine like a man of great age.

ANIMATED PHOTOGRAPHY IN NATURAL COLOURS.

ON Wednesday evening, Dec. 9th, there was a crowded meeting at the Royal Society of Arts, London, to hear an interesting lecture given by Mr. G. Albert Smith, F.R.A.S., on Kinematography in Natural Colours. Sir J. C. Lamb, C.B., C.M.G., presided. In THE LANCET of May 9th last (p. 1358) we recorded a demonstration of Mr. Smith's invention which was given at Urbanora House, London, under the auspices of Mr. Charles Urban, F.Z.S., who has greatly assisted Mr. Smith in his endeavours. Mr. Smith now showed what progress he had made in the interval and his results when thrown upon the screen were received with much applause. Mr. Smith explained in outline the three-colour theory and said that six years ago when Mr. Urban invited him to take part with him in a series of experiments to obtain animated photography in colours it was upon that principle that the experiments were undertaken, but a difficulty was found in superimposing the three colour pictures as they could not be made to "register" accurately, and it was decided to try to make them superimpose in the mind of the observer by running the film through the machine very fast. This was an improvement but the colours were extremely pale, in fact, washy. Mr. Smith then set to work to make a film sensitive to all colours, especially red, and to reduce the records necessary from three to two, because in using three colours they cannot be replaced quickly enough to obtain the superimposition. It was necessary also to devise a scheme which could be readily adapted to all existing kinematographs and bioscopes and to the ordinary standard film of the usual perforation. Eventually Mr. Smith succeeded in making a sensitised film which when exposed with the use of small rotating transparent coloured screens inserted in front of or behind the lens of the camera filtered the light and recorded, in a scale of greys ranging from white to black, on one film, the corresponding range of colour. This record is a record of colour sensation as the spiral on the phonograph cylinder is a record of sound waves. In Mr. Smith's words, "the colour is there in black and white." White represents white, yellow is represented by a slight tinge of grey, and for the other colours the records get darker and darker till they get down to black. From these films or colour records the original colours are reproduced on the screen (sheet) by the optical lantern with the interposition of the rotating coloured disc, as described in THE LANCET of May 9th. This range of colours Mr. Smith has been able to represent in two records by having in the camera a revolving shutter with scarlet and blue-green portions alternately arranged. Through the scarlet shutter he records white, yellow, orange, and reds. Through the blue-green shutter he records white, yellow (again), green, and a little blue. Only a little blue is required, as too much blue is mischievous and gives very pale colours. These pictures are taken at the rate of 32 per second and they must be taken in the bright sunshine. This rate is twice that necessary for the ordinary black and white films. Mr. Smith reminded his audience that very great all the greater because such a lump was nearly always painless. They did not know the laws governing the spread of cancer, and he had been particularly impressed with the danger of cutting into a cancer. For many years he had removed both pectoralis major and minor. Recurrence was rare in the site of the operation but frequently occurred in other parts of the body.

Mr. E. H. TAYLOR, in reply, said that he brought forward the communication to emphasise the importance of carrying out the most complete operation, even where the disease was of quite small dimensions, and to emphasise the importance of early diagnosis.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 3rd, Mr. R. F. Jowers, the President, being in the chair.—Dr. Walter Broadbent showed a girl, aged 14 years, with severe Mitral Regurgitation, in whose case there was no history of rheumatic fever, chorea, or scarlet fever, but only of growing pains and pain in the feet for which she had recently been given flat-foot pads. He had brought up the case to show the necessity of examining the heart in children with "growing pains." He also showed a Stomach with Congenital Hypertrophic Stenosis of the Pylorus from a child six weeks old. The child weighed 11 pounds at birth; it was nursed by the mother. On the third day it began vomiting, and this continued up to its death. The bowels were obstinately constipated. When admitted to hospital it weighed 3½ pounds; the pylorus could not be felt and no peristalsis of the stomach was visible. It was considered too feeble for operation and died very shortly.—Dr. J. F. Gordon Dill read notes of, and showed specimens from, a case of Primary Carcinoma of the Thyroid Gland in a man aged 55 years. The man had been quite well up to a month before death, when he began to have difficulty in breathing. Two weeks later he noticed a lump in his neck, and the dyspnœa became worse with difficulty in swallowing also. The man died shortly after admission to hospital, and a tumour of the size of a Tangerine orange was found in the right lobe of the thyroid, bulging between the trachea and the œsophagus.—The President showed a Serous Cyst of the size of a bantam's egg, removed from the erector spinæ of a man who had complained of a painful lump in the small of the back for a year.—Mr. H. H. E. Scatliff read notes of a case of Atypical Leukæmia. The patient went to him for sudden hæmorrhage under the conjunctiva. He had also enlarged glands in the neck and œdema of the legs. He was very anæmic and the blood showed 2,736,000 red cells and 6300 white, but the leucocytes were found to be 96 per cent. small lymphocytes. The man became rapidly worse, having severe hæmatemesis, and died a fortnight after he was first seen.—Dr. F. G. Bushnell showed specimens of the Blood under the microscope and read a paper on this form of leukæmia, sometimes called leukanæmia. He said it was the third case that he had examined at Brighton; the total leucocytes were not increased in number but they consisted almost entirely of lymphocytes; the liver and spleen and glands were enlarged, and they and all the viscera contained large numbers of lymphocytes. The course of the disease was a severe progressive anæmia akin to pernicious.—Dr. C. F. Bailey read a paper on High-Frequency Currents and their Medical Application. He said that high frequency currents caused a microscopic battering of every cell in the body, changing too quickly to cause contraction of muscle or sensation but capable of causing inhibition, anæsthesia, and blanching of the skin. He used the effleuve mainly and found it useful in pruritus and some forms of eczema, also in neuritis and myositis, and in migraine. Auto-condensation lowered vascular tension, while spinal effleuve tended to increase it and was useful in neurasthenia.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on Dec. 9th, Professor William Stephenson, the President, being in the chair.—A paper by Dr. T. M. Callender on Thyroid Extract as a Preventive of Dystocia from Large Child was read by the secretary. Dr. Callender attended a woman in her first confinement who was short and stout with a justo-minor pelvis. The child presented the right occipito-posterior position and had to be delivered with forceps with considerable difficulty. The child weighed 8½ pounds and was still-born. The patient suffered severely from coccydynia, the coccyx having been dislocated during labour and its removal was required a few months later. She afterwards became very stout and this was treated by thyroid extract and diet with good results. Having again become pregnant and as she dreaded the possibility of losing another child Dr. Callender administered thyroid extract five grains a day from the third month to interfere with the development of the child. The thyroid extract was taken almost continuously to full time, when she was delivered easily of a healthy child which weighed 6½ pounds, being two pounds less than the previous one. Dr. Callender had also given the same treatment in another case; the mother had had two very difficult labours due to the large size of the children, in one labour requiring craniotomy. Ten grains of thyroid extract were given daily and the result was a comparatively easy labour and a small child.—The President, Dr. H. Oliphant Nicholson, and Dr. J. W. Ballantyne discussed the paper.—Dr. Ballantyne read a paper on Pre-maternity Hospital Practice. He reviewed a quarter's series of cases in the Hamilton Ward for the treatment of morbid pregnancies in the Royal Maternity Hospital, Edinburgh. These included 30 cases, consisting of five of eclampsia, three of albuminuria, four of accidental hæmorrhage, three of placenta prævia, four of threatened abortion, two of retroversion of the gravid uterus, one of habitual fœtal death, two of phlebitis in pregnancy, one of heart disease in pregnancy, one of gingivitis, one of severe chorea gravidarum, one of gonorrhœal arthritis in pregnancy, one of contracted pelvis and vaginal cicatrisation, and one of twins with hydramnios of both sacs. There was only one maternal death, that of the chorea gravidarum. The number of cases shows that there exists a rapidly increasing demand among medical men for a hospital or nursing home where cases of morbid pregnancy can be suitably treated. It is also noted that many of the most serious cases occur in the first half of pregnancy. The observation and treatment of these conditions will develop an important branch of obstetrics both on medical and surgical lines. He advocated a separate building and staff for these cases but connected by corridor with the maternity hospital.—The President, Dr. A. H. F. Barbour, Dr. F. W. N. Haultain, Dr. J. Haig Ferguson, and Dr. J. Ritchie made remarks on the paper, and Dr. Ballantyne replied.

HUNTERIAN SOCIETY.—A meeting of this society was held on Dec. 9th, Dr. Arthur T. Davies, the President, being in the chair.—Dr. O. K. Williamson showed a case of Aortic Stenosis in a boy, aged eight years. Examination showed marked hypertrophy of the left ventricle, together with a harsh systolic murmur over the aortic area. Slight choreic movements were also to be observed.—Mr. Hugh M. Rigby showed: 1. A case of Popliteal Aneurysm cured by the Matas Operation. When first seen the aneurysm was of the size of a tennis ball. Symptoms had been noticed for three months and the swelling, which had grown rapidly, for four weeks. Œdema of the leg was present and pulsation was delayed in the arteries of the foot. At the operation the sac was laid open and two arterial openings were found 1½ inches apart. These were occluded by chromic gut continuous sutures. The rest of the sac was obliterated by buried chromic gut sutures. The wound healed well and there was no recurrence. The leg was still somewhat œdematous. Pulsation could not be felt in the arteries of the foot. 2. A case of Anterior Dislocation of the Foot treated by excision of the astragalus. As the result of operation the patient could walk without support and had fair movement at the ankle-joint. Before the operation the foot was held in the partly extended position and no movement was possible at the ankle-joint. 3. A case of Duct Carcinoma of the Breast, secondary deposits in the left humerus with spontaneous fracture two and a half years later. The right breast was removed for duct carcinoma in April, 1906. This had been noticed for five years. The axillary glands were not involved. The growth showed extensive mucoid degeneration. No local recurrence had taken place. Three weeks ago, after a slight effort, pain was felt in the left shoulder. A fracture was discovered in the upper part of the humerus with much swelling which a radiograph showed to be due to the presence of a new growth.—Dr. J. W. Bernstein showed: 1. A case of Polyarthritis in a woman with extreme deformity of the fingers. 2. A case of Disseminated apparent absence of facilities for the transfer of tuberculous patients from London hospitals to country institutions at a time when such patients most need it. Referring to this committee's report, the Prince of Wales remarked that if the applications received by the committee this year were to be taken as a measure of the supply of beds in the country for the consumptive poor of London, he could not help feeling that the supply was inadequate. One step towards meeting this need had already been taken by the formation of the National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis. The Benenden Sanatorium is the first outcome of this movement and His Royal Highness thought that such an effort on the part of the workers themselves to deal with this great question deserved the encouragement and support of the Fund. It should be mentioned that the London Parochial Charities have again given their annual grant of £1000 for convalescent homes and the League of Mercy will probably be able to add to the Fund £18,000.

THE IMPORTATION OF FOREIGN MEAT.

THE Local Government Board has recently issued a circular in which it is pointed out that the public health regulations in regard to foreign meat, referred to in a leading article in THE LANCET of Feb 1st, 1908, will take effect on and after Jan. 1st, 1909. It will then be the duty of the medical officer of health in every case in which notice under these regulations is received by him from the officers of Customs to decide whether meat which has been detained by those officers falls within the classes specified. If so, he is required to give a notice forbidding the removal of the meat for any purpose other than exportation. If an importer to whom a notice of the kind has been given desires not to export the meat but to use it for some purpose other than sale for human consumption, the procedure to be adopted to enable him to do so is provided in the regulations. These regulations refer to boneless meat, "boxed" meat, boxed pork, tripes, tongues, and kidneys, which, according to the category in which they are placed (Class I. or II.), are dealt with correspondingly.

A WISE SUGGESTION.

THE enormous bequests of the late Mr. Henry Isaac Barnato have included a legacy of a quarter of a million pounds to his trustees for the purpose of founding a hospital or other charitable institution in memory of his late brother, Mr. Barnett Barnato, and his late nephew, Mr. Woolf Joel. The application of this fund is to be vested in the sole hands of the trustees. A correspondent in the *Daily Telegraph* has pointed out that if this magnificent sum is to form the endowment as well as the building fund of a hospital the Weir bequest controversy of large *versus* small hospitals will be revived. In a subsequent issue of the same paper Mrs. Watt Smyth makes the suggestion that the money should be spent in constructing and endowing a bungalow hospital settlement in hygienic country surroundings for the open-air treatment of school children found by medical inspection to be suffering from pulmonary tuberculosis. She gives evidence to show that this disease will be diagnosed in an appreciable number of children attending elementary schools, and accepting her estimate of 1 per cent. (which was obtained in a London school of which Mrs. Watt Smyth is a manager) it is obvious that their treatment will shortly become a serious problem. For the sake of the suffering children themselves, as well as of their schoolfellows and their families, it is very desirable that they shall be treated in a special hospital settlement and we commend Mrs. Watt Smyth's timely suggestion to the careful consideration of the administrators of the Barnato trust.

FLIES AS A NUISANCE.

A REPORT by Dr. W. H. Hamer presented to the London County Council on the extent to which fly nuisance is produced in London by accumulations of offensive matter was ordered to be printed in October and is of great interest. A similar inquiry was undertaken in 1907, the results of which were printed in January of 1908. Upon this we commented in our issue of March 21st, p. 876. The present report is upon the same lines as the former, being illustrated with curves and diagrams. In 1908 the places of observation were 141 surrounding nine sets of premises—namely, "four depôts, at three of which stable manure or house refuse, or both, were manipulated; two stable premises, a cowshed, a glue and size manufacturer's premises, and a jam factory." In 1907 the places of observation numbered 163 surrounding 12 centres of practically the same nature as in 1908, except for the addition of a cattle market. The various kinds of flies were in both years nearly all—i.e., nine-tenths—Musca domestica; there were also a few bluebottles and a fair number of the Homolomyia canicularis which closely resembles Musca domestica but is smaller. There was one curious difference, however, in the two years. In 1907 no instance of Stomoxys calcitrans, a biting fly, was found, while in 1908 at one station (No. 7), a cowshed, the stomoxys was found in large quantities. A few were also found at No. 6 station which was stables. As regards the question of the carriage of the infection of diarrhœa by flies Dr. Hamer says:—

> Comparison of the curves for 1908 and 1907 brings to light, moreover, a striking fact regarding the behaviour of the fly and diarrhœa curves in the two years. From the middle of August to the end of the first week of October, 1907, the number of flies was practically stationary. Again from September 4th to October 5th, 1908, the number of flies was also practically stationary. Further, judging by the total number of flies caught, in relation to the number of places of observation in 1907 and 1908, practically the same extent of prevalence of flies (in the parts of London concerned) was maintained during these two stationary periods of the two years in question. Yet during the stationary period of 1907 diarrhœa was steadily increasing, while during the stationary period of 1908 diarrhœa was steadily declining. In order to explain this phenomenon on the fly hypothesis, it becomes, therefore, as has been already surmised, necessary to assume that in determining variations in amount of diarrhœa, importance attaches not so much to the number of carriers of diarrhœa organisms, as to the extent of distribution of the organism itself. If this be admitted, however, it is (on the assumption that flies cause diarrhœa) clear that precise correspondence of the carrier curve—i.e., the fly curve—and the diarrhœa curve cannot be expected to occur.

And Sir Shirley F. Murphy in his introduction says:—

> The report also refers to the question of diarrhœa. No final decision can be given, but in the present state of knowledge it appears desirable to maintain a critical attitude as regards acceptance of the view that the fly acts as a carrier of the diarrhœa organism.

MENINGEAL HÆMORRHAGE IN ACUTE RHEUMATISM.

AT a meeting of the Société Médicale des Hôpitaux of Paris on Nov. 13th M. Moutard Martin and M. Pierre Weil reported a case of a very rare complication of acute rheumatism—meningeal hæmorrhage. A woman, aged 36 years, was admitted into hospital on Oct. 26th, 1907, for a third attack of rheumatism. She had always been delicate. In 1905 she had acute rheumatism and again in July, 1907. Her present attack began on Oct. 20th with a chill and sore throat. The shoulder-, elbow-, and wrist-joints were attacked and there were intense headache and vomiting. On admission the temperature was 100·4° F. and the joints mentioned were red, hot, swollen, and very tender. The heart was normal and the urine did not contain albumin. Under sodium salicylate the pains diminished and became limited to the right wrist and the temperature fell to 99·5°. On Nov. 18th the wrist was still swollen and painful and the temperature was about 99·5°. On the 22nd the patient was and was an early contribution to its return to favour after the desuetude into which it had fallen as a reaction from its excessive use in earlier times. Some remarkable cases are instanced of its value in chronic renal disease and in convulsions due to high arterial tension without disease of the kidneys. Several papers deal with disease of the respiratory organs; among them we may mention those on Pneumonia; on Interlobar Empyema; on Some Points in the Clinical History of Effusion into the Pleural Cavity; and on a case of Hydatids of the Right Lung Simulating Pneumothorax. It is difficult to realise that the paper on pleural effusion was written so long ago as 1881. An interesting point which is emphasised by Sir William Broadbent is that in cases where the signs indicate incomplete collapse of the lung—i.e., where loud bronchial breathing is heard all over the affected side—paracentesis is usually not necessary, since there is often not a great quantity of fluid and the cases recover spontaneously. The case of hydatid of the lung simulating pneumothorax is reprinted from the second volume of THE LANCET of 1878 and is an interesting illustration of the lucid and critical manner in which Sir William Broadbent recorded his cases and applied the pathological data obtained at the necropsy to the explanation of the clinical phenomena observed during life.

Within the short compass of a review it is impossible to mention all the subjects included in this volume owing to the wide range which they cover but we may refer to a few more of them. An address on Dilatation of the Stomach contains a useful account of the treatment of that condition. A clinical lecture on Sleeplessness, delivered in 1900 and recorded in our columns, is an interesting study of some of the protean forms of that distressing condition and abounds in common-sense hints as to treatment.

A considerable section of the book is devoted to Sir William Broadbent's papers on neurological subjects and, as is most fitting, the first of these is the remarkable paper published in 1866 in which the theory, now known by the name of its distinguished author, was first propounded of the existence of commissural connexions between the nuclei governing the action of bilaterally associated muscles. This paper is one of the most striking in the whole book and should be read by all who are interested in the history of neurology as an example of clear reasoning and thoughtful suggestion. Several papers deal with the subject of Aphasia, another with that of Epilepsy. The latter was delivered in the form of a lecture and gives an interesting account of that condition and its treatment. The Lettsomian lectures for 1874 on Syphilitic Affections of the Nervous System bring the volume to a close.

We can cordially commend this book to our readers, not only for its historical interest but also for the really valuable information in which it abounds. Dr. Walter Broadbent is to be congratulated on the choice which he has made from his father's writings, and the book which he has produced will certainly become a medical classic.

A Manual of Natural Therapy. By THOMAS D. LUKE, M.D. R.U.I., F.R.C.S. Edin. With 30 plates and 125 illustrations. Bristol: John Wright and Sons, Limited. 1908. Pp. 303. Price 7*s.* 6*d.* net.

THIS volume is intended to give an account of the use of water, heat, light, massage, electricity, and diet in the treatment of disease. The author, in his preface, modestly states that in the preparation of the work no attempt has been made to give a complete or exhaustive account of any of the departments dealt with, but he has endeavoured to embody the chief points of interest and importance briefly and succinctly, in such a manner as to awaken interest and to lead to further study and consideration of the methods treated of on the part of the reader. Dr. Luke would have acted more wisely had he modified some of his expressions of opinion on the use of drugs. For instance, the following remarks cannot altogether be taken as exact statements of the present conditions existing in hospitals: "Going round a medical ward one cannot help being struck by the absence of long prescriptions, once so common, on the patient's bed-card. These are now seldom seen. There is the chart with respiration and pulse-rate, the temperature, blood-count, &c., and possibly away in the corner, in very small writing, 'Hæmatogen ʒi. t.i.d.,' or 'Nuclein gr.ii.,' or 'Thyroidectin gr.v.' On all the bed-cards the British Pharmacopœia takes a minor place." Then, again, an imaginary picture is drawn of what Dr. Luke would apparently wish his readers to believe takes place in most medical wards: "At one bed we see a man, with a pallid, puffy face, lying in a bed vapour bath; at another an electrician is galvanising a case of exophthalmic goitre from 'the main'; and as we leave the ward we notice a fair-haired Norseman enter, and we are told that he is the masseur, who pays a daily visit." Dr. Luke mentions the exceptions to the patients usually seen in the medical wards of a general hospital and seems to hint that such cases are much more common than is really the case.

Accepting "natural therapy" at its true worth we can give all praise to Dr. Luke's work as affording a good description of the various methods and appliances necessary for the numerous processes which may be carried out at the recognised spas or in private houses or institutions. The *rationale* of the use of mechanical means is explained in a scientific manner and the indications for the use of baths, heat, cold, massage, or electricity are fully and carefully considered. It is perhaps doubtful whether the proper and suitable application of hydrotherapy, thermotherapy, "massotherapy," and electricity is fully appreciated by the general mass of practitioners and a volume of this nature will be welcomed.

The book is of moderate size and the manner in which it is written renders it easy to read and to understand. The illustrations are numerous and good and add considerably to the value of the letterpress. Those of our readers who wish to increase their knowledge of mechanical therapeutics cannot do better than consult its pages.

Tuberculosis in Infancy and Childhood, its Pathology, Prevention, and Treatment. By Various Writers. Edited by T. N. KELYNACK, M.D. Vict., M.R.C.P. Lond., Physician to the Infants Hospital, Westminster; Physician to Mount Vernon Hospital for Consumption and Diseases of the Chest. London: Baillière, Tindall, and Cox. 1908. Pp. 376. Price 12*s.* 6*d.*

THE *British Journal of Tuberculosis* for July, 1907, formed a special number devoted to the consideration of Tuberculosis in Infancy and Childhood, and contained signed articles by well-known authorities dealing with various aspects of the question. This volume is an expansion of the series of articles contained in that journal. The list of contributors is a long one, containing 38 names of English, American, and continental observers.

In his introductory remarks Dr. Kelynack draws attention to some of the problems of tuberculosis which are still under discussion. He rightly expresses surprise that in the conduct of the antituberculosis campaign measures for the systematic study, organised prophylaxis, and adequate treatment of tuberculosis in early life should hitherto have received but little attention. This has been more particularly the case in this country than in some continental countries, especially France, where sanatoriums for "consumptive children" are numerous. A work of the kind now before us is therefore welcome, as it treats of tuberculosis

THE SEX-CENTENARY DINNER OF THE WORSHIPFUL COMPANY OF BARBERS OF LONDON.

THE sex-centenary dinner of the Worshipful Company of Barbers of London was held on Tuesday evening, Dec. 15th, at Grocers' Hall, the Grocers' Company having placed their famous premises at the disposal of the Barbers for the important occasion. The Master, Sir JOHN TWEEDY, F.R.C.S., presided, and, as might be expected in the circumstances, there was an important medical element among the numerous guests. Those present included Sir R. Douglas Powell (President of the Royal College of Physicians of London), Mr. Henry Morris (President of the Royal College of Surgeons of England), Sir Frederick Treves, Sir William J. Collins, M.P. (Vice Chancellor of the University of London), Mr. Howard Marsh (Master of Downing College, Cambridge), Dr. W. Collingridge (medical officer of health of the City of London), Mr. F. Gordon Browne (Master of the Society of Apothecaries), Sir Thomas Smith (Sergeant-Surgeon to the King), Inspector-General J. Porter (Director-General of the Royal Navy Medical Service), Surgeon-General Sir Alfred Keogh (Director-General of the Army Medical Service), Sir T. Clifford Allbutt (Regius Professor of Physic at the University of Cambridge), Sir W. S. Church (President of the Royal Society of Medicine), Mr. C. B. Lockwood (President of the Medical Society of London), Sir Henry Norbury, Sir Jonathan Hutchinson, Sir James Reid, Sir W. Watson Cheyne, Mr. Thomas Bryant, Dr. D. Ferrier, Mr. A. A. Bowlby, Mr. H. T. Butlin, Mr. W. Arbuthnot Lane, Mr. A. Pearce Gould, Dr. F. T. Roberts, Alderman Sir T. B. Crosby, Mr. H. H. Clutton, Mr. Edmund Owen, Mr. C. W. Mansell Moullin, Mr. W. Bruce Clarke, Dr. J. F. Payne, Mr. A. W. Mayo Robson, Mr. J. H. Morgan, Mr. R. J. Godlee, Dr. S. West, Mr. G. H. Makins, Dr. Dawson Williams (Editor of the *British Medical Journal*), and Dr. Squire Sprigge (THE LANCET). The laymen included the Bishop of Oxford, Sir Robert Ball, Sir Thomas Sutherland, Sir R. Macgregor Stewart (Lieutenant of the Tower), Sir Forrest Fulton (Recorder of London), Mr. E. J. Gregory, R.A., Mr. Anthony Hope Hawkins, the Masters of the Grocers', Mercers', Ironmongers', and Skinners' Companies, Sir John Furley, Mr. F. C. Lingard (clerk to the Company of Barbers), and the Wardens of the Company.

After the usual loyal toasts the MASTER proposed "The Corporation of London and the City Guilds" in an eloquent speech in which he traced the growth in strength and power of the guilds and showed how London and her guilds had always fought the battle of England for freedom and progress. Sir John Tweedy made special and eloquent allusion to the fact that the Areopagitica, that magnificent vindication of the freedom of the press, was written in the City of London, and that, later, it was one of the Members of Parliament for the City whose brave action, supported by his constituency, first made possible the publication in the press of proceedings in Parliament. Sir John Tweedy's speech was punctuated throughout with applause and was felt by all to be a great performance. The toast having been replied to in suitable terms by Mr. Alderman and Sheriff HANSON in the absence of the Lord Mayor of London, the MASTER then proposed the toast of "The Medical Profession," selecting especially the work of preventive medicine for favourable notice. The toast was replied to by Sir R. DOUGLAS POWELL and Mr. HENRY MORRIS.

Mr. D'ARCY POWER then proposed the toast of "The Worshipful Company of Barbers" in an excellent speech in which he traced the connexion between surgery and barbery. He said: I rise with considerable diffidence to propose this toast, indeed my diffidence might have proved insurmountable if I had not thought that it was a duty owing to the position I hold which made it imperative for me to do so. As surgeon to St. Bartholomew's Hospital and lecturer there on surgery conjointly with my friend, Mr. Bruce Clarke, I hold a position which was held by some of the most renowned surgeons in the annals of this Company of Barbers whose honoured guests we are this evening: Thomas Vicary, your first master, Clowes, Gale, Woodall, Charles Bernard, and Percivall Pott. I am not going to weary you with any long discourse on the historical aspects of surgery in relation to the barbers, but I should like to say at once that I believe we as surgeons owe our present position and the esteem in which we are held very largely to the action of the Barbers' Company in the remote past. I mean, of course, pure surgery, consulting and operating, such as is practised by the majority of my professional brethren who are here this evening. To prove this and to show how much we owe to the barbers we must consider shortly what we were, how we were helped, and what we became. For our purposes London may be taken to represent England, because what was true of London was equally true, so far as we know, of the larger and older towns in the provinces, Oxford, Bristol, Exeter, York, Newcastle, all had a few surgeons and after a time a barber surgeons guild. In London, then, from the beginning of civic history there were two groups of men, barbers who shaved, did minor operations and were general practitioners, and surgeons who undertook what we should now call pure surgery, though there is no doubt that they often meddled in physic, just as in many country towns to this day the surgeon to the county hospital will treat a case of pneumonia if he is summoned to attend it. But, broadly speaking, the barbers were tradesmen keeping shops; the surgeons, being the more expert, having a wider outlook, and often having a scientific mind, more nearly approached the standard of a profession. These pure surgeons were not very numerous and for the most part they attained their superior dexterity in the wars which were so numerous when England was only a small part of a large continental kingdom. The barbers were more numerous but the surgeons made up in influence what they lacked in numbers. Wounds and their prolonged treatment necessarily brought the surgeon into very intimate relationship with the great nobles who led our forces in wartime and you will remember that when armour was worn and tournaments were frequent it was the leaders who suffered much more than the common people. It often happened, therefore, in the rough and tumble of camp life that the nobleman became the personal friend of his surgeon, especially if the surgeon were a good fellow and had been successful in his cure, so that when peace came and they were all at home again the surgeon had a powerful friend at court who was able and willing to do him many a good turn. It thus happened that the surgeon was a person of influence at a time when many unconstitutional acts went by favour. The barbers, on the other hand, stayed at home, became good citizens, amassed fortunes for themselves, and in so doing became first-rate men of business. The surgeons necessarily had the defects of their good qualities. They led a roaming and joyous existence, intervals of hard work or disaster being mingled with periods of ease and the riot of plunder. In nothing is this better seen than in the question of fees. The barber worked steadily with the help of his apprentices, put the proceeds into the till, and ventured them in trade. The surgeon received his pay when he could get it. Nominally, in 1415, for instance, it was twelvepence a day, but he probably only got the money when the King or his leader happened to be in funds and as often as not it was in arrear and very often he never got it at all. He was paid in kind for personal services, sometimes, as we learn, an ambling horse and a diamond ring worth 30 crowns, at another time a tun of wine and more when finished, and at another time "an honest present." Very rarely do we meet with a surgeon who was capable of making a bargain. I only know of one, and he lived a generation after Richard the Barbour, whose memory we are assembled here this evening to honour. John of Ardern, who was a North-countryman living in London in 1360, says that for the cure of a fistula, "when it is curable, ask of a worthy man and a great an hundred marks or forty pound with robes and fees of an hundred shillings term of life by year. Of less men forty pounds or forty marks ask he without fees. And take he not less than an hundred shillings for never in all my life took I less than an hundred shillings for cure of that sickness." His business capacity is further shown in the advice which he gives about fees, for he says: "Ask boldly more or less, but ever beware of scarce asking, for overscarce asking setteth at nought both the market and the thing." But places. People who take pleasure in reading of the recreations of public men will find that they still range from mountaineering and music to serendipity (which means, we believe, buying and selling curios). We read that one Roman spirit finds its ease in "public duties"—a recreation which we trust will be noted widely. We will say, as we have said before, that "Who's Who" is well-nigh indispensable in a newspaper office, for it gives that accurate information about the careers of all sorts of public people to which all journalists require convenient access. The few biographies of eminent foreign men are very welcome, although their number obviously must be limited. "Who's Who Year Book" contains *inter alia* lists of public office holders, including the staffs of the London general hospitals, and a condensed "peerage." "The Englishwoman's Year Book" claims, with good reason, that "no woman who takes any part in public or social life can afford to be without it, especially in view of the great Renaissance of women." It includes complete and practical accounts of the trades and professions open to women and the means of entering them. Lists of women's clubs, girls' schools, public offices held by women, and much other matter are included. The "General Prospects" section heading the chapter on "Medicine, Pharmacy, and Dentistry" is an abstract of Dr. Mary Thorne's address on "Medical Women and their Prospects" at the Conference of Women-Workers held at Westminster this year. "The Writers' and Artists' Year Book" contains lists with details of English journals and magazines, literary and art publishers, printers, and agents, and other matter including a guide to authors on the correction of proofs.

Diaries for 1909:—We have received Messrs. Walker and Co.'s annual batch of pocket diaries for 1909, with two larger scribbling diaries for desk use. Most of the pocket diaries are printed so as to allow of a week's entries at each opening, but some allot a whole page to each day. The former, which are more generally convenient, are made in several sizes and are bound in cloth, leather, and skin of various kinds. Some of the covers are fitted inside with pockets for stamps and cards. The diaries include pages ruled for a monthly cash account on a system which, as we can testify from experience, is clearly and simply arranged. Diaries Nos. 4 and 7, bound in pigskin or Russian leather, strike us as being particularly attractive. Small waistcoat pocket diaries are included amongst the batch. Any size of diary issued by Messrs. Walker can be obtained in any of their bindings. An insurance coupon against various accidents is a feature common to these publications and to the handy "Letts's Diaries" issued by Messrs. Cassell and Co., who have sent us samples and ask us to state that they are the sole publishers of these little books. One of them is a cloth bound pocket medical diary that is really suited for the pocket, being much thinner and neater than most of such publications. A bulkier form of it is issued in a leather binding. Messrs. John Wright and Sons (Bristol) have also sent us their "Physicians' and Surgeons' and Consultants' Visiting List (Form A) for 1909" (sixteenth edition). This book is well known to many of our readers. By a system of interposing half leaves between the pages it enables an entry for a visit on every day in the month to be made in a different square against a patient's name, the record for the whole month being shown at one opening. We recommend this diary as practical and useful.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. Vol. II., No. 1, November. London: Longmans, Green, and Co.—This volume is opened by the report of the committee the Royal Society of Medicine upon the resuscitation of the apparently drowned which we reviewed in an annotation on Dec. 5th. Following this report the proceedings of the Section for the Study of Disease in Children make their first appearance, the contributions including clinical reports of cases by Dr. F. W. Higgs, Dr. J. P. Parkinson, Dr. C. W. Chapman, Dr. E. Cautley, Mr. D. C. L. Fitzwilliams, and Dr. G. Carpenter, president of the section, who describes two cases of microcephaly. Dr. F. J. Poynton, with Dr. W. Jeffrey, reports two cases of post-basic meningitis with recovery after injection of Ruppel's serum and one fatal case treated similarly. Dr. Poynton also describes with Dr. R. H. Miller specimens from a case of cleido-cranial dysostosis. In the Clinical Section cases are reported by Mr. W. S. Handley, Dr. A. Stanley Green, Mr. R. G. Hann, with Dr. H. Lambert Lack, Dr. Poynton, Mr. Percy Flemming, and Mr. Raymond Johnson. The Dermatological Section is occupied by cases by Dr. H. G. Adamson, Mr. T. J. P. Hartigan, Mr. W. Stuart-Low, Dr. E. Graham Little, Sir Malcolm Morris with Dr. S. E. Dore, Mr. G. Pernet, and Dr. J. H. Sequeira. The Electro-Therapeutical Section prints the report by the president, Mr. W. D. Butcher, on the Fourth International Congress of Medical Electrology and Radiology at Amsterdam. The Epidemiological Section is occupied with an important paper on Season and Disease, by Dr O. H. Peters, with the discussion which it evoked. The Medical Section publishes Captain R. McCarrison's careful observations on Endemic Cretinism in the Chitral and Gilgit Valleys, which our readers will remember. The Neurological Section opens with a study of Two Anomalous Cases of Syringomyelia, by Dr. Gordon M. Holmes and Dr. R. F. Kennedy. Other cases by Dr. F. E. Batten illustrate the sequel to a Cerebellar Atrophy and Diffuse Sarcomatosis of the Brain and Spinal Cord. Dr. S. A. K. Wilson describes the pathological condition in two cases of Tabetic Amyotrophy. The Obstetrical and Gynæcological Section contains a paper (including some remarkable illustrations) on Dystocia due to Distension of the Urinary Bladder of the Fœtus, with remarks on Renal Secretion in Utero, by Dr. J. E. Spicer. Other case records are by Mr. Alban H. G. Doran, Dr. Cuthbert Lockyer, Dr. A. H. N. Lewers, and Mrs. Scharlieb, M.D. The Odontological Section reports a Mechanical Device for Amalgamating Alloys, communicated by Mr. W. F. Mellersh and an abstract of Mr. W. Wright's paper on the Teeth of Early Man. In the Pathological Section Mr. P. N. Panton describes an Investigation into some Aspects of the Action of Arsenic on the Blood (especially as regards Phagocytosis), the Bone Marrow, and Certain Viscera. Mr. R. L. Knaggs and Dr. O. C. Grüner report a rare case of Bone Disease, and Dr. J. Burton Cleland contribute a note on Melanotic Deposits in Cattle and Sheep. The Surgical Section contains one long paper on Traumatic Rupture of the Intestine by Mr. James Berry and Mr. P. L. Giuseppi. It is compiled with great care and contains a valuable analysis of 132 cases that have occurred in ten London hospitals from 1893 to 1907. The Therapeutical and Pharmacological Section publishes Dr. Nestor Tirard's address on the Scope and Object of the British Pharmacopœia.

The Hospital Gazettes.—The chief contributions to the November number of the *Guy's Hospital Gazette* have been further instalments of "Notes by a Roving Guy's Man," dealing with continental clinics in a breezy but informative manner. *The London Hospital Gazette* (December) again shows its interest in natural history by giving precedence to an article by "P. H. B." on the Sea Birds' Home—to wit, the Island of Handa—and by an account of the vegetable colonisation of coral atolls from "F. W. J." *St. Bartholomew's Hospital Journal* (December) contains a continuation closing contracture and an anodal closing contracture was the coefficient of polarity. Under pathological conditions these coefficients were disturbed, but with a return to health the relationship was restored. These were very clearly explained and demonstrated and should prove of great value in diagnosis and prognosis.

Dr. VERAJUTH (Zürich) read a paper on Psycho-galvanic Reflex Phenomena. By means of an electrode in each hand and a Deprez galvanometer in shunt any psychical excitation caused a deviation, but for demonstration purposes it was advisable to pass a mild constant current from hand to hand, when instead of a deviation there was an alteration of the existing deflection. He attributed this change in resistance to the sweat glands which were readily influenced by psychic emotion.

Dr. DUYVENSZ (Amsterdam) demonstrated his method of examination of teeth by means of a faradic sledge coil. One electrode was held by the patient, and the coil being set in action the other electrode, of specially convenient form, was applied to the suspected tooth. The secondary was then pushed over the primary until the first suspicions of pain were experienced by the patient. The position of the secondary was noted and a similar examination was made of the corresponding tooth of the opposite side. In this manner the most accurate examination could be made and the method was applicable to other parts of the body.

It was not until he had got fairly under way with his paper on the Electric Resistance of the Human Body that the Congress discovered that Professor LEDUC (Nantes) had a surprise in store for them. After relating the difficulties in ascertaining this and the great discrepancy in the results obtained, which were supposed to be due to polarisation at the electrodes, he first by some simple experiments proved how little influence moisture, anæmia, congestion, or temperature had on the resistance of the skin. He then went on to show that the only really effective part of a flat electrode was its circumference, and it was this and not the surface area which determined the resistance between any two points. That is to say, that for all the use that the central part of such an electrode was it might as well be removed, leaving a ring or hollow square or parallelogram. By means of lantern slides coated with gelatin and potassium ferrocyanide and iron electrodes he demonstrated exactly what took place with ring and plate electrodes, the change of colour showing this very clearly. Underneath the plate electrodes there was practically no change in colour and the changes in resistance were inversely as the circumference of the electrodes.

Later, after papers by Dr. ZANIETOWSKY on Electric Baths and Iono-therapy, in which it was shown that baths were not suited for the introduction of ions into the body, Professor LEDUC had a splendid opportunity of driving home his contention that the periphery is the only active part of an electrode and that in a bath it is only at the surface of the water that any appreciable amount of current enters the body. This will be all the more easily believed by anyone who has had a galvanic bath since the characteristic pricking sensation of the constant current is only felt, or most strongly felt, where the surface of the liquid touches the skin. Altogether it looks as if it would be necessary to modify many of our methods considerably if we are to get the best obtainable results in electro-therapy.

Dr. SIRERA SALSE (Barcelona) read a paper on Electro-therapy in the Treatment of Traumatism and demonstrated its value by giving an account of a series of control experiments on rabbits with microscopic examination.

Dr. BELLEMANIÈRE showed and explained the use of a special extensible electrode which he uses for the treatment of urethral stricture.

High-Frequency Currents.

Dr. DE NOBELE (Gaud) gave a discourse on the action of fulguration on tissues. In this the intense shower of sparks from the resonator of a very powerful high-frequency apparatus is directed on to the growth by means of a special electrode, in which carbonic acid gas from a cylinder is used to cool the spark and to prevent actual burning. He considers that malignant growths should be first removed as far as possible by the surgeon and fulguration applied very thoroughly to the base of the wound. In the course of the paper he produced evidence of the histological changes and the depth of action as well as the influence of the cooled electrode and the process of cicatrisation.

Dr. LIBOTTI (Brussels) gave evidence of the good effect of high-frequency currents in arterio-sclerosis.

Probably the most interesting paper on this subject was by Dr. BAUDEL on the Treatment of Neuritis by High Frequency and a very lively discussion followed, in which Dr. MOUTIER, Dr. ZANIETOWSKY, Dr. STEPANOF, and Dr. NOBELE took part.

Radio-diagnosis.

In this branch it is pleasing to note that though no one from this country took part our cousins, the Americans, were easily first as regards improvement in methods and general technique.

Dr. LESTER LEONARD (Philadelphia) gave an address on the Value of Practically Instantaneous Exposures in the Diagnosis of Disease in the Thorax and Abdomen. For this work he has a special new apparatus, invented by Snook of Philadelphia, which enables him to pass as much as 60 milliampères through the x ray tube. By this he has reduced the time of the normal exposure for the abdomen to about one-fifth of a second. In some of his radiographs the peristaltic waves of the stomach and intestine were very clearly shown. His thoracic plates were very rich in detail, showing the presence of, among other things, enlarged bronchial glands, which could not possibly be detected by any other means.

A very excellent series of skiagrams was also shown by Dr. HULST (Michigan). He has had constructed a huge static machine consisting of some 50 large plates arranged on a vertical shaft and driven by an electric motor, the two shafts being directly connected. This gives him a practically continuous current in contradistinction to the apparatus of Dr. Lester Leonard which gives a uni-directional pulsating current. Both these workers have eliminated inverse discharge from their circuits, which is an untold advantage. Dr. Hulst can get a good radiograph of the abdomen in one second, but he prefers to use a softer tube and gives a five-second exposure—a greater wealth of detail being obtained in this way.

The work of Professor WENCKEBACH (Groningen) deserves special mention. He is a strong believer in the stereoscopic method in that it gives real perspective and plasticity. Wenckebach is of the opinion that every consulting physician should train himself in x ray work as the time has now come when this can be no longer delayed. Also that the stereoscopic method shows much more detail and the true relationship of the various parts and is practically the only one that can be used for demonstration and the instruction of students. He had on view a whole room-full of most excellent stereo-radiographs. They were made on extra large plates and beautifully illuminated, so that with one of the several reflecting stereoscopes provided the series could be examined with a maximum of convenience and pleasure.

Papers on the Diagnosis of Renal Calculus were read by Dr. VAN DER GOOT (Gravenage) and Dr. HAENISCH (Hamburg). Short exposures, soft tubes, and large currents seem to be the methods now finding most favour.

The radiography of the vertebral column came in for much attention. A paper by Dr. GOCHT (Halle) had reference to the value of radiography in the diagnosis of spondylitis tuberculosa, in which the clinical symptoms give so little evidence of the extent of the mischief.

Dr. CONRAD (Antwerp) pleaded for more care in the examination of plates made of the lumbo-sacral region after accidents and gave instances where mere casual examination had failed to detect the presence of injury to the bones.

Dr. BERTOLOTTI (Turin) advocated sagittal skiagraphy of the cervical vertebræ when the question of caries arose. He showed the atrophy of bone and enlargement of the inter-vertebral foramen in such cases which were due to atrophy of the articular processes.

Professor BECLÈRD demonstrated the importance of examining the cupola of the diaphragm in disease of the liver, and Dr. KOHLER (Wiesbaden) described the method of radiographing the lower border of the liver, which at times gives useful information. He places the tube above with the anticathode at the level of the sixth dorsal vertebra, which brings out the border very sharply.

Dr. KIENBOCK (Vienna), as a result of some observations, was led to examine the heart in several cases after severe exertion. Instead of finding some dilatation he found a degree of temporary contraction. This was the more noticeable in the case of swimmers. His explanation is that of increased intra-thoracic pressure preventing the flow of venous blood to the heart.

of these being, no doubt, the foundation for its claim to tonic properties. We found present also as a provision against fermentation some salicylic acid but the amount was small and considerably less than that recommended to be permitted by the Departmental Committee on Preservatives. The flavour and the general characters of the beverage will no doubt appeal successfully to many persons but on the first point we have not formed a favourable opinion.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Dec. 10th, Mr. HENRY MORRIS, the President, being in the chair.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship, stating that at the recent examination 97 candidates presented themselves, of whom 37 were approved and 60 rejected.

In accordance with a report from the Court of Examiners it was resolved to issue Diplomas of Fellowship to 28 successful candidates.

It was resolved to issue diplomas in Dental Surgery to 33 successful candidates.

A report was received from the committee on the annual report of the Council. In accordance with the recommendations of that committee, it was resolved to adopt the following replies to the resolutions carried at the annual meeting. The first resolution was :—

> That this meeting thanks the Council for having for the first time in its history taken a poll of the Members of the College, but regrets that the Council found itself unable to abide by the result. This meeting also trusts that the Council will shortly take a further poll of the Fellows and Members on the question of the direct representation of Members, as requested by the last annual meeting.

The Council's reply was :—

> The Council regret that their views and those of the majority of the Members who replied to the circular addressed to them regarding the admission of women to examination for the diplomas of the College are not in accord. With regard to the suggestion that the Council should take a further poll of the Fellows and Members on the question of the direct representation of Members, the Council adhere to their decision as set forth in the last annual report.

The second resolution was :—

> That this meeting is of opinion that women when admitted to the diplomas of the College should have equal rights with men.

The reply was :—

> The Council have from the first signified their intention of proceeding under the Medical Act of 1876, whereby no woman admitted a Fellow or Member would be entitled to take any part in the government, management, or proceedings of the College. The Council see no reason for departing from the course which they decided upon after due and careful consideration.

The third resolution was :—

> That the President and Council of the Royal College of Surgeons be respectfully asked to use their moral influence to obtain some more sufficient title for those who have passed the examinations for the Conjoint Diploma, remembering the importance attached to degrees to the detriment of holders of the said diploma granted by this ancient corporation in conjunction with the Royal College of Physicians of London.

The Council's reply was :—

> The Council once more express the opinion that it is impracticable to obtain a legal right to the title of Doctor of Medicine for any person who does not hold the degree of M.D. The Council would refer those who supported the resolution to the last annual report for information as to the steps which they have been, and are, taking with a view to providing medical students of London with greater facilities for obtaining degrees in medicine.

Mr. W. G. Spencer was elected a member of the Court of Examiners.

Mr. Edmund Owen was appointed a member of the Court of the University of Liverpool for three years.

A report was received from the delegates of the Royal Colleges of Physicians and Surgeons appointed to consider a scheme for a system of conjoint examinations with the University of London.

A letter was read from the President reporting the proceedings of the General Medical Council at its recent session, and the best thanks of the Council were given to the President for his services as the representative of the College on the General Medical Council.

A letter was read from the Registrar of the General Medical Council inquiring by direction of that Council how far the College had given effect to the recommendation of that Council of June, 1907, "by requiring students to produce evidence of having received practical instruction in the administration of anæsthetics." It was resolved to send the following reply :—

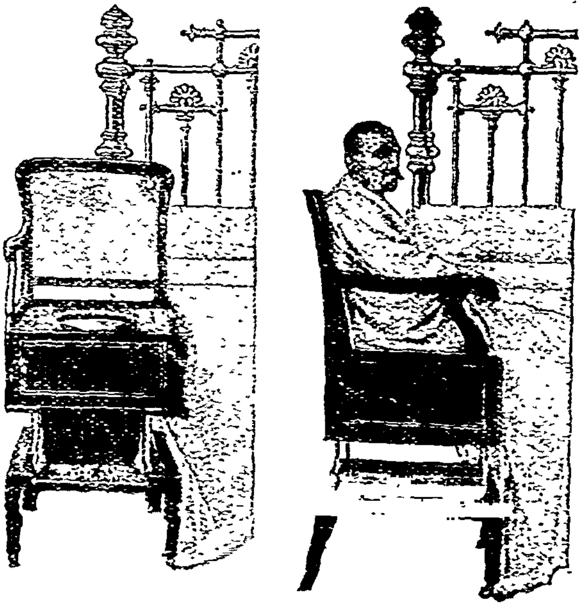
> That the General Medical Council be informed that the desirability of making practical instruction in the administration of anæsthetics a compulsory part of the medical curriculum was recognised by the Council of the Royal College of Surgeons of England in 1901, and that in December of that year, in conjunction with the Royal College of Physicians of London, a regulation was adopted requiring every candidate before admission to the Final Examination to produce a certificate of having received at a recognised medical school and hospital instruction in the administration of anæsthetics to the satisfaction of his teachers, and that, moreover, questions on the subject are from time to time put to candidates by the examiners of the College. That the Council trust that the General Medical Council will be successful in the present endeavour to induce other examining bodies to adopt a regulation which has long been in force at the English Royal Colleges of Physicians and Surgeons.

The PRESIDENT reported the delivery of the Bradshaw lecture by Sir W. Watson Cheyne, Bart., on Dec. 4th, the subject of the lecture being the Treatment of Wounds. The best thanks of the Council were given to Sir W. Watson Cheyne for his lecture and he was requested to publish it.

New Inventions.

A NEW RISING SEAT COMMODE.

IN attending a case recently in which the patient was so averse to the use of the bed pan that aperient medicines had to be constantly given, it occurred to me that if the commode in common use could be made adjustable to the height of *any* bed, the patient could with very little assistance shift himself on and off it with comparative ease, the difficulty of *lifting* a heavy patient back to bed from the ordinary commode being thus overcome. This suggestion of mine has been skilfully carried out by Messrs. J. and A. Carter, of 26, New Cavendish-street, W., and many other useful additional features added. The arms of this chair turn down, leaving the seat flush with the height of any bed, and a firm strong footboard is fitted, so that the patient can slide off either side of the bed on to the seat and occupy a natural position, or can sit on the commode with the legs remaining in bed. A false caned seat slides over the orifice when the commode is required for use as an ordinary chair. The mechanism of the rising seat is easily operated by nurse or attendant, by whom this commode will be found, I think, of considerable use.



H. W. ARMSTEAD, M.D. Lond., F.R.C.S. Eng.

Queensborough-terrace, Hyde Park, W.

head, two-thirds of the body, and the legs on both sides down to the knees. The state of her hands suggested that she had burned them in tearing off her clothing. The tongue was protruding and the condition of the lungs showed that death had been caused by suffocation in addition to the effect of the burns. There were no signs that the suffocation had been produced by external violence and the parts of the body burnt pointed to her clothing having caught fire when she was standing. There was no sign of outrage and nothing to suggest that any drug had been administered. The rest of the evidence in the case added very little to the jury's knowledge of the cause of the death of the deceased, as was shown by their verdict that she was suffocated or burned to death but that there was not sufficient evidence to say how she came by her burns. If, however, there was nothing either to point to foul play or to prove that an accident took place, there was enough to show that the mystery which still exists was one which demanded inquiry of the most complete nature possible. According to the evidence of the brothers at Lumb Farm, after they had gone to bed their sister did not follow their example but at some time or other in the night went out, locked the door, and pushed back the key under it, as she had done on previous occasions. This, if true, would negative the suggestion that she set herself accidentally alight in the house and ran out, or that she left it for a temporary purpose carrying a candle and matches, the former of which was found by a gate 44 yards from the house and the latter nine yards farther off in the pigsty close to the body of the deceased. There was a suggestion that paraffin had caused the rapid ignition of her clothing or of her hair on a night which, a witness said, was wet, misty, and windy, but although there was some evidence of her washing her hair occasionally with paraffin there was none that she had done so that evening and the paraffin lamp in the farmhouse had apparently not been lighted. There was no evidence that she was unhappy or that she had any particular male friend or any enemy, and her leaving the house for the night would not have been very unusual as sometimes she went over to Park Farm and slept there. There was evidence which pointed to the death having taken place soon after the brothers had gone to bed, as Nelson, the farmer mentioned above, and his daughter said in the witness-box that they had noticed a bright light in the direction of Lumb Farm when they went out to feed cattle before going to bed. Among the garments that the deceased was wearing a flannelette petticoat was mentioned. The balance of probability in view of the evidence given at the inquest points to an accident owing to the deceased going to an outhouse with a candle and matches, if the brothers were mistaken and if the key found by them had in fact fallen from a door closed but not locked. What actually took place must, however, almost necessarily remain a mystery, and the record of the subsequent proceedings occasioned by the futile first inquest will remain as a warning to coroners who endeavour to dispense with medical evidence. The proceedings which led to the second inquest were taken under Section 6 of the Coroner's Act 1887, which commences as follows:—

> Subsection (1). Where Her Majesty's High Court of Justice upon application made by or under the authority of the Attorney-General is satisfied either (*a*) That a coroner refuses or neglects to hold an inquest which ought to be held; or (*b*) where an inquest has been held by a coroner that by reason of fraud, rejection of evidence, irregularity of proceedings, insufficiency of inquiry or otherwise it is necessary or desirable, in the interests of justice, that another inquest should be held, the court may order an inquest to be held touching the said death, and may, if the court think it just, order the said coroner to pay such costs of, and incidental to, the application as to the court may seem just, and where an inquest has been already held may quash the inquisition on that inquest.

The two following subsections enable the court to order that a coroner other than the one against whom the application is made shall hold the inquest ordered and also directs that at such an inquest it shall not be necessary to view the body unless the court order otherwise. In the case under comment the court made no order as to costs, and the expense occasioned by two inquests instead of one and that of bringing about the holding of the second one will apparently have to be borne by the county in which the inquests took place. As county councils are sometimes stated to be responsible for a desire on the part of coroners to economise in the matter of the fees of medical witnesses, county councils as well as coroners may find the proceedings following the death of Elizabeth Whitaker instructive.

The Peculiar People and the Duties of Midwives.

An inquest was held recently at Canning Town on th body of Emily Sophia Ballard, a married woman and member of the sect known as the Peculiar People, who wa found upon the medical evidence to have died from puerpera septicæmia and peritonitis, a rider being added to the effec that the midwife should be dealt with under the Midwive Act. The coroner upon this directed the midwife not t practise until she heard from the central authority Mrs. Ballard, who had borne other children before, wa delivered on Nov. 22nd, being then under the care of registered midwife. According to her husband's evidence everything went well until Dec. 3rd when his wife becam very ill and he seems to have offered her medical assistanc which she absolutely refused. An elder of the sect was however, called in and on the following Sunday, Dec. 6th, prayer meeting was held on her behalf. On the next day Dec. 7th, she died. The midwife gave evidence that sh attended the deceased for six days only, and that if she ha thought that her patient's condition demanded the intervention of a medical man she would have taken it upo herself to call one in. No doubt the local supervising authority will take notice of the jury's expressed opinion, but, whatever it or the Central Midwives Board may decide after full inquiry into the facts, a midwife attending a patient who is of the Peculiar People will not have much power to avert serious results when complications occur. The duty imposed on her under the Midwives Act when certain specified complications arise is to "decline to attend alone" and to "advise that a registered medical practitioner be sent for." In the case commented upon it will be seen that the midwife, if her statement was correct, ceased to attend the case some days before the husband noticed that his wife was "very ill." With regard to the responsibility of the near relatives of the deceased in a case of this kind, it is not easy, or indeed possible, to convict them of manslaughter of a person who, being of full age and in possession of her usual faculties, resolutely declines to have medical assistance. Even the recommendation made by the midwife and her refusal to continue in charge of a case can hardly affect the matter when the death of the mother only has been the result. If the advice to call in a medical man were due to conditions in the newly born child demanding his assistance, no doubt evidence of the warning given by the midwife would aggravate the charge against the parent or parents, but, as all know, the punishment usually inflicted upon members of this strange and unreasonable sect in our courts of law is not very heavy and does not seem to deter them or their brethren from similar conduct upon other occasions.

The Poisoning Case at Antrim.

At the Ulster Assizes the trial recently took place of a woman named Elizabeth Kirkwood Doherty who was indicted for the murder of her husband. The case was opened by the Solicitor-General for Ireland who told the jury that he would satisfy them that no human hand but that of the prisoner was laid upon an egg which contained the poison from the moment when it was broken into a pan until it reached the deceased who ate it for his supper. The husband had died on the following morning, and a daughter of the couple, aged three years, died a week later, having apparently had strychnine administered to her in milk. This second death had been followed by the exhumation of the body of the man and the charge against his wife. The suggestion made by counsel for the defence was that the poison had fallen through the rafters of the kitchen from a loft above and so got into the egg. The husband appears to have expressed before he died the opinion that this had been the case, and counsel, in addressing the jury, laid stress upon his having done so. Presumably the jury were impressed by the possibility of the unusual accident described having happened, for the prisoner was found "Not guilty" and was discharged.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN IN SOMERSET.—At a meeting of the Somerset County Education Committee, held at Bridgwater last week, it was decided to appoint a full-time assistant medical inspector of schools who should have had a special training in ophthalmic work.

of all bread-winners—has undergone no improvement beyond those incidental to the very incomplete reforms accomplished in the housing of the people. The lethargy of successive governments was not due to lack of protest, for during the last half of the nineteenth century the case of the sweated was pleaded from many platforms and in not a few newspapers, amongst which THE LANCET took its stand. In later decades the realistic school of journalism, and the establishment of University and public school settlements in the East-end of London, perhaps, too, the slumming expeditions which became a fashionable hobby in the early "eighties," brought the actual conditions of home labour still more vividly before the public. In 1890 Lord DUNRAVEN'S Committee was appointed which, after hearing evidence from 291 witnesses drawn from many different trades and localities, recorded the opinion that the evils of sweating "can hardly be exaggerated." But although still more indignation was expressed at the "grinding of the faces of the poor" no direct legislation resulted and attention was again flagging in the matter when the *Daily News* in 1906 organised a vigorous propaganda by means of an "Exhibition of Sweated Industries." This idea was borrowed from Berlin, where similar exhibitions had been held with success in 1904 and 1906, the first of which had been followed by a smaller exhibition organised by the Rev. J. E. WATTS-DITCHFIELD at Bethnal Green. It was the attention aroused by his venture that encouraged the *Daily News* to embark on its more ambitious enterprise two years later. We need say little about this exhibition, as doubtless many of our readers visited it and others will remember that we published an account of it which we received from our Sanitary Commissioner, but we may recall that its main purpose was to show to the public typical home workers in different sweated industries plying their trades under conditions representing as closely as possible their actual home surroundings. A carefully compiled handbook gave full information concerning the wages paid for the work which was exhibited and the number of hours of labour in the week which its production entailed. This exhibition afforded so impressive an object lesson that to it may be given a large share of credit in the appointment by the Government in 1907 of a Select Committee "to consider and report upon the conditions of labour in trades in which home work is prevalent, and the proposals including those for the establishment of wages boards and the licensing of work places which have been made for the remedy of existing abuses." This committee took a large body of expert evidence and reported it without comment, recommending the appointment of another committee in the next session of Parliament. The recommendation was carried out and the report of the 1908 committee is contained in the Blue-book which was issued during the summer recess and with which we are concerned at present.

The bulk of the Blue-book is made up of the minutes of evidence which was given by manufacturers, home workers at different trades, factory inspectors, social workers amongst the poor, and others having special knowledge of the question. Medicine had no direct representative, although the 1907 committee, which had almost the same constitution as that of 1908, heard the evidence of Dr. R. DUDFIELD, medical officer of health of Paddington, on the sanitary issues involved and many of the witnesses answered questions on cognate points. On the whole, however, the sanitary side of the problem was unduly subordinated to the industrial. If a national problem ever had to be faced in which these two factors were inextricably blended it is surely that presented by the home workers, for their physical and economic welfare are strictly interdependent. The somewhat one-sided view of the committee is shown in these lines from its report which prefaces the evidence: "It is doubtful whether there is any more important condition of individual and general well-being than the possibility of obtaining an income sufficient to enable those who earn it to secure at any rate the necessities of life." This is a sound enough maxim, for it is quite obvious that any legislation insuring a regular and proper "living wage" to a large body of workers must react favourably upon the health of the community. Better nutrition and better clothes for mothers and children will result in increased resistance to diseases amongst a class which at present forms a focus of varied infection. But the matter does not end with increasing by law the earnings of home-workers. The responsibility of the State is no less concerned in safeguarding their "individual and general well-being" by seeing to the healthfulness of their environment. Sanitary conditions of life should be the first condition of labour in the home no less than in the factory and should not be dependent upon the fruits of the labour. But this brings the argument round again to its economic side, and the problem of ways and means is hardly suited for discussion by a medical journal which may, however, properly record the chief of the committee's conclusions, some of which have important bearings upon the public health. In the first place it has proved by full evidence a matter of common knowledge "that the earnings of a large number of people—mainly women who work in their homes—are so small as alone to be insufficient to sustain life in the most meagre manner, even when they toil for extremely long hours," and it is also satisfied that sweating exists at present in such a degree as to call urgently for the interference of Parliament, a verdict that can be disputed by no one who reads the evidence on which it is based. We need only quote that given by a home worker, "Miss G."—admittedly the worst case examined by the committee—who stated that she worked from 6 in the morning till 12 at night at shirt finishing to earn about 5*s.* 6*d.* a week, and summed up her physical condition in the remark, "I can get a little bit of bread, and that is all we do get." We may add that her *bona fides* and that of all the industrial witnesses were established on good authority. Turning to the committee's report, we find that after giving a classification of home workers it proceeds to consider at some length the reasons of their scanty earnings. This section endorses the opinion expressed by the Labour Commission in 1894. "In the absence of organisation and in the face of the unlimited competition for the cheaper and less skilled kind of sempstress and similar work, there seems to be little to prevent wages from sinking to the point at which, in the words of one witness, 'it is easier to starve without

Paisley and Leith, to 16·7 in Greenock and 19·5 in Dundee. The 536 deaths in the eight towns showed a decline of 47 from the number returned in the previous week, and included 50 which were referred to the principal epidemic diseases, against numbers declining from 68 to 53 in the four preceding weeks; of these 50 deaths, 19 resulted from whooping-cough, 15 from diarrhœa, seven from diphtheria, six from scarlet fever, and three from "fever," but not one either from measles or small-pox. These 50 deaths were equal to an annual rate of 1·4 per 1000, exceeding by 0·1 the mean rate during the week from the same diseases in the 76 English towns. The 19 fatal cases of whooping-cough in the eight Scotch towns showed a further increase upon the numbers returned in recent weeks, and included 12 in Glasgow and three both in Dundee and Aberdeen. The deaths attributed to diarrhœa, which had been 25 and 18 in the two preceding weeks, further declined last week to 15, and were fewer than in any week since the beginning of July; 12 occurred in Glasgow and two in Dundee. Of the seven fatal cases of diphtheria five were returned in Glasgow and two in Dundee. The six deaths from scarlet fever, including three in Glasgow, corresponded with the number in the previous week. The three deaths referred to "fever" occurred in Glasgow; two were certified as cerebro-spinal fever and one as enteric. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 136, 133, and 113 in the three preceding weeks, rose again to 115 in the week under notice, but were 47 below the number returned in these towns in the corresponding week of last year. The causes of 13, or 2·4 per cent., of the deaths registered during the week in the eight towns were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 1·1 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 24·2, 22·2, and 23·8 per 1000 in the three preceding weeks, declined to 21·9 in the week ending Dec. 12th. During the first eleven weeks of the current quarter the death-rate in the city averaged 21·2 per 1000, whereas the mean rate during the same period did not exceed 14·1 in London and 13·9 in Edinburgh. The 166 deaths of Dublin residents during the week under notice showed a decline of 14 from the number returned in the previous week, and included 13 which were referred to the principal epidemic diseases, against 11 and 12 in the two preceding weeks. These 13 deaths were equal to an annual rate of 1·7 per 1000; the rate from these diseases in the same week did not exceed 1·1 in London and 0·3 in Edinburgh. Of the 13 deaths from these epidemic diseases in Dublin last week, seven resulted from measles, three from whooping-cough, and one each from diphtheria, "fever," and diarrhœa, but not one either from scarlet fever or small-pox. The seven fatal cases of measles showed a further increase upon recent weekly numbers, and the three of whooping-cough also showed an increase. The 166 deaths from all causes during the week included 34 of infants under one year of age and 47 of persons aged upwards of 60 years; both these numbers were below those returned in the previous week. Two inquest cases and two deaths from violence were registered during the week, and 67, or 40·4 per cent., of the deaths occurred in public institutions. The causes of four, or 2·4 per cent., of the deaths in Dublin last week were not certified; the proportion of uncertified causes of death in Edinburgh last week was equal to 1·9 per cent., while in London the causes of all the 1311 deaths were duly certified.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1908.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 9·2 per 1000 of the population, estimated at 4,795,757 persons in the middle of the year; in the three preceding months the rates were 6·3, 8·6, and 9·2 per 1000 respectively. The lowest rates last mo were recorded in Kensington, Hammersmith, St. Mar bone, Hampstead, the City of London, and Lambeth; the highest rates in Holborn, Shoreditch, Bethnal Gre Stepney, Poplar, and Battersea. The prevalence scarlet fever showed a slight decline from that corded in either of the two preceding months; disease was proportionally most prevalent in the of Westminster, Stoke Newington, Hackney, Shoredit Bethnal Green, Poplar, and Battersea. The Metropoli Asylums Hospitals contained 3787 scarlet fever patie at the end of last month, against 2807, 3431, and 3776 the end of the three preceding months; the wee admissions averaged 477, against 365, 506, and 493 in three preceding months. Diphtheria was more preval during November than in any preceding month of this ye among the various metropolitan boroughs the greatest portional prevalence was recorded in Fulham, Shoredit Stepney, Battersea, Lewisham, and Woolwich. The num of diphtheria patients remaining under treatment in Metropolitan Asylums Hospitals at the end of last mo was 1228, against 843, 953, and 1118 at the end of three preceding months; the weekly admissions averag 158, against 110, 128, and 158 in the three preced months. Enteric fever, which had shown a continuou increasing prevalence in each month since June, was ag considerably in excess last month; this disease was prop tionally most prevalent in Holborn, Finsbury, Shoredit Bethnal Green, and Bermondsey. There were 184 ente fever patients under treatment in the metropolitan asylu hospitals at the end of last month, against 69, 95, and at the end of the three preceding months; the wee admissions averaged 29, against 12, 18, and 24 in the th preceding months. The 18 cases of puerperal fever notif during the month included three which belonged Southwark and two each to Kensington, Fulham, a Lambeth. Of the six cases notified as cerebro-spinal men gitis three belonged to Wandsworth, and one each Islington, Stepney, and Lambeth.

The mortality statistics in the table relate to the deaths persons actually belonging to the various boroughs, the deat occurring in institutions having been distributed among t several boroughs in which the deceased persons had p viously resided. During the four weeks ending Nov. 28th t deaths of 5365 persons belonging to London were register equal to an annual rate of 14·6 per 1000; in the three p ceding months the rates had been 12·9, 12·8, and 12·3 1000. Among the several boroughs the death-rates l month ranged from 7·2 in Hampstead, 11·3 in Woolwi 11·6 in Battersea, 11·8 in Stoke Newington, 11·9 Greenwich, and 12·1 in Wandsworth, to 17·5 in Holbo and in Stepney, 18·2 in Shoreditch, 18·8 in Southwa 19·3 in Bermondsey, 20·9 in Finsbury, and 21·7 in t City of London. The 5365 deaths from all caus included 457 which were referred to the principal e demic diseases; of these, 123 resulted from measl 38 from scarlet fever, 82 from diphtheria, 31 fr whooping-cough, 39 from enteric fever, and 144 fr diarrhœa, but not any from small-pox, from typhus, from ill-defined pyrexia. No death from any of the diseases was recorded last month in the City of Londo among the metropolitan boroughs they caused the lowest deat rates in Hampstead, Stoke Newington, Wandsworth, a Camberwell; and the highest rates in Holborn, Finsbur Bethnal Green, Stepney, Bermondsey, and Lewishar The 123 deaths from measles were equal to the avera number in the corresponding period of the five precedi years; the greatest proportional mortality from this disea was recorded in Chelsea, St. Marylebone, Finsbury, Bethn Green, Stepney, Bermondsey, and Lewisham. The 38 fat cases of scarlet fever were slightly fewer than the correct average number; this disease was proportionally most fat in Paddington, Hackney, Shoreditch, Bethnal Gree Stepney, and Woolwich. The 82 deaths from diphther were 19 in excess of the average number in the correspondin weeks of the five preceding years; the highest death-rates from this disease last month were recorded in Fulham, Stepney, Poplar, Southwark, Lambeth, Lewisham, and Woolwich. The 31 fatal cases of whooping-cough were 24 fewer than the corrected average number; this disease was proportionally most fatal in Paddington, Fulham, Islington, Shoreditch, Bethnal Green, Stepney, and Woolwich.

Arras, Angers, Besançon, Caen, Clermont, Dijon, Grenoble, Limoges, Poitiers, Reims, Rouen, and Tours. In the former students can study for the whole 16 terms of the curriculum, in the latter only for the 12 early terms, and in both cases the final examination must be taken before a faculty. There is a dean (*doyen*) at the head of each faculty who is appointed by the Minister of Public Instruction for a period of three years, and is chosen from the titular professors. The professoriate is divided into two classes—titular professors and *agrégés*. The latter are appointed for stated periods, usually nine years, but the period can be extended by the Minister. They assist in the examinations, replace the professors when they are absent, and give courses supplementary to those of the professors. There are two varieties of the diploma of Doctor of Medicine in France—that of a university and that of the State. The university diploma is open to foreigners; it is purely academic and is only of value as a scientific qualification. It does not confer the right to practise or any other of the privileges of the State diploma. Certain regulations must be conformed to, certain examinations taken, and fees paid amounting to 1400 francs in order to obtain this diploma. For the State diploma the curriculum is four years, divided into 16 terms. Various examinations have to be passed, a thesis written on some subject, and fees of 1390 francs paid. This part also contains information regarding the military, naval, and colonial medical services and the various associations of students both in Paris and elsewhere.

The second part is devoted to the University of Paris, to the hospitals and institutions in that city, and to the various medical societies. The Faculty of Medicine of the University of Paris was founded in 1808 in succession to the Ecole de Santé, which was itself the successor of the old Faculty of Medicine suppressed in 1793 at the same time as the College of Surgery. Full information is given of the various courses of lectures to be given during the academic year 1908–09 and of the special courses to be held during the vacations. The various hospitals of Paris are described, the staff of each is given, and the courses of instruction and the clinical facilities afforded by each are set forth. A special chapter is devoted to the Pasteur Institute and Hospital. The institute is described and the nature of the work carried on there is briefly outlined. It is of interest to learn that since 1889 more than 1000 persons have attended the lectures and practical courses of microbiological technique, while nearly an equal number have attended the lectures only, showing what an important part the institute has played as an educational body as well as a home of research. A special chapter is devoted to the consideration of the preliminary scientific education of the medical student who has to produce a certificate of having passed the P.C.N. (i.e., physics, chemistry, and natural history). This preliminary year is under the control of the Faculty of Science. The four dental schools in Paris are next described. The dental course extends over three years and the examinations are carried out by the Faculty of Medicine. The fees vary from 1000 to 1500 francs and the examination fees amount to 250 francs. The second part is brought to a close by an interesting account of the various medical societies. The constitution of the well-known Academy of Medicine is detailed and the prizes offered by it, amounting to nearly 60, are enumerated.

The third part is concerned chiefly with the provincial universities and schools, and gives the various courses of lectures and practical work afforded in them. An interesting appendix to it gives brief details of foreign universities in which the French language is employed, including the Belgian universities of Brussels, Ghent, Liége, and Louvain, the Universities of Geneva, Lausanne, Bucharest, and Jassy, and the Faculties of Medicine of the Laval University in Quebec and Montreal. The fourth and concluding part is specially addressed to the practitioner. It opens with some general advice to those newly qualified concerning registration, starting in practice, professional secrecy, the signing of certificates, responsibility, and the many difficult problems with which the professional man may be called upon to deal. The various laws, rules, and regulations concerning medical practice are then summarised, including special laws dealing with the practice of pharmacy and the supply of therapeutic serums and similar products. The various societies for professional assistance and protection are next described, with their objects and aims. The concluding section is devoted to the thermal stations and mineral springs of France and gives useful accounts of the chief features of these waters and the indications for their use. *Le Progrès Medical* is to be congratulated upon this very useful production; it should be of great value to all people in this country who are interested in medical education in France and to those who propose to pursue post-graduate or vacation courses of study in Paris or at any other of the great medical centres in France.

Annotations.

"Ne quid nimis."

NATIONAL HEALTH.

ON Dec. 11th the third annual meeting of the National League for Physical Education and Improvement was held in the Jerusalem Chamber adjoining the south side of Westminster Abbey under the presidency of the Bishop of Ripon. His lordship, in moving the adoption of the report and the accounts, said that the object of the league was to make people as physically "fit" as possible. It had lately been realised that the mind could not be properly educated unless the body was so too. By means of proper care and forethought much infantile mortality might be prevented. The Lord Mayor, who seconded the motion, said that unless they began with the child they would never teach the alphabet of regeneration. A pure milk supply was of the most vital importance. He was going to do all he could to make his year of office a children's year. The report and accounts were adopted, the former containing a recommendation that Poor-law authorities should be granted powers to acquire farms in Canada and other suitable sites in the empire. The Archbishop of Canterbury said that they could not separate man into two parts. Both the physical and the spiritual sides must be dealt with. It was often asked why the legislature did not do something, but the legislature had done its part, it was owing to the apathy of the public that so little had been done. The meeting then terminated. For our part we think that the problems which the league has set itself to solve are among the most

The 39 deaths referred to enteric fever showed a slight decline from the average number in the corresponding period of the five preceding years; the highest death-rates from this disease last month were recorded in Chelsea, Islington, Holborn, Finsbury, Bethnal Green, Stepney, Bermondsey, and Deptford. The 144 fatal cases of diarrhœa were 35 in excess of the corrected average number; this disease showed the greatest proportional mortality in Holborn, Finsbury, Southwark, Bermondsey, Deptford, and Lewisham. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 9·5 per cent. above the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 128 per 1000. The lowest rates of infant mortality last month were recorded in St. Marylebone, Hampstead, Stoke Newington, Holborn, Bethnal Green, and Woolwich; and the highest rates in St. Pancras, Finsbury, the City of London, Southwark, Bermondsey, Camberwell, Deptford, and Lewisham.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: C. J. E. Cock to the *Queen*, on recommissioning; and C. R. Sheward to the *Majestic*. Surgeons: W. H. Edgar to the *Vengeance*; G. A. Bradshaw to the *Magnificent*; G. L. Buckeridge to the *Kinsha*; and H. M. Braithwaite to Portland Hospital.

ROYAL ARMY MEDICAL CORPS.

Captain Henry J. McGrigor retires, receiving a gratuity (dated Dec. 16th, 1908). The undermentioned officers are seconded for service under the Colonial Office (dated Nov. 27th, 1908):—Captain William M. B. Sparkes, Lieutenant Harold T. Treves, and Lieutenant Gerald J. Keane.

TERRITORIAL FORCE.

Unattached List for the Territorial Force.—The undermentioned officer, from the disbanded 1st Flintshire Royal Engineers (Volunteers), is appointed to the Unattached List, with rank and precedence as in the Voluntter Force (dated April 1st, 1908):—Surgeon-Captain George Osborne Morgan Lunt.

Royal Field Artillery.

1st West Riding Brigade: The undermentioned officers from the 1st West Riding of Yorkshire Royal Garrison Artillery (Volunteers) are appointed to the brigade, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Captain Arthur Longley Whitehead and Surgeon-Captain John Nightingale.

Infantry.

7th Battalion, The Northumberland Fusiliers: Surgeon-Lieutenant Charles G. Maclagan resigns his commission (dated Oct. 1st, 1908).

Royal Army Medical Corps.

For attachment to Units other than Medical Units:—Captain Frederick Newman Grinling from the 1st Northumbrian Field Ambulance Royal Army Medical Corps to be Captain (dated Oct. 20th, 1908). James McHoul to be Lieutenant (dated Oct. 19th, 1908). The undermentioned officers from the 1st Battalion, The Herefordshire Regiment, are appointed Captain and Lieutenant respectively (dated Oct. 15th, 1908):—Surgeon-Captain James Neil Macmullan and Surgeon-Lieutenant Arthur Llewellyn Baldwin Green. Surgeon-Captain James Aitken, from the 4th Battalion, The Essex Regiment, to be Captain (dated April 1st, 1908). Captain (Honorary Captain in the Army) George G. Oakley, from the Yorkshire Mounted Brigade Field Ambulance, to be Major, with precedence next below Major William K. Clayton (dated April 1st, 1908). Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel Duncan Stewart, from the 4th Battalion, The Northumberland Fusiliers, to be Major with the honorary rank of Surgeon-Lieutenant-Colonel, with precedence from June 4th, 1902 (dated April 1st, 1908). Surgeon-Lieutenant James Graham Miller, from the 4th Battalion, The Northumberland Fusiliers, to be Lieutenant (dated April 1st, 1908).

2nd Southern General Hospital: James Paul Bush, C M G (late Surgeon-Lieutenant, 1st (City of Bristol) Volunteer Battalion, The Gloucestershire Regiment), to be Lieutenant-Colonel (dated April 1st, 1908). Arthur Launcelot Flemming to be Major (dated Nov. 7th, 1908). Charles Ferrier Walters to be Quartermaster, with the honorary rank of Lieutenant (dated Nov. 7th, 1908).

East Lancashire Division: Honorary Colonel Wa Whitehead, from the Western Command Manchester C panies Royal Army Medical Corps (Volunteers), is appoi to the Honorary Colonelcy, with precedence as in the Vol teers (dated April 1st, 1908).

Welsh Border Mounted Brigade Field Ambulance: S geon-Lieutenant George Jubb, from the 6th Battalion, T Highland Light Infantry, to be Lieutenant (dated July 1 1908).

1st West Lancashire Field Ambulance: Lieutenant-Colo Frederick Joseph Knowles, Royal Army Medical Corps, Ter torial Force, to be Lieutenant-Colonel (dated April 1st, 190 The undermentioned officers from the Volunteer Force a appointed to the unit, with precedence as in the Volunte Force (dated April 1st, 1908):—Surgeon-Captain Davi Smart, from the 2nd Volunteer Battalion, The King's (Liver pool Regiment), to be Captain. Surgeon-Captain Archibal Gordon Gullan from the 8th (Scottish) Volunteer Battalion The King's (Liverpool Regiment) to be Captain. Lieutenant Creighton Hutchinson Lindsay from the Western Command, Manchester Companies, Royal Army Medical Corps (Volunteers), to be Lieutenant.

2nd West Lancashire Field Ambulance: Lieutenant-Colonel Thomas Moore Dawson, Royal Army Medical Corps, Territorial Force, to be Lieutenant-Colonel (dated April 1st, 1908). Major Thomas Stevenson, Royal Army Medical Corps, Territorial Force, to be Major (dated April 1st, 1908) Surgeon-Major John Joseph O'Hagan, from the 5th Volunteer Battalion, The King's (Liverpool Regiment), to be Major, with precedence as in the Volunteer Force (dated April 1st, 1908).

3rd West Lancashire Field Ambulance: Captain Elisha H. Monks, Royal Army Medical Corps, Territorial Force, to be Captain (dated April 1st, 1908). The undermentioned officers from the Volunteer Force are appointed to the unit with rank and precedence as in the Volunteers (dated April 1st, 1908):—Major William Baron Cockill, from Lancaster and Border Bearer Company, Royal Army Medical Corps (Volunteers); Captain Claude William Scott Saberton, from the Western Command, Manchester Companies, Royal Army Medical Corps (Volunteers); Captain Henry Dodgson, from the Lancaster and Border Bearer Company Royal Army Medical Corps (Volunteers).

VOLUNTEER CORPS.

Royal Garrison Artillery (*Volunteers*): 3rd Kent (Royal Arsenal): The undermentioned officers resign their commissions (dated March 31st, 1908):—Surgeon-Lieutenant Bernard Hudson and Surgeon-Lieutenant Henry S. Desprez. 1st Norfolk: Surgeon-Captain Harold M. Evans resigns hi commission (dated March 31st, 1908).

Rifle: 2nd Volunteer Battalion, The Duke of Edinburgh' (Wiltshire Regiment): Honorary Assistant Surgeon Charle W. Pitt resigns his commission (dated March 31st, 1908).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Scottish Command, Edinburgh Company: The resignation of his commission by Captain David Waterston which appeared in the *London Gazette* of Dec. 8th, 1908, is cancelled.

The undermentioned officer, not having signified his wish to join the Territorial Force, is struck off the strength of the battalion:—2nd (Prince of Wales) Volunteer Battalion, The Devonshire Regiment: Surgeon-Lieutenant Peter George Moran (dated Dec. 16th, 1908).

SHELL-FISH AND ENTERIC FEVER.

The General Officer Commanding the South-Western Defence and Plymouth Garrison has recently issued the following order:—*The origin of a recent case of enteric fever in a soldier having been attributed to eating shell-fish, the troops are warned against the danger of eating such fish, even when cooked.*

stimulate women to increased readiness to undertake work in branches of public service in which the coöperation of women is specially required and would foster their consciousness of citizenship.

CHRISTMAS CHEER PSYCHOLOGICALLY AND PHYSIOLOGICALLY CONSIDERED.

WHEN persons determine to make a season festive they as a rule pay little heed to the teachings of physiology about the evils of excess or to what chemistry may have to say in regard to the composition of the good things which they mean to enjoy. Undue indulgence, however, brings at length a convincing proof of the physiological machine having been overtaxed in the shape of various unpleasant symptoms eloquent of the action of toxic agents. If, in short, the body cannot deal with the amount of food administered to it part of that food becomes more or less a poison. Nevertheless, there can be no doubt that when a person is situated in circumstances which tend to make him happy his digestive powers are stimulated and increased. Christmas is a time of good cheer and therefore is a season which should be calculated to help those psychical influences which are an important factor in the great processes of alimentation. The meal partaken in the house of mourning has a much less chance of actually ministering to the needs of the body than has a meal partaken in the house of joy. This is an interesting example of the effect of mental influence to which to some extent the digestive functions are subservient and which is constantly in evidence. No man unless his instincts are more brutal than refined sits down for choice to a meal alone or drinks his wine in solitary silence. He regards his food not merely as a bodily necessity but as something also that can be artistic and elegant, and he is led to seek an environment during a repast which is mentally as well as physically congenial, and in doing so his digestion is facilitated. To partake of food under the influences of pleasurable refinements is an excellent physiological proceeding. There is nothing physically or physiologically immoral therefore in the cheerful feast; it is not a sin to enjoy food or to secure the partaking of it under agreeable surroundings. On the contrary, such procedure is perfectly compatible with physiological law, and it is not at the risk of offending physiology to wish those persons a merry Christmas who can enjoy creature comforts wisely, who know the evils of excess, and who act accordingly.

FRESH AIR IN THE TREATMENT OF PNEUMONIA.

IN the *American Journal of the Medical Sciences* for November Dr. G. W. Norris has reported good results from fresh air in the treatment of pneumonia at the Philadelphia General Hospital, where the type of the disease is of unusual severity. Most of the patients are advanced in years and often suffer from arterio-sclerosis and chronic nephritis, and a large number of tramps and drunkards is also comprised. As might be expected, the mortality was high—53 per cent. before adoption of this treatment and 43 per cent. after its adoption. If the patients who died within the first 24 hours—i.e., were moribund on admission—be deducted the latter mortality was 38 per cent. Apart from the constantly open doors and windows no other innovation was made in the previous treatment. Dr. Norris observes that the use of alcohol is steadily falling more and more into disfavour, and justly so, since it does more to relax the vaso-motor system than to stimulate the heart, and that it has been shown by the researches of Paessler and Rolly that death in pneumonia is due to failure of this system. He admits, however, that habitual drunkards are often benefited by a reasonable amount of alcohol. Sponging with cold water was used frequently and with good results, not so much for the purpose of reducing the temperature, which it does satisfactorily, but with a view to increase the tone of the vaso-motor system, for which purpose it seemed to be the most useful remedy. The value of fresh air is illustrated by the case of a big negro on the third day of an attack of pneumonia. In the general medical ward he was restless, feverish, and panting, the typical picture of the anguish so often seen in these cases. An hour later he was seen in the pneumonia ward to which he had been transferred. It was a cold March day and the doors and windows were wide open, so that a constant current of fresh cold air blew over the beds. The patient greeted Dr. Norris with a smile and said, "I feel like another man here." It certainly requires, as Dr. Norris observes, some courage and persuasive power over the patient's relatives to adopt this treatment but once tried he is convinced that the practitioner will not abandon it. We may add that good results have been reported from the open-air treatment of pneumonia by another American writer, Dr. Northrup, and also by Dr. G. E. Rennie in the Prince Alfred Hospital, Sydney. The last writer places his patients at once on the balcony or verandah of the hospital, where they are kept night and day. A screen is kept round the head of the bed to prevent the cold air from blowing directly on the patient. This seems to us a necessary precaution, for however valuable fresh air may be few will regard a draught as desirable in pneumonia. Dr. Rennie at first hesitated to adopt this method when complications such as bronchitis were present but even then he found it equally successful. In one case which he reports, a girl, aged 12 years, had marked dyspnœa and cyanosis and a temperature of nearly 104° F., a rapid weak pulse, and extensive labial herpes. There were signs of consolidation at both bases. She was inclined to be delirious and had not slept for two nights. She was placed on the balcony with a screen round her head. On the first night she slept well and improved much.

MORTALITY OF THE MEDICAL PROFESSION IN GERMANY.

A CORRESPONDENT writes: "Investigation into the mortality of the medical profession in Germany has been published[1] by Mr. A. Böhme, an actuary in Leipsic. He emphasises the fact that the oft-quoted mortality given by Caspar in 1835 was considerably too high, owing to an erroneous method of calculation. In 1886 the Gotha Lebensversicherungsbank published an investigation into 1058 deaths of medical men, a larger number than had been collected up to that time, and sufficient to give trustworthy results at least as to the main features. Alongside of this the author places Geisser's investigations on the medical men of Saxony and Weinberg's on those of Wurtemberg, which he examines critically. Among the results which emerge from his investigation it will be found that in all the figures there is an excess of mortality at the time of entrance into the profession, continuing for some five years thereafter in a decided degree, whilst the lowest mortality is found almost as late as the middle of the thirties. Radestock (who continued Geisser's work) suggests as the cause of this not merely the influence of hereditary disease and of acquired defects (e.g., alcoholism), but also the fact that the younger practitioner has not developed in his system the necessary proportion of alexins and antitoxins which contact with infective disease has produced in older physicians. The figures in each case give a mortality among medical men in evidence of tubercle; and 3 were discharged in whom there was undoubted evidence of tubercle—viz., one case of phthisis advanced to cavitation and two patients suffering from tubercular peritonitis, having masses easily felt in the abdomen. Of 7 cases where tubercle was suspected one positive reaction occurred (the diagnosis resting between sarcoma and tubercle); tubercle was found at the operation. Of the remaining six, the diagnosis resting between empyema and tubercle, all failed to react, and were operated upon and found to be empyemata. Two died later and no tubercle was found at the post-mortem examination.

---

[1] Zeitschrift fur Versicherungs-Wissenschaft, 1908, p. 652.

Two cases where the reaction was so indefinite (with 1 per cent. solution) that it was queried positive were found at the necropsy to be tubercle. These I have not included. It will be seen that in every case where a positive reaction was obtained tubercle was either found post mortem or definite clinical signs were evident. Three inaccuracies out of 45 cases occurred, but these were of the negative order. The patients submitted to the test were all under the care of the senior physicians, to whom I am indebted for the publication.

I am, Sir, yours faithfully,
HENLEY H. MOYLE.

East London Hospital for Children, Shadwell, E.,
Nov. 28th, 1908.

EPSOM ASYLUMS.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 5th is a short comment on the public meeting held in Epsom to protest against the walking parties from the lunatic asylums of the London County Council. As your remarks are likely, I think, to give a wrong impression as to the feeling in this locality on the question of the exercise of the lunatics in public, and also as to the object and result of the meeting, I hope you will give publication to these remarks. There were several motions before the meeting in addition to the one asking the London County Council to put a stop to "the practice of walking parties outside the asylum grounds" which you allude to, and one of the most important was the one asking the London County Council to direct attention to the escapes of lunatics. The result of the meeting was that the motions were passed and not lost by a large majority as you state. There were no direct attacks made on the medical superintendents as such, though, of course, the administration which permitted the walking parties and the escapes was adversely criticised, but the "attacks," if they can be called such, were directed against the asylums committee as a whole. As regards "the improvement in the mental state of the lunatics likely to be derived from the change of air and scene" there is some divergence of opinion amongst the medical superintendents of the asylums in this district as regards change of scene, for the medical superintendent of one of the asylums here does not permit the lunatics to exercise outside the grounds of the asylum he is in charge of, and his results are as good as the results of those who permit the walking parties outside the asylum grounds.

As was pointed out at the public meeting, the grounds of the asylums near here are extensive and give ample room for exercise, but no doubt popular opinion would be pacified if the asylums committee were only to allow small parties of selected patients with adequate escort to walk the public roads, and also if the asylum authorities take more active measures as regards escapes. As a result of the meeting a committee is to wait upon the Prime Minister, the Home Secretary, and the Lunacy Commissioners if found necessary.

I am, Sir, yours faithfully,
HORTON.

Dec. 8th, 1908.

A SERUM TREATMENT OF CARCINOMA IN MICE.

To the Editor of THE LANCET.

SIR,—You were good enough to verify by a note to my letter published in THE LANCET of Nov. 28th a quotation from a letter written to me by Dr. Borrel on Nov. 12th last, in which he said that he had done "nothing resembling" my experiments with sera upon carcinoma in mice. Dr. Blair Bell has stated that I had repeated Dr. Borrel's experiments. I have shown conclusively that I did nothing of the kind. He stated that I was self-invited to the Liverpool Medical Institution. I was not. In spite of this, in his letter to you published on Dec. 12th Dr. Bell attempts to maintain his original position, although he uses vague words of apology.

I am, Sir, yours faithfully,
CHARLES WALKER.

Cancer Research Laboratory, University of Liverpool
Dec. 12th, 1908.

THE CAUSE AND PREVENTION OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—In the discussion on "The Cause and Prevention of Dental Caries," which has been published in recent numbers of THE LANCET, it has been assumed that extreme frequency in the occurrence of dental caries is a purely modern phenomenon which most writers attribute to "modern dietetics" or "the changes the food of man has undergone during the last few centuries."

I would like to call attention to the fact that 5000 years ago, in the time of the Pyramid builders, dental caries and alveolar abscesses were at least as common amongst the adult aristocracy of Egypt as they are in Europe to-day, although dental caries was rare among the people of lower social status and almost unknown in children. Among several thousand children found in ancient Egyptian graves I have seen only three instances of caries in deciduous teeth.

These facts, I think, support the general conclusions to which the discussion has pointed.

I am, Sir, yours faithfully,
G. ELLIOT SMITH.

Cairo, Dec. 7th, 1908.

THE USE AND ABUSE OF ALCOHOL.

To the Editor of THE LANCET.

SIR,—Last night I attended a meeting of the Unite Services Medical Society, held at the Royal Army Medica College, when a most interesting and instructive discussio took place on the use and abuse of alcohol. The questio was raised as to whether the total abstaining races, such a the Hindoos, the Persians, and the Fellaheen of Egypt showed any evidence of being more moral or progressiv than the races that take alcohol, and it was also pointed ou that all the progressive races, including the Japanese, take i The total abstainers present did not attempt to answer th point, but it would be interesting if some of them could d so in your columns. Incidentally, they might also try t explain why the total abstainers have practically neve produced great admirals, generals, or statesmen.

I am, Sir, yours faithfully,
H. N. ROBSON.

Junior Constitutional Club, Piccadilly, W., Dec. 11th, 1908.

THE STERILISATION OF POTABLE WATERS BY MEANS OF CALCIUM HYPOCHLORITE.

To the Editor of THE LANCET.

SIR,—Your correspondents, referring to my brief co tribution to your journal of Nov. 28th, overlooked the mo essential point to which I directed attention—viz., that waters free from suspended matter and of fair organic purity almost infinitesimal amount of chlorine suffices for practic sterilisation. Experiments now being conducted on a larg scale indicate that the same results are obtainable as laboratory experiments. I believe that I am in possession all the reports which have been referred to, and hitherto the amounts of chlorine which have been used for sewages and dirty waters, whilst showing that even such waters were capable of being sterilised, gave very little ground for hoping that the process could be made a practical one.

May I also direct attention to an error in the original paper? I find that the hypochlorite can be purchased at £7 per ton, or less than half the price I first had quoted. This means that about 25,000 gallons can be sterilised for one penny. When electrical treatment can be shown to produce the same effect for less money I will give it further attention.

I am, Sir, yours faithfully,
JOHN C. THRESH.

London Hospital Medical College,
Dec. 15th, 1908

improvements have been made in taking black and white pictures during the past 12 years, and if lens makers, emulsion makers, and machinery makers will do their share great improvement will be possible in animated photography in colours. He emphasised his obligations to Mr. Urban for his assistance in the mechanical part of the work. The lens maker has done nothing so far to contribute towards this success and Mr. Smith wants him to do so. Mr. Smith, moreover, has to take the ordinary film used for black and white work and to sensitise it himself to make it see colours as he wants it to. He stated that he has to make a harmony between the human eye and the plate, as if the average observer were asked to state in order the luminosity values of colour he would probably put white at the top and then give yellow as the next brightest colour, afterwards naming in order orange, red, green, blue, and violet, but the photographic plate does not give that answer at all. The photographic plate says white at the top but blue next, and it places yellow very low down in the list and red it scarcely knows anything about at all. It was thus necessary to alter the plate to make it see colour as we see it. Mr. Smith added the interesting information that it was in watching the brilliant uniforms at the funeral service at Windsor of the late Queen Victoria that he first took an interest in colour photography, regretting that he could not record the scene. Mr. Smith showed on the screen several attractive and life-like pictures, including persons with pink dresses, red coats, green sashes, red parasols, plaid shawls, and so forth—viz., "An Animated Duchess of Devonshire," a lady smelling and admiring differently coloured flowers, a row on the sea, a motor-boat race, Henley Regatta, a game of croquet, the red-coated Gordon Highlanders marching to church at Aldershot, a grey donkey eating carrots, a rabbit-hutch with rabbits of several colours and green cabbage leaves, the band of the Cameron Highlanders marching down the West Pier at Brighton, a farmyard, and a scene entitled "Reaping" where the sleek or glossy brown of the horses' coats was admirably and perfectly rendered, as also was the glitter of the varnish on a racing yacht as it veered in the sunshine. Sir Henry Truman Wood thought that the greys, most difficult usually to render, were perfect, but the blues and the greens might be slightly improved; he added that if nothing further were done a great advance had been made and the meeting would be a memorable one. A hearty vote of thanks to Mr. Smith and Mr. Urban terminated the meeting.

THE LATEST "LUSUS NATURÆ."

SPANISH journals are commenting in the day now passing on a "lusus naturæ" which to them is as strange as any recorded in the annals of teratology. To the headquarters of his mission in Spain, the Father Agostino Camarizano writes from Alanquer in Manaos that a fisherman's wife, approaching her confinement, having missed her husband for many hours, went down to the seashore in quest of him, only to find his dead body lying on a rocky recess. He had manifestly been killed in an encounter with a huge serpent, which was still coiled round him—a reptile known in those parts as the "giboia." Frantic under the impression of the gruesome spectacle the poor woman was shortly afterwards seized with the pains of parturition and was delivered of a male child, in all respects normal but covered with a skin resembling that of the "giboia," having similar scales and markings, red and black. This integument the practitioner who was called in found to be non-adherent to the true skin, the "cutis vera"; it simply covered the normal epidermis. To keep the child alive it had to be kept continually moist on the surface, necessitating frequent bathing throughout the 24 hours. If the bath was suspended for any considerable part of the day the skin with its scales began to swell. Further, the woman told her medical attendant that when she gave it the breast the infant would make with its tongue a kind of tiny hiss resembling that of the reptile. All this notwithstanding, the Father Agostino baptised the little monster in the chapel of the Alanquer Mission, and the local authority has made an official entry of the birth in the parish register. This latest Spanish freak is probably not so fabulous as at first sight it appears, inasmuch as it is, no doubt, an example of so-called fœtal ichthyosis. In this condition the skin of the fœtus is covered by thick horny epidermic plates, yellowish in colour, separated by fissures of a red or bluish tint. The appearance has been compared to that of a coat of mail, or to the covering of an armadillo, and it is not surprising therefore that the ignorant Spaniards should have thought the infant was covered with the skin of a serpent. The story that the medical man called in found a sort of outer covering for the true skin is in accordance with the fact that the scales are derived from the stratum corneum, the rete Malpighi being practically unaltered. It is of extreme interest to note in the description of this so-called monster that it was necessary to keep the skin constantly moistened with water, since in these cases there is very marked atrophy of the sebaceous glands. As Ballantyne points out in his interesting account of this rare condition, the weak and buzzing cry, which might well be thought to resemble the hiss of a serpent, was called attention to by Vrolik as long ago as 1849 and is due to the extreme eversion of the lips and the marked deformity of the mouth which are usually present. Naturally enough, a maternal impression is invoked as the cause of such a monster. As a matter of fact, this disease usually develops as early as the fourth month of intra-uterine life, and in the great majority of cases both parents are quite healthy, although it occasionally affects successive children of the same mother.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

ON Dec. 14th, at Marlborough House, the Prince of Wales presided over a general meeting of King Edward's Hospital Fund for London, when it was stated that the amount received by the Fund for the present year up to Dec. 10th and after payment of expenses amounted to £156,748. In moving the adoption of the report, which was carried unanimously, the Prince of Wales said that the donations for 1903 included the munificent gifts of £100,000 from Lord Mount-Stephen and £10,000 from Lord Iveagh, both sums being placed to capital. His Royal Highness referred with satisfaction to the fact that the Fund had been able to allocate to hospitals, convalescent homes, and country sanatoriums for consumption £140,000, an increase of £19,000 over the sum distributed last year. Among the largest grants are that of £5000 more to the removal fund of King's College Hospital, making a total of £27,000 granted to this hospital for the purpose, and £12,000 to the London Hospital, including £2000 towards the reduction of its debt. The report is a very satisfactory one and as his Royal Highness pointed out it is most encouraging to think that in the past ten years almost without exception there has been a steady increase in the annual amount available for distribution. The Fund continues to encourage the amalgamation of the smaller hospitals and also adheres to the policy of aiding the extension of hospitals situated in, or near to, the poorer districts and remote from the larger general hospitals. In the report of the Convalescent Homes Committee it is noted with regret that the number of sanatoriums for consumption which have applied for grants is small and the committee also calls attention to the however, they fail to avail themselves of this teaching they are to be menaced by the law, snatched from their homes and forcibly isolated. But have the teachers themselves always profited by every opportunity of learning? How about the Johns Hopkins Hospital? It is not afflicted with poverty. Money has been lavished so that the latest improvements might be introduced. Nor is it in the hands of "a class of people that cannot be taught." On the contrary, it is a seat of learning and an annexe of the Baltimore University. Nevertheless, extraordinary ignorance is displayed in regard to so important a matter as ventilation. An elaborate system for providing such an essential as pure air at a desirable temperature is allowed to fall into disuse. The principal object-lesson which could have been provided to the visitors who came from all parts of the world and who, in many cases, had been students of Dr. Billings's work was completely lost sight of. What was most in the minds of those who received us was not the Johns Hopkins Hospital itself but a recently constructed annexe known as the Phipps Dispensary. This is simply an out-patients' ward devoted solely to cases of tuberculosis—an excellent thing in its way but I failed to see anything specially novel or instructive in its structure. A few patients come here on their own initiative but the greater part are sent by the visiting nurses or are transferred from the general out-patient wards. This dispensary has no beds at its disposal but works in conjunction with the city and Jews' hospitals for advanced cases. It has been in existence for three years, with about 600 patients the first year, 800 the second year, and 1000 the third year. This is the largest dispensary in Baltimore and there is a sanatorium at Endowood with 30 beds for advanced cases and 60 beds for incipient cases. Then there are 150 beds in the city hospitals for cases of tuberculosis; altogether there are 250 beds available for the treatment of this disease. The State of Maryland is now building a sanatorium for 300 early cases, but as it is estimated that there are some 10,000 such cases in this State it does not seem that Maryland has very much to teach Europe in this respect. On the other hand, the book on ventilation by Dr. Billings is the work of an American which is known and highly appreciated in Europe. Therefore the visitors who came to Baltimore from Europe would have been greatly edified if they could have seen a practical application of Dr. Billings's teaching.

In all other respects the visitors to Baltimore can only congratulate themselves on the excellent reception which they enjoyed. The greatest care was taken of them, every courtesy was shown, and all left Baltimore with regret at parting so soon from such amiable hosts. Dr. T. B. Futcher, the chairman of the reception committee, was indefatigable and Dr. Henry Barton Jacobs entertained all the visitors to an excellent banquet. The greatest friendliness and cordiality prevailed and our hosts showed a truly international spirit in the welcome which they gave us.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

Professor Hillhouse, who has been connected with Mason College and with the University for about 25 years, and who has held the chair of botany in both institutions, has informed the council that he wishes to retire from active work at the end of the present academic year. He is one of the oldest members of the staff and all his colleagues regret the long-continued ill-health which has made Professor Hillhouse feel that he must lead a less laborious life. He is well known and universally respected and will carry with him not only the good wishes of the University staff but also of a large circle of friends.

The Women's Hospital.

A new branch of the Women's Hospital League has recently been instituted in Moseley, a wealthy residential district quite capable of providing the whole of the additional £1000 a year which it is one of the league's objects to attain, and if the local branch now instituted works energetically and tactfully the result of its efforts will be very valuable to the Women's Hospital. In proposing the formation of the branch, Mrs. Nettlefold, the president of the league, gave an interesting *résumé* of the histor of the hospital. It was established at first in small private house in the Crescent which provide eight beds. In a few years expansion became necessar and the committee secured a farmhouse in Stratford-roa which was capable of adaptation. The building wa gradually enlarged until the number of beds was increase to over 30 and excellent work was done. Further enlargement in Stratford-road eventually became impossible, bu the increase of the work continued, so a building fund wa started and the present in-patient hospital and convalescen home in Sparkhill were obtained. 60 beds are now availabl and an additional £1000 a year has become a necessity if th work is to be continued properly. Mrs. Nettlefold struck th right note when she pointed out to the large meeting whic she addressed the fact that the hospital was doing specia work, that it required special appliances, and that if th work done was to produce the greatest advantage the hospital must be kept in the front rank of the Birmingha hospitals. During the time that the hospital has been in existence the death-rate for the special conditions with whic it deals has fallen from 60 per cent. to 2¾ per cent., an the difference between the two rates means a very grea alleviation of suffering. Any very considerable further fal of the mortality rate is not possible but the work of the hospital can still be increased, and the object is one which ought to appeal strongly to all the women of Birmingham, and particularly to those who are themselves to a certain extent shielded from the dangers to which their less fortunate sisters are exposed.

The Research Defence Society.

A general meeting of the Birmingham branch of the Research Defence Society was held on Dec. 11th. Professor R. F. C. Leith, who occupied the chair, referred to the objects of the society and pointed out that when the branch was started in May last it possessed only 14 members. Since then 68 additional members have joined, of whom 30 are non-medical and five are ladies. The society now includes many of the influential and thoughtful citizens of Birmingham, who recognise that the primary object of man is the welfare of mankind. The meeting appointed a small executive committee, to which it gave a general instruction to take the necessary steps to bring the objects of the society before the general public.

Jubilee of the Birmingham Dental Hospital.

The jubilee of the Birmingham Dental Hospital was celebrated on Dec. 10th by a reception which was especially well attended. After the reception the prizes won during the year were presented to the successful students by Mr. Matheson who gave an interesting address upon the Relation of the Teeth to General Health. The fiftieth anniversary of the foundation of the hospital has happened to fall in the year which has shown by the increased entry of students that the public are beginning to realise that the Birmingham Dental School is one of the best-equipped schools in the country and for that reason, together with the fact that it is intimately associated with the University, it offers special facilities to the dental students who have every opportunity of preparing themselves for the diplomas of the various licensing bodies or the degrees of the University, whilst at the same time they have unrivalled opportunities of obtaining that practical experience which is so essential for future success.

The New Dispensary Scheme.

It is intended to commence the work of the new provident dispensary with the coming of the New Year and steps are being taken to bring the scheme to the notice of that part of the public which is likely to make use of it. The objects of the scheme are to give facilities to those who cannot pay ordinary fees but who are still able to pay something for medical help and to reduce the pressure in the out-patient departments of the hospitals. The committee of control consists of seven adult members of the dispensary; seven members of the medical profession nominated in the first instance by the General Medical Practitioners' Union and afterwards appointed annually, one by each of the seven branches of the dispensary staff; seven members appointed by the Birmingham branch of the British Medical Association; the remaining eight members of the general committee are appointed as follows—one by each of improvements have been made in taking black and white pictures during the past 12 years, and if lens makers, emulsion makers, and machinery makers will do their share great improvement will be possible in animated photography in colours. He emphasised his obligations to Mr. Urban for his assistance in the mechanical part of the work. The lens maker has done nothing so far to contribute towards this success and Mr. Smith wants him to do so. Mr. Smith, moreover, has to take the ordinary film used for black and white work and to sensitise it himself to make it see colours as he wants it to. He stated that he has to make a harmony between the human eye and the plate, as if the average observer were asked to state in order the luminosity values of colour he would probably put white at the top and then give yellow as the next brightest colour, afterwards naming in order orange, red, green, blue, and violet, but the photographic plate does not give that answer at all. The photographic plate says white at the top but blue next, and it places yellow very low down in the list and red it scarcely knows anything about at all. It was thus necessary to alter the plate to make it see colour as we see it. Mr. Smith added the interesting information that it was in watching the brilliant uniforms at the funeral service at Windsor of the late Queen Victoria that he first took an interest in colour photography, regretting that he could not record the scene. Mr. Smith showed on the screen several attractive and life-like pictures, including persons with pink dresses, red coats, green sashes, red parasols, plaid-shawls, and so forth—viz., "An Animated Duchess of Devonshire," a lady smelling and admiring differently coloured flowers, a row on the sea, a motor-boat race, Henley Regatta, a game of croquet, the red-coated Gordon Highlanders marching to church at Aldershot, a grey donkey eating carrots, a rabbit-hutch with rabbits of several colours and green cabbage leaves, the band of the Cameron Highlanders marching down the West Pier at Brighton, a farmyard, and a scene entitled "Reaping" where the sleek or glossy brown of the horses' coats was admirably and perfectly rendered, as also was the glitter of the varnish on a racing yacht as it veered in the sunshine. Sir Henry Truman Wood thought that the greys, most difficult usually to render, were perfect, but the blues and the greens might be slightly improved; he added that if nothing further were done a great advance had been made and the meeting would be a memorable one. A hearty vote of thanks to Mr. Smith and Mr. Urban terminated the meeting.

THE LATEST "LUSUS NATURÆ."

Spanish journals are commenting in the day now passing on a "lusus naturæ" which to them is as strange as any recorded in the annals of teratology. To the headquarters of his mission in Spain, the Father Agostino Camarizano writes from Alanquer in Manaos that a fisherman's wife, approaching her confinement, having missed her husband for many hours, went down to the seashore in quest of him, only to find his dead body lying on a rocky recess. He had manifestly been killed in an encounter with a huge serpent, which was still coiled round him—a reptile known in those parts as the "giboia." Frantic under the impression of the gruesome spectacle the poor woman was shortly afterwards seized with the pains of parturition and was delivered of a male child, in all respects normal but covered with a skin resembling that of the "giboia," having similar scales and markings, red and black. This integument the practitioner who was called in found to be non-adherent to the true skin, the "cutis vera"; it simply covered the normal epidermis. To keep the child alive it had to be kept continually moist on the surface, necessitating frequent bathing throughout the 24 hours. If the bath was suspended for any considerable part of the day the skin with its scales began to swell. Further, the woman told her medical attendant that when she gave it the breast the infant would make with its tongue a kind of tiny hiss resembling that of the reptile. All this notwithstanding, the Father Agostino baptised the little monster in the chapel of the Alanquer Mission, and the local authority has made an official entry of the birth in the parish register. This latest Spanish freak is probably not so fabulous as at first sight it appears, inasmuch as it is, no doubt, an example of so-called fœtal ichthyosis. In this condition the skin of the fœtus is covered by thick horny epidermic plates, yellowish in colour, separated by fissures of a red or bluish tint. The appearance has been compared to that of a coat of mail, or to the covering of an armadillo, and it is not surprising therefore that the ignorant Spaniards should have thought the infant was covered with the skin of a serpent. The story that the medical man called in found a sort of outer covering for the true skin is in accordance with the fact that the scales are derived from the stratum corneum, the rete Malpighi being practically unaltered. It is of extreme interest to note in the description of this so-called monster that it was necessary to keep the skin constantly moistened with water, since in these cases there is very marked atrophy of the sebaceous glands. As Ballantyne points out in his interesting account of this rare condition, the weak and buzzing cry, which might well be thought to resemble the hiss of a serpent, was called attention to by Vrolik as long ago as 1849 and is due to the extreme eversion of the lips and the marked deformity of the mouth which are usually present. Naturally enough, a maternal impression is invoked as the cause of such a monster. As a matter of fact, this disease usually develops as early as the fourth month of intra-uterine life, and in the great majority of cases both parents are quite healthy, although it occasionally affects successive children of the same mother.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

On Dec. 14th, at Marlborough House, the Prince of Wales presided over a general meeting of King Edward's Hospital Fund for London, when it was stated that the amount received by the Fund for the present year up to Dec. 10th and after payment of expenses amounted to £156,748. In moving the adoption of the report, which was carried unanimously, the Prince of Wales said that the donations for 1908 included the munificent gifts of £100,000 from Lord Mount-Stephen and £10,000 from Lord Iveagh, both sums being placed to capital. His Royal Highness referred with satisfaction to the fact that the Fund had been able to allocate to hospitals, convalescent homes, and country sanatoriums for consumption £140,000, an increase of £19,000 over the sum distributed last year. Among the largest grants are that of £5000 more to the removal fund of King's College Hospital, making a total of £27,000 granted to this hospital for the purpose, and £12,000 to the London Hospital, including £2000 towards the reduction of its debt. The report is a very satisfactory one and as his Royal Highness pointed out it is most encouraging to think that in the past ten years almost without exception there has been a steady increase in the annual amount available for distribution. The Fund continues to encourage the amalgamation of the smaller hospitals and also adheres to the policy of aiding the extension of hospitals situated in, or near to, the poorer districts and remote from the larger general hospitals. In the report of the Convalescent Homes Committee it is noted with regret that the number of sanatoriums for consumption which have applied for grants is small and the committee also calls attention to the questions of property as administered by the Chancery Division of the High Court.

It is most satisfactory to know that steps are apparently now to be taken to put an end to the state of affairs, almost unthinkable in a public hospital, but which now exists at the infirmary as a result of the action of the governors last February in prohibiting any religious service in the infirmary.

Dec. 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Women Graduates and the University Franchise.

As has been noted in THE LANCET from time to time, some of the women graduates of the Universities of St. Andrews and Edinburgh had carried to the Court of Session in the first place, and to the House of Lords finally, the contention that they were entitled to vote at the election of a Member of Parliament for the Universities in virtue of having received the University degree and of being enrolled as members of the general council of their University. The House of Lords gave its decision on Dec. 10th and, as was anticipated by those who followed the case, the decision was adverse to the claims of the women. The Lord Chancellor stated that two points had been raised: (1) the right to vote and (2) the right to get voting papers; and he dealt with the questions in that order. He held that no authentic and plain case of a woman giving a vote had been submitted, although various anomalies may have occurred and been overlooked in confused times. A few equivocal cases had been referred to and he was surprised how few they were. In regard to judicial precedents, two passages might be found in which judges are reported as saying that women may vote at Parliamentary elections, but these dicta were derived from an ancient manuscript of no weight. Lord Coke referred to the disability of women, and this disability, the Lord Chancellor held, had been taken for granted. He thought it incomprehensible that anyone acquainted with our laws and the methods by which they are ascertained could think there was room for argument on such a point. It was notorious that the right of voting has been confined to men. Not only has it been the constant tradition but it has been the constant practice from the earliest times. Numberless rights rest upon a similar basis; indeed, the whole body of the common law has no other foundation. He held that if this legal disability is to be removed it must be done by Act of Parliament. The appellants hold that it has been so removed, but the Lord Chancellor equally strongly sets aside this contention. Lord Robertson followed the same line; arguing in detail against the view that Parliament in the case of the Scottish Universities had departed from the fact that from immemorial time men only had voted. The appeal was dismissed with costs.

The Bill for the Registration of Nurses.

On Thursday, Dec. 10th, a meeting was held in the hall of the Royal College of Physicians of Edinburgh to consider the application in Scotland of the Bill for the Registration of Nurses. At a representative meeting the provisions of the Bill were severely criticised and a small committee of nine persons was appointed to consider the provisions in detail.

Infantile Mortality in Edinburgh.

Definite steps are being taken in Edinburgh with a view to the lessening of infantile mortality in the city. It is intended to concentrate effort on the Lawnmarket district of the old town. The scheme which is to be put in operation is to have a large number of voluntary lady visitors whose duty it will be to visit when the birth has been intimated, the intimation now requiring to be made within 24 hours of the birth. The visitors are to be instructed in the management and rearing of babies. The first of a series of lectures with this as their object was delivered last week by Dr. Elsie M. Inglis. Dr. A. M. Williamson, the city medical officer of health, occupied the chair and spoke of the great good which such an army could do towards the uplifting and the educating of the poorer classes and was confident that all doors would be opened readily for their entrance.

The Inebriates Act.

A meeting of the Departmental Committee appointed to inquire into the working of this Act was held in Edin on Dec. 10th. Dr. J. Craufurd Dunlop, inspector und Act, was examined as a witness.

Imbecile Patients in Fever Hospitals.

At a meeting of the eastern district committee of St county council held last week a minute of the hospital mittee was submitted in which it was stated that Dr. Clarkson, Falkirk, had made application on behalf c Scottish National Imbecile Institution, Larbert, for th mission of a number of fever patients from that insti into the county hospital. It was unanimously agreed members of the staffs of the Imbecile Institution an Stirling District Asylum, Larbert, should be admitted hospital in the usual way and that lunatic or imbecile pa should be not admitted.

Kingseat Asylum Statistics.

A return of the salaries and wages paid to asylum of and labourers for the years 1906, 1907, and 1908, whic just been submitted to the Aberdeen Lunacy Board, show the average number of patients has increased durin period from 392 to 411; the staff from 79 to 89; sa and wages only from £2801 to £3129; salaries and w including board, from £3595 to £4017; and under "ding," the wages, including those of tradesmen and temp labourers, had risen from £414 to £565. It was also state the amount of salaries and wages per patient at Kin was well below the average for the Scottish asylums, a that item of the maintenance account Kingseat was abo per patient lower than any of the new asylums.

Death of Mr. William Mackie, M.A., M.D. Aberd., Milwaukee.

Information has just been received of the sudden deat Dec. 8th of Dr. William Mackie of Milwaukee. Dr. Ma was a son of the late Mr. William Mackie, Petty, Fyvie, studied at Aberdeen University, of which he was a grad in Arts and Medicine. About 25 years ago he wen America and in Milwaukee, where he ultimately settled. built up a large practice. He was married to Miss B Mitchell, daughter of the late Mr. George Mitchell, John's Wells, Fyvie, and is survived by his widow and son, who is by profession an engineer. Dr. Mackie was years of age.

Notification of Pulmonary Tuberculosis at Newport.

In accordance with the suggestion of the Local Gov ment Board the town council of Newport has agreed have all deaths from pulmonary tuberculosis intimated to local authority, so that the sanitary inspector can then each case and suggest or carry out disinfection as the circ stances may seem to warrant. A further recommenda was also adopted that the necessary disinfectants should supplied free to parties within the burgh where the med officer considered that they should not be asked to bear expense, it being understood that the expenditure should exceed £5 a year. It was also suggested that antito should be supplied free in similar circumstances and un the same conditions.

Appointment.

Dr. A. Robb (Paisley) has been appointed medical office health of Midlothian, Linlithgow, and Peebles. Dr. Ro who is 38 years of age, is a graduate of Aberdeen Universi For about a year he was attached to the public health depa ment of Aberdeen under Dr. Matthew Hay. In June, 18 he was appointed assistant and deputy officer of health the county of Lanark and held the appointment for nea five years. In March, 1901, he was appointed medical off of health of the burgh of Paisley, a position which he held up to the present time.

Dec. 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Old Age Pensions Act and the Dispensary Medical Office Certificate.

ONE aspect of the Old Age Pensions Act presents a fla which has been energetically exposed by Dr. G. E. Greene of Ferns in a letter to the daily press, as a facto taken out of bed for the first time and was seated in an armchair. Suddenly, about 3.30 P.M., she uttered muffled cries and lost consciousness and her respiration became panting. Her expression was haggard, her face was congested, and her eyes projected. Consciousness was regained in about ten minutes but she remained in a state of hebetude, muttering incoherent words. In the evening she was prostrate and complained of severe headache and vomited. Kernig's sign was not present, the neck was supple, and the pulse was 96 and regular. On the following days she remained in a state of torpor with a severe headache, which nothing relieved, and vomiting. The temperature gradually rose to 103·1° and then fell again. On Dec. 1st the temperature was 101·1° and the wrist-joint was again inflamed. On the 7th the patient was much better and the temperature was 99·5°. On the morning of the 8th she suddenly cried out that she was being suffocated. She was found sitting up in bed and covered with perspiration, her face congested, and her eyes widely open and projecting, as in the previous attack. She was much excited, had the impression that something had burst in her head and that she was about to die, and complained of intense occipital headache. In the evening the temperature was 98·6° and she was calmer and seemed to be entering into a state of coma. She vomited and had severe headache. The pupils were small and did not react to light and there was divergent strabismus. The neck was not stiff but there was a suspicion of Kernig's sign and the plantar reflex was extensor. On the 9th she was comatose. Lumbar puncture yielded blackish-red fluid. Centrifugalisation separated this into a yellowish fluid and a large clot which microscopically was found to consist of pure blood. Direct examination and cultures showed that the fluid was sterile. Death occurred on the following day. The necropsy showed no signs of endocarditis. There was slight interstitial nephritis. The pia mater and the brain were much congested and at the base were blackish subarachnoid clots which descended through the foramen magnum. The condition of the brain was characteristic of cerebral rheumatism. The meningeal hæmorrhage could not be attributed to any other cause than the rheumatism. As regards the nephritis, there was never albuminuria and the arteries were not atheromatous. The symptoms indicated that two attacks of hæmorrhage occurred. Meningeal hæmorrhage has been described in other infectious diseases, such as variola, scarlet fever, measles, tuberculosis, syphilis, septicæmia, influenza, anthrax, diphtheria, and also in acute uræmia.

THE Department of Public Health of Queensland in a bulletin dated Nov. 7th states that for the week ending at noon on that day 1 case of plague was notified—namely, that of a male infant, aged six weeks, who died on Nov. 5th. As regards the Mauritius, a telegram from the Acting Governor received at the Colonial Office on Dec. 11th states that *for the week ending Dec. 10th there* were 7 cases of plague and 5 deaths from the disease. A telegram from the Acting Governor of the Mauritius, received at the Colonial Office on Dec. 7th, states that for the week ending Dec. 6th there was one case of plague and one death from the disease.

L'Académie de Médecine de Paris at its meeting on Dec. 11th awarded the Godard prize for 1903 to the work of Dr. F. W. Pavy on "Carbohydrate Metabolism and Diabetes," translated by Dr. Aigre.

A DISCUSSION will take place on Wednesday, Jan. 13th, 1909, at 8 P.M., at the Royal Sanitary Institute on the Purification of Water by Ozone and other Chemical Substances. The debate will be opened by Dr. S. Rideal and the chair will be taken by Mr. E. B. Barnard, M.P., chairman of the Metropolitan Water Board. A general discussion is invited.

ON Wednesday afternoon, Dec. 16th, the Education Committee of the London County Council adopted a recommendation to ask the Council at its meeting next Tuesday for power to draw a sum of £10,000 from the county rates for the provision of meals to underfed school children. At the same meeting the committee adopted the report of the sub-committee on the medical treatment of children, with special reference to such children as may require operative or in-patient treatment at the hospitals. The recommendation of the sub-committee is that children thus removed from the direct superintendence of the education authority require no further steps to be taken in their behalf, but that the Council should establish school clinics at suitable centres in the metropolis. An amendment, however, was carried to the effect that financial help should be given to the existing institutions taking charge of such in-patients, and that where the required institutions do not exist the Council should consider whether it should make the provision itself.

THE Midwives Act Committee appointed by the Lord President of the Council to consider the working of the Midwives Act held a preliminary meeting on Wednesday afternoon, Dec. 16th, at the Privy Council office. Mr. Almeric FitzRoy was in the chair and all the members were present. The course of procedure was arranged, and it was decided to hold the first meeting for the hearing of evidence on Wednesday, Jan. 20th. It is requested that any communications to the committee may be addressed to the secretary, Midwives Act Committee, Privy Council Office, Whitehall, S.W.

MANCHESTER INFIRMARY.—On Dec. 1st the old infirmary in Piccadilly was left, as it were, desolate by the removal of all the in-patients to the new infirmary in Oxford-road. For some days preparations for the great flitting had been going on; ward equipments, furniture, and other accessories were taken away in vans but the patients still remained. On that day at noon horse ambulances, landaus, &c., drew up at the infirmary entrance and the first relay of patients was carried down the well-worn steps and carefully placed in the various conveyances. There were five city ambulances, the Salford motor ambulance, half-a-dozen landaus, a couple of "taxies," as they have already been dubbed, and the infirmary's own Cheadle Homes omnibus. The surgical cases, of course, required very careful handling, but wrapped up in blankets they were borne down the steps by the strong and willing arms of medical men, students, and nurses without any of the patients being the worse for the removal from ward to ambulance, the journey to Oxford-road, and the welcome change from ambulance to ward again. All this was accomplished in a damp, chilly fog that added much to the weird character of the scene. In spite of the fog, however, crowds of people watched the proceedings to the end, both round the infirmary railings and at the entrance to the hospital in Oxford-road, for any spectacle is attractive to those who have nothing to do. It was somewhat pathetic to notice that many of the patients took little or no interest in what was being done; others were, of course, quite awake to all that occurred. It was no light undertaking to transfer 120 or 130 patients to a new hospital one and a half miles or more away, and all interested were thankful when the task was finished without any mishap. It had been a hard day for all who had helped to carry through the work. Those patients who were not too ill or too tired to notice their surroundings expressed pleasure at the change. They were "comfortable enough" at the old place "but this beats it hollow" and so on. The link with Piccadilly is at last broken and the associations of more than 100 years with the old infirmary and its history are now gone, but it may still be said—Long live the infirmary.

questions of property as administered by the Chancery Division of the High Court.

It is most satisfactory to know that steps are apparently now to be taken to put an end to the state of affairs, almost unthinkable in a public hospital, but which now exists at the infirmary as a result of the action of the governors last February in prohibiting any religious service in the infirmary.

Kingseat Asylum Statistics.

A return of the salaries and wages paid to asylum off and labourers for the years 1906, 1907, and 1908, whic just been submitted to the Aberdeen Lunacy Board, show the average number of patients has increased during period from 392 to 411; the staff from 79 to 89; sal and wages only from £2801 to £3129; salaries and w including board, from £3595 to £4017; and under "p ding," the wages, including those of tradesmen and temp labourers, had risen from £414 to £565. It was also stated the amount of salaries and wages per patient at Kin was well below the average for the Scottish asylums, an that item of the maintenance account Kingseat was abou per patient lower than any of the new asylums.

Death of Mr. William Mackie, M.A., M.D. Aberd., Milwaukee.

Information has just been received of the sudden deat Dec. 8th of Dr. William Mackie of Milwaukee. Dr. Ma was a son of the late Mr. William Mackie, Petty, Fyvie, studied at Aberdeen University, of which he was a grad in Arts and Medicine. About 25 years ago he went America and in Milwaukee, where he ultimately settled, built up a large practice. He was married to Miss B Mitchell, daughter of the late Mr. George Mitchell, John's Wells, Fyvie, and is survived by his widow and son, who is by profession an engineer. Dr. Mackie was years of age.

Notification of Pulmonary Tuberculosis at Newport.

In accordance with the suggestion of the Local Gov ment Board the town council of Newport has agreed have all deaths from pulmonary tuberculosis intimated to local authority, so that the sanitary inspector can then each case and suggest or carry out disinfection as the circ stances may seem to warrant. A further recommenda was also adopted that the necessary disinfectants should supplied free to parties within the burgh where the medi officer considered that they should not be asked to bear expense, it being understood that the expenditure should exceed £5 a year. It was also suggested that antito should be supplied free in similar circumstances and un the same conditions.

Appointment.

Dr. A. Robb (Paisley) has been appointed medical office health of Midlothian, Linlithgow, and Peebles. Dr. Ro who is 38 years of age, is a graduate of Aberdeen Universi For about a year he was attached to the public health depa ment of Aberdeen under Dr. Matthew Hay. In June, 18 he was appointed assistant and deputy officer of health the county of Lanark and held the appointment for nea five years. In March, 1901, he was appointed medical offi of health of the burgh of Paisley, a position which he held up to the present time.

(FROM OUR OWN CORRESPONDENTS.)

The Old Age Pensions Act and the Dispensary Medical Officer's Certificate.

ONE aspect of the Old Age Pensions Act presents a flaw which has been energetically exposed by Dr. G. E. J. Greene of Ferns in a letter to the daily press, as a factor there were very few surgeons like John of Ardern. When the wars lulled the surgeons felt the pinch of poverty and in 1423 they entered into an agreement with the physicians who practised in London to form a single profession. The union did not last long, for the wars began again and the surgeons hurried away to France. In the early Tudor period, when peace became more assured and the standard of living became higher, the surgeons again felt the stress of poverty and made overtures for a union with the barbers. The proposed union fell through, and it was not until 1540 that the Company of Barbers consented to join the fraternity of Surgeons to form the United Company of Barbers and Surgeons, the union being brought about, I believe, by a desire to check the enormous increase in quackery which marked the whole reign of Henry VIII., owing to the Acts of 1511, which successively transferred the licensing of barber surgeons in London to the Dean and Chapter of St. Paul's Cathedral and allowed anyone to practise. The union was advantageous to both parties. The surgeons obtained wholesome financial advice, the goodwill of very worthy citizens, and a local habitation, to say nothing of a lucrative connexion with a number of practitioners who often found it necessary to invoke the assistance of their friends amongst the surgeons. Thus sheltered and protected from the necessity of earning a precarious existence surgery grew and developed into the science which made such remarkable advances during the reign of Elizabeth. The barbers on their side gained in position and influence by the new alliance. They entered heartily into the proposals of the surgeons and acted very much the part that the lay board of a modern hospital does to the medical committee. Surgical education prospered under the sway of the United Company. Lectures were delivered and anatomy was taught by the best teachers of the time, usually by physicians who afterwards attained to eminence, whilst a high ethical standard was enforced by fine and imprisonment. The thoroughness with which surgery was taught is shown by the fact that there were two grades of surgeons in the Company, the one who had passed the ordinary examinations and a second who had taken a higher qualification known as "the Grand Diploma." I should very much like to trace the history of this Grand Diploma. It corresponded in some measure to the Serjeancy in law, to the M.A. at the universities under the old system, or to the Doctorate, and it is represented in modern times by the F.R.C.S. examination. The alliance of the barbers with the surgeons was thus mutually beneficial. But mark what happened as soon as the separation took place. The surgeons almost immediately showed their want of business capacity and proved that they had owed their corporate financial success to the barbers. Within 20 years the Surgeons' Company was bankrupt and discredited. The Master was able to say with truth in his celebrated philippic, "Your theatre is without lectures, your library room without books is converted into an office for your clerk, and your committee room is become his parlour." Without the help of the barbers it is very possible that we might have reached this degree of degradation early in the Stuart period instead of late in Hanoverian times. Now, again, the barbers have shown their old cordiality to us. By a graceful courtesy they have arranged that one of the most eminent members of our profession, who has filled most worthily the office of President of the Royal College of Surgeons of England, shall to-night occupy the Master's chair, and by inviting us here this evening it has enabled us to participate in an occasion which takes us back in memory to a very early time in our professional career. Without further words, therefore, I give you the toast of the evening, "The Worshipful Company of Barbers, root and branch, may it flourish for ever." I would couple with the toast the name of Mr. Sidney Young, the only begetter of this feast, as true a friend of the Company as he is to all who know him and the most distinguished historian of this aspect of our profession. To him we wish continued health, prosperity, and a long life.

The toast was responded to by Mr. SIDNEY YOUNG, Past Master of the Barbers' Company.

The toast of "The Visitors" was proposed by Mr. RICHARD ROBERTS, Past Master of the Barbers' Company, and was responded to by the Bishop of OXFORD (a son of Sir James Paget) and Sir ROBERT BALL.

Sir FREDERICK TREVES proposed "The Health of the Master," dwelling upon the learning and powers of work which he was known to possess, after responding to which Sir JOHN TWEEDY proposed the health of "The Worshipful Company of Grocers" in whose hall the banquet was taking place. The proceedings closed with a few words of reply from Mr. F. A. ROBERTS, Master of the Grocers' Company.

Between the speeches an excellent musical programme was provided by Mr. Tom Clare.

THE FOURTH INTERNATIONAL CONGRESS OF ELECTROLOGY AND RADIOLOGY AT AMSTERDAM.

THIS Congress is held once in three years and is of importance from the fact that not only is nearly every country where the sciences are cultivated well represented, but those who attend make it almost a point of honour to put forth their very best efforts to make the scientific side of the Congress a conspicuous success. That held this year in Amsterdam on Sept. 1st to 5th was no exception to this rule and indeed, under the inspiring influence of the President, Professor J. K. A. WERTHEIM SALOMONSON, it could not very well be otherwise. His own contributions to the proceedings were as extensive as they were important and gave evidence of an enormous amount of painstaking research.

In his opening address the PRESIDENT first expressed his indebtedness to the burgomaster of Amsterdam for his kind encouragement and assistance and also to the university authorities who placed their buildings, rooms, &c., at the disposal of the Congress. He reminded his hearers of the important work done by Dutch men of science for electrical progress—from the "Leyden Jar of Musschenbrock" of Leyden in 1746, of the experiments bearing on the transformation of electricity into heat by Marum in 1785, and right down to the quartz-fibre galvanometer of Einthoven, an instrument of such marvellous sensitiveness and accuracy that it has opened up new avenues of experimental research the existence of which was never before suspected.

In giving a *résumé* of the scientific proceedings it will be best to take the papers in groups relating to each particular branch of the work of the Congress, and we cannot do better than lead off with those bearing on the oldest branches,

Electro-Diagnosis and Electro-therapeutics.

Professor BORUTTAU (Berlin) in his paper on the Current of Action showed how the presence of electrical currents in normal muscle in action could be detected by the electrodes at the sides and ends of the muscle and joining them up to the Einthoven galvanometer above referred to. His paper also dealt with the histological and chemical changes, which were of considerable interest.

The PRESIDENT read a paper on somewhat similar lines—the Currents of Action in Reflex Contraction and Muscular Clonus in the Human Subject. He obtained his currents in practically the same way but used the quadriceps and excited it by means of the patellar reflex. In this way he avoided the confusion that was sure to arise when using an outside current and an instrument so sensitive as Einthoven's galvanometer. The current so obtained was quite free from such disturbance and he had found the method useful in investigating obscure cases of nervous disease.

Dr. HOORIVEG, in dealing with the Law of Excitation of Muscles and Nerves, produced an elaborate discourse all tending to disprove the law of Dubois Reymond.

Dr. CLUZET (Toulouse) made an appeal in his paper for a unification of measurements and methods in electro-diagnosis, a matter upon the desirability of which all are agreed, but it was also agreed that to bring it into practical shape would be attended with no small amount of difficulty.

The PRESIDENT in another paper on the Coefficient of Muscular Contraction and the Coefficient of Polarity drew attention to the fact that there existed a constant relation between the current just sufficiently intense to produce a kathodal closing contracture and an intensity just causing tetanus—this was the coefficient of contraction. The relation between the least current to produce a kathodal

he has obtained by cinnamate of sodium in pulmonary tuberculosis. Both he and Dr. Buisson have used this drug in their clinics. It had been tried previously by Landerer of Stuttgart in intravenous injections of 25-milligramme doses, and in Spain better results have been got with larger doses. M. Reynier uses subcutaneous injections of 10 centigrammes dissolved in 10 cubic centimetres of physiological serum, prolonged over a certain period. In tuberculous patients submitted to this treatment the appetite and nutrition and strength improve, the fever becomes less, the cough clears up, and progressive cicatrisation of the lesions is promoted. M. Reynier warmly recommends a trial of the drug.

The Academy of Medicine.

The Academy of Medicine at the same meeting by 77 out of 81 votes elected Dr. Letulle to the section of pathological anatomy in the place unhappily left vacant by the death of Professor Cornil. Dr. Letulle, who is a physician of the Boucicaut Hospital and an *agrégé* of the faculty, was one of Professor Cornil's most brilliant pupils. He was secretary-general of the International Congress of Tuberculosis.

The Value of Œsophagoscopy in Cases of Cicatricial Stenosis.

At the Paris Hospital Internes' Society M. Suisez showed recently a series of patients suffering from cicatricial stenosis caused by swallowing caustic fluids. All were impermeable to ordinary bougies. Six had undergone gastrostomy and the others were just going to have that operation performed. Not even liquid food could be swallowed. By means of œsophagoscopy in all these cases it proved easy to find the narrow lumen, which was often situated eccentrically, and to pass a filiform bougie, then either by simple dilatation with progressively larger bougies or by the use of a circular electrode, to restore the calibre of the œsophagus gradually to nearly its normal size. All these patients are now able to feed themselves and the gastric fistulæ have been allowed to close up.

The Treatment of Cancerous Diseases by Fulguration.

At the Paris Society of Medicine M. de Keating-Hart expounded his method, which is a combination of a powerful high-frequency current with excision of the affected parts.[1] This surgical intervention in the cases shown dealt only with the macroscopic lesions, and its incompleteness affords a proof of the specific activity of the rays which remove that portion of the growth which cannot be seen. The technique is by no means simple, which accounts for numerous failures. On the other hand, the favourable results are increasing, as was proved by the patients shown at the demonstration.

The Indications for Inferior Tracheo-bronchoscopy.

At the meeting of the Paris Society of Medicine M. Cauzard read a paper upon this subject. Inferior tracheo-bronchoscopy is that form in which the instrument is introduced through a tracheotomy wound. It is true that this method has the disadvantage of requiring a tracheotomy wound; but, on the other hand, it has the following advantages over the bronchoscopy per the larynx. It permits of the introduction of a larger tube, of easier manipulations, and of the use of larger forceps and other instruments. M. Cauzard referred to two cases, the one occurring in the practice of M. Variot and M. Cuisez, and the other in his own. In both patients a bean had become impacted in the bronchus and could not be removed by bronchoscopy through the mouth and larynx (*bronchoscopie supérieure*) and in both cases there was no time to do a second operation after tracheotomy. M. Cauzard drew the moral that in cases of impaction of beans and other bodies which become soft and pasty tracheotomy and inferior bronchoscopy should be the operation performed from the first.

(FROM OUR OWN CORRESPONDENT.)

Hospital Service.

INTERNATIONAL congresses of professors and practitioners of the healing art have many attractions for those who frequent them—not the least of these being the insight which they afford into the management and service of the hospitals characteristic of the country in which the congresses are he Italian physicians and surgeons have been heard to say t when such an occasion takes them to the British Isles t have, *inter alia*, been specially interested in the econor equipment, and general efficiency of the great charita institutions in which disease or injury is gratuitously treat interested not only in the professional skill of the clinic but also in that of the subordinate *personnel*—to wit, nurses and the assistant staff in general—organised in patients' service. Not only so, but the air of comfort, e of good cheer, pervading the wards, coincident with cleanliness, a tidiness, a diffused sense of the "becomin (Plato's τὸ πρέπον), are coefficients all making for recov or cure; the *ensemble* in itself constituting an object-les amounting to an admonition which the foreign, particula the Italian, visitor may well profit by. Italy indeed much leeway to make up before her "ospedali," even in great centres of population, can court comparison with humblest infirmaries or hospitals in the British Isles. that she is behindhand in the clinical, or purely prof sional, side; but in the subordinate *personnel* just referred above all in the assistant staff on which the physician surgeon must rely—to say nothing of the features of com and cleanliness already noted—she is lamentably defect. A great congress has lately been held at Siena to discuss to formulate the innovations required to remedy this stat things—a "Congresso degli Infermieri" (hospital "helps the second of a series which, I fear, bids fair to be extended one before the desired consummation is brou about. Inadequate in number and miserably underpaid th "infermieri" complain that there is no attraction for d qualified aspirants to join their ranks, their remunerat being barely enough to keep soul and body together, with ab lutely nothing on which to support a family or to provide old age or supersession by illness. In terms urgent in tone even pathetic in language they call upon the Governmen take prompt and practical cognisance of their circumstanc and they remind the Premier, Signor Gioletti, and administration of the promises obtained from them Signori Barzilai and Turati that 1909 would see them plac in conditions under which they could live and thrive in th honourable service. Failing this reform, they admon the Government that a resignation of the "infermie *en masse* throughout the whole country must surely foll Seldom has a better justified appeal been made to Par ment. Indeed, the lay journals are supporting it, not o in the interests of the public but to avert what threaten become a national scandal. Hardly a week passes with painful incidents being made *publici juris* as to the *vie int* even of the metropolitan hospitals—in which deeds of violer mutiny, flight of patients from the wards bear testimony too eloquent to the deficiency of the "infirmieri" in poin number and competence. In Rome on the same day occur two such scenes—one in the Policlinico, another in Santo Spirito—as would of themselves suffice to hasten to give lasting effect to the appeal of the Siena Congress. the former a surgical patient, a married man with a fam received a visit from a girl with whom he had been on te of improper intimacy. At once they exchanged hea language, followed by the girl's wounding the patient the left scapula with a stiletto. The man promptly sei the weapon, leaped out of bed, and dealt a violent blow the girl who fell wounded in the abdomen. Her cries brou the "infermieri" to the spot, followed by the surgeon duty—the patients in the ward meanwhile drawing th coverlets over their heads in horror at the spectacle. B assailant and assailed were put under special treatment no instant too soon, the result of which has yet to be made kno In the latter hospital, the Santo Spirito, there was a mutiny the patients, beginning with one of these launching a cup in the face of a nurse (because the bread which she handed to him was not to his liking) and inflicting a deep wound in the left parietal region. This outrage was followed by another in the consumptive wards where a patient (having managed clandestinely to get wine) began, in his excitement, to denounce vociferously the whole *personnel* of the hospital where, he said, the victims to tuberculosis were maltreated. Protesting that he would go out, he was conducted to the isolation hall when, swinging an iron bar, *en route*, he swore he would break the head of anyone who came near him. He then called on other patients to join him, and several of these, laying hold of any weapon that seemed handy, threatened

---

[1] THE LANCET, Nov. 14th, 1908, p. 1436.

Dr. HALLS DALLY (London) explained in his paper—which his absence was read by Dr. REGINALD MORTON (London) the great accuracy with which it was possible to measure e various respiratory movements by the aid of the orthoiagraph.

Dr. HENRARDE (Brussels) explained his method of extractig foreign bodies from the œsophagus with the aid of the corescent screen.

Radiotherapy.

Almost the first thing thought of when this subject is entioned is that of x-ray measurement, and the upperost thought in the minds of many was one of questionng as to the probability of some satisfactory method eing forthcoming. Now that it is all over it must e confessed that we are very much where we were. t the same time we did not come altogether empty away s further experience has shown that some of the earliest nethods are quite capable of giving very even results in ctual practice.

Dr. HARET read the first paper on this subject in which he dvocated the use of the Sabouraud pastille.

This brought the PRESIDENT to his feet who spoke against the method in the strongest terms. The fact that it was entirely inaccurate and untrustworthy in a moist climate such as that of Amsterdam was sufficient to prove its unsuitability for any accurate work. His method was to measure the quantity of energy put into the focus tube. In any given x ray outfit this would be determined by the voltage and ampèrage in the primary and the equivalent spark-gap in the secondary. By keeping all these constant he found that he could rely with confidence on obtaining the same dose.

Professor OUDIN agreed with the President and thought that the only variable factors should be distance and time.

Mr. KLINGELFUSS (Switzerland) also found that the measurement of the primary energy was sufficient and in his hands had given results that were quite satisfactory. Each worker had of course to determine the factors for his own apparatus by experience.

Professor BÉCLÈRE apparently uses most, if not all, of the methods at the same time but he admitted that he could not do without the measurement of the primary energy and the time. He thought that the criticisms on the Sabouraud pastille had been unnecessarily severe.

Dr. LURASCHI (Italy) thought the solution of the problem would be found to lie in the use of the selenium cell the resistance of which changed under the influence of x rays. It may be pointed out, however, that there is no evidence to show that this property runs parallel to that of producing histological changes in living tissues.

Dr. DEANE BUTCHER (London) gave his experience in the Use of Radium for Treatment. He is the fortunate possessor of a very excellent specimen which is no doubt a powerful factor in the results attained. He dwelt specially on its analgesic and antipruritic properties which he thought were due to the decomposition of lecithin in the nerve fibres. He had found it useful in lupus, epithelioma, and primary syphilitic chancre.

Dr. HAUCAMPS (Brussels) also had good results with radium in epithelioma and the resulting scar was always very satisfactory as regards softness and elasticity.

Dr. VAN DER GOOT and Professor SCHIFF both related their experiences with x rays in cutaneous diseases, including epithelioma, and showed photographs of successful cases.

Mr. DESSAUER described his method of treating deep-seated malignant disease. To get more even irradiation of the deeper structure he removed the tube some distance from the patient and made up for the loss in power by having six or more tubes at work at the same time and a long exposure. Further experience was necessary to test the value of the idea.

With regard to the exhibition the radiographs of Dr. Leonard, Dr. Hulst, and Professor Wenckebach mark a very great advance in radio-diagnosis. To anyone who has not kept in touch with the latest progress they would come as a perfect revelation. The same also applies to the lantern slides, &c., shown by the President of muscle currents, &c. Apart from the extensive exhibit he gave to the Congress a demonstration in his own laboratory of the way in which these were prepared. Among x ray tubes the most noteworthy was the regenerating tube of Bauer. This was effected on the principle that a certain kind of porcelain was pervious to air but not to mercury. Normally the porcelain disc mounted in the tube was covered with mercury, but when the latter was temporarily displaced a minute quantity of air percolated through the disc and so lowered the vacuum of the tube. Among apparatus those of Snook, Schall, and Grisson should be mentioned. They all aimed at the same thing—viz., to produce a uni-directional current for x ray work and so to eliminate the inverse discharge which was such a bugbear to coil users. All of these achieved the same end, each in its own way, but the Snook apparatus was the most powerful and could pass the largest currents through the x ray tube. The whole arrangements, social and scientific, reflect the greatest credit on the President and the committee. The next Congress in 1910 is to be held in Barcelona.

MEDICINE AND THE LAW.

The Case of Elizabeth Whitaker.

THE manner in which an inquest was held recently at Cowling, near Keighley, in the West Riding of Yorkshire, by the district coroner, Mr. Edgar Wood, led to an application being made in the King's Bench Division that the inquisition should be quashed and a fresh inquest held. The deceased was the daughter of a small farmer who with his family occupied two farmhouses situated about half a mile apart. The father and mother with four daughters and a son lived at Park Farm, and the deceased, who was 23 years of age, lived with two brothers of the respective ages of 20 and 11 years at Lumb Farm. On the evening of Nov. 11th the deceased was in the farm kitchen with her two brothers until they went upstairs to bed and on the morning of Nov. 12th her dead body, naked except for her stockings and clogs, was found in a partially charred condition with fragments of burnt clothing lying near it in an empty pigsty about 60 yards from the door of the farmhouse. The nature of the inquest, which the coroner held and concluded on the afternoon of the same day at Lumb Farm, may be judged from the statement of counsel in the Divisional Court that two witnesses only were called, no post-mortem examination was made and no medical evidence was adduced, at least four persons who helped to lay out the body were not called, nor were three others who were acquainted with the habits and movements of the deceased. Another exceptional feature of the case was the destruction before the inquest of nearly all the remains of clothing found near the body. This was done by some of the neighbours, including a man named Nelson, who was the tenant of a farm close by. It was carried out after the arrival and departure of a policeman who might reasonably have been expected to take steps to prevent such acts. The jury, on such materials as were laid before them on the afternoon following the death, delivered a verdict that the deceased was found burned to death (a finding based on no evidence) and added that the evidence was insufficient to show how the fire had originated. It was to be expected in the circumstances that suspicion would arise and that uneasiness would prevail in the neighbourhood as to a tragic occurrence the proved features of which were consistent with the commission of a brutal crime. The inadequate nature of the inquiry held by the coroner soon became apparent and attracted attention beyond that of the rustic inhabitants of the district and of their clergyman who was emphatic in the expression of his opinion from the pulpit. It therefore became the duty of the chief constable of the West Riding to move in the High Court that the inquisition should be brought up and quashed and an order made for the holding of a fresh inquest. This was done successfully after the papers had been laid before the Attorney-General and his fiat obtained. The second inquest was held in the Liberal Club at Cowling by the same coroner and jury and a considerable amount of evidence was heard, including that of three medical men, Dr. H. J. Campbell, Dr. J. G. Moffatt, and Mr. A. G. Hebblethwaite, who had made a post-mortem examination of the exhumed body. These gentlemen proved that the body of the dead girl afforded no evidence either of outrage or of any violent or criminal act conducing to her death, thus setting at rest rumours which the absence of medical evidence at the first inquest had allowed to circulate unchecked. Dr. Campbell described the wounds caused by the burning in detail. The charring involved practically the whole of the

he has obtained by cinnamate of sodium in pulmonary tuberculosis. Both he and Dr. Buisson have used this drug in their clinics. It had been tried previously by Landerer of Stuttgart in intravenous injections of 25-milligramme doses, and in Spain better results have been got with larger doses. M. Reynier uses subcutaneous injections of 10 centigrammes dissolved in 10 cubic centimetres of physiological serum, prolonged over a certain period. In tuberculous patients submitted to this treatment the appetite and nutrition and strength improve, the fever becomes less, the cough clears up, and progressive cicatrisation of the lesions is promoted. M. Reynier warmly recommends a trial of the drug.

The Academy of Medicine.

The Academy of Medicine at the same meeting by 77 out of 81 votes elected Dr. Letulle to the section of pathological anatomy in the place unhappily left vacant by the death of Professor Cornil. Dr. Letulle, who is a physician of the Boucicaut Hospital and an *agrégé* of the faculty, was one of Professor Cornil's most brilliant pupils. He was secretary-general of the International Congress of Tuberculosis.

The Value of Œsophagoscopy in Cases of Cicatricial Stenosis.

At the Paris Hospital Internes' Society M. Suisez showed recently a series of patients suffering from cicatricial stenosis caused by swallowing caustic fluids. All were impermeable to ordinary bougies. Six had undergone gastrostomy and the others were just going to have that operation performed. Not even liquid food could be swallowed. By means of œsophagoscopy in all these cases it proved easy to find the narrow lumen, which was often situated eccentrically, and to pass a filiform bougie, then either by simple dilatation with progressively larger bougies or by the use of a circular electrode, to restore the calibre of the œsophagus gradually to nearly its normal size. Her cries brought the "infermieri" to the spot, followed by the surgeon on duty—the patients in the ward meanwhile drawing their coverlets over their heads in horror at the spectacle. Both assailant and assailed were put under special treatment not an instant too soon, the result of which has yet to be made known. In the latter hospital, the Santo Spirito, there was a mutiny of the patients, beginning with one of these launching a cup in the face of a nurse (because the bread which she handed to him was not to his liking) and inflicting a deep wound in the left parietal region. This outrage was followed by another in the consumptive wards where a patient (having managed clandestinely to get wine) began, in his excitement, to denounce vociferously the whole *personnel* of the hospital where, he said, the victims to tuberculosis were maltreated. Protesting that he would go out, he was conducted to the isolation hall when, swinging an iron bar, *en route*, he swore he would break the head of anyone who came near him. He then called on other patients to join him, and several of these, laying hold of any weapon that seemed handy, threatened

Looking Back.

FROM

THE LANCET, *SATURDAY*, Dec. 18th, 1830.

PRACTICAL RIGHTS OF PHYSICIANS AND APOTHECARIES.

To the Editor of THE LANCET.

SIR,—I have just received THE LANCET for the 20th, and therein I find that when speaking of the privileges of physicians, you seem to differ with Mr. Willcock, who maintains that they possessed the power to prepare medicines according to their own prescriptions prior to the passing of the Apothecaries' Act; and moreover, that these privileges were granted them in the "saving rights" of that act. Now there is one question which I hope you will answer in your next Number. Can a physician prepare his own medicines out of London, that is, any-where in the country? For you say yourself, "In a word, neither a fellow of the London College of Physicians, nor a graduate of the University of Edinburgh, can follow the business of an apothecary avowedly as an apothecary in *this town.*" By your merely mentioning "this town," therefore, it would appear that they can exercise the art of an apothecary any-where but there.

I remain, Sir,
Your obedient servant,
AN EARNEST INQUIRER.*

⁂ Physicians did enjoy the right of preparing their own prescriptions before the Apothecaries' Act was passed, but that right was not preserved to them in the saving clause of the Act.—ED. L.

A physician cannot practise as an apothecary, either in or out of London, unless he be a licentiate of the Apothecaries' Company.—ED. L.

---

* "*An earnest* Inquirer:"—In our correspondent's extreme anxiety, he forgot to pay the postage of his letter, which amounted to one shilling and three-pence. It gives us pleasure, at all times, to afford to querists whatever information we may happen to possess respecting any subject on which they may be desirous of obtaining information, and in common fairness we ought to be excused from the payment of postage. The tax of postage, has of late become so exceedingly burdensome, that we have been compelled, in our own defence, to resolve that no letters in future shall be taken from the postman, unless they are postage free. The amount of postage in one week for unpaid letters, has exceeded thirty shillings.—ED. L.

With reference to the then Editor's rebuke to the "Earnest Inquirer" which now (in December, 1908) forms an interesting historical note, we may say that "The British Almanac" for the year 1829 set out the rates of postage for letters then in force. In England, if single, they ranged from "not exceeding 15 miles 4*d.*" to "above 300 miles but not exceeding 400, 13*d*," and above that, for every 100 miles or part thereof, 1*d.* more. The average, however, was about 7*d.* each, exclusive of Members of Parliament who might frank 10 and receive 15 daily. Packets of 1 ounce weight were charged as four single letters. The smallest sheet, if cut in two, was charged double postage. Letters between England and Ireland paid, over and above the common rates, a "packet postage" of 3*d.*, 4*d.*, or 5*d.*, and, if an ounce weight, 9*d.* There was a 2*d.* postage in London, however, for letters going from one part of the town to another (1*d.* in some other towns) and each letter was allowed to weigh not more than 4 ounces. Mr. Rowland Hill's scheme for a penny postage throughout the United Kingdom did not come into operation until Jan. 10th, 1840, every letter at that rate then having to be below half an ounce in weight. It is recorded by one annalist, apparently with pride, that on that day "no less than seven-eights were prepaid."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7639 births and 4834 deaths were registered during the week ending Dec. 12th. The annual rate of mortality in these towns, which had been equal to 15·6 per 1000 in each of the three preceding weeks, declined to 15·5 in the week under notice. During the first eleven weeks of the current quarter the annual death-rate in these towns averaged 14·8 per 1000, and in London the mean rate during the same period did not exceed 14·1. The lowest annual death-rates in these towns last week were 5·6 in Hornsey, 7·5 in Barrow-in-Furness, 8·3 in Wallasey, and 9·1 in Leyton; the rates in the other towns ranged upwards, however, to 23·3 in Wigan, 23·5 in Rochdale and in Stockton-on-Tees, 23·7 in Rotherham and in Middlesbrough, and 26·0 in Oldham. In London the death-rate last week did not exceed 14·3 per 1000. The 4834 deaths from all causes in the 76 towns showed a decline of 29 from the low numbers in recent weeks, and included 412 which were referred to the principal epidemic diseases, and exceeded by 44 the low number in the previous week; of these 412 deaths, 182 resulted from measles, 76 from diphtheria, 48 from diarrhœa, 38 from scarlet fever, 37 from whooping-cough, and 31 from "fever" (principally enteric), and not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 1·3 per 1000, against 1·3 and 1·2 in the two preceding weeks; in London the rate from these diseases did not exceed 1·1 per 1000. No death from any of these epidemic diseases was registered last week in Bolton, Birkenhead, Tottenham, Leyton, or in eight other smaller towns; the annual death-rate therefrom, however, ranged upwards in the other towns to 3·3 in Oldham and in Huddersfield, 4·3 in Leicester, 4·4 in Bury, and 5·1 in Middlesbrough. The 182 fatal cases of measles during last week in the 76 towns showed a further increase of 40 upon the steadily increasing numbers in recent weeks and considerably exceeded the number returned in any previous week of this year; they caused annual death-rates equal to 2·8 in Huddersfield, 2·9 in Grimsby, 3·5 in Bury, 4·3 in Leicester, and 6·5 in Middlesbrough. The 76 deaths from diphtheria also showed a further increase upon recent weekly numbers, and were proportionally most numerous in Salford, Swansea, York, Rhondda, King's Norton, and West Ham; nine fatal cases also occurred in Liverpool and six in Manchester. The deaths attributed to diarrhœa, showed a further marked decline, and were fewer than in any week since the middle of May last. The 38 fatal cases of scarlet fever corresponded with the number returned in the previous week; the highest rates from this disease during the week were 1·2 in Blackburn and 1·5 in Handsworth. The 37 deaths from whooping-cough showed some increase, but were again below the average; the three in Wolverhampton were, however, equal to an annual rate of 1·5 per 1000. The 31 deaths referred to "fever" were fewer than the number in any recent week; the three in Wigan were, however, equal to an annual death-rate of 1·7 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 3831 and 3747 on the two preceding Saturdays, had further declined to 3704 on Dec. 12th; the new cases of this disease admitted to these hospitals during the week under notice were 426, against 495 and 405 in the two preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 334, 318, and 295 in the three preceding weeks, further declined during last week to 284, and were 125 below the corrected average number in the corresponding week of the five years 1903-07. The causes of 52, or 1·1 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were again duly certified in London, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 47 other towns; the 52 uncertified causes of death in the 76 towns included, however, 10 in Liverpool, nine in Birmingham, six in Sheffield, and five in Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·3 16·4, and 16·5 in the three preceding weeks, declined to 15·2 in the week ending Dec. 12th. During the first eleven weeks of the current quarter the annual death-rate in these eight towns averaged 15·1 per 1000, and exceeded by 0·3 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 5·8 and 8·0 per 1000 in

he has obtained by cinnamate of sodium in pulmonary tuberculosis. Both he and Dr. Buisson have used this drug in their clinics. It had been tried previously by Landerer of Stuttgart in intravenous injections of 25-milligramme doses, and in Spain better results have been got with larger doses. M. Reynier uses subcutaneous injections of 10 centigrammes dissolved in 10 cubic centimetres of physiological serum, prolonged over a certain period. In tuberculous patients submitted to this treatment the appetite and nutrition and strength improve, the fever becomes less, the cough clears up, and progressive cicatrisation of the lesions is promoted. M. Reynier warmly recommends a trial of the drug.

The Academy of Medicine.

The Academy of Medicine at the same meeting by 77 out of 81 votes elected Dr. Letulle to the section of pathological anatomy in the place unhappily left vacant by the death of Professor Cornil. Dr. Letulle, who is a physician of the Boucicaut Hospital and an *agrégé* of the faculty, was one of Professor Cornil's most brilliant pupils. He was secretary-general of the International Congress of Tuberculosis.

The Value of Œsophagoscopy in Cases of Cicatricial Stenosis.

At the Paris Hospital Internes' Society M. Suisez showed recently a series of patients suffering from cicatricial stenosis caused by swallowing caustic fluids. All were impermeable to ordinary bougies. Six had undergone gastrostomy and the others were just going to have that operation performed. Not even liquid food could be swallowed. By means of œsophagoscopy in all these cases it proved easy to find the narrow lumen, which was often situated eccentrically, and to pass a filiform bougie, then either by simple dilatation with progressively larger bougies or by the use of a circular electrode, to restore the calibre of the œsophagus gradually to nearly its normal size. All these patients are now able to feed themselves and the gastric fistulæ have been allowed to close up.

The Treatment of Cancerous Diseases by Fulguration.

At the Paris Society of Medicine M. de Keating-Hart expounded his method, which is a combination of a powerful high-frequency current with excision of the affected parts.[1] This surgical intervention in the cases shown dealt only with the macroscopic lesions, and its incompleteness affords a proof of the specific activity of the rays which remove that portion of the growth which cannot be seen. The technique is by no means simple, which accounts for numerous failures. On the other hand, the favourable results are increasing, as was proved by the patients shown at the demonstration.

The Indications for Inferior Tracheo-bronchoscopy.

At the meeting of the Paris Society of Medicine M. Cauzard read a paper upon this subject. Inferior tracheo-bronchoscopy is that form in which the instrument is introduced through a tracheotomy wound. It is true that this method has the disadvantage of requiring a tracheotomy wound; but, on the other hand, it has the following advantages over the bronchoscopy per the larynx. It permits of the introduction of a larger tube, of easier manipulations, and of the use of larger forceps and other instruments. M. Cauzard referred to two cases, the one occurring in the practice of M. Variot and M. Cuisez, and the other in his own. In both patients a bean had become impacted in the bronchus and could not be removed by bronchoscopy through the mouth and larynx (*bronchoscopie supérieure*) and in both cases there was no time to do a second operation after tracheotomy. M. Cauzard drew the moral that in cases of impaction of beans and other bodies which become soft and pasty tracheotomy and inferior bronchoscopy should be the operation performed from the first.

Dec. 14th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Hospital Service.

INTERNATIONAL congresses of professors and practitioners of the healing art have many attractions for those who frequent them—not the least of these being the insight which they afford into the management and service of the hospitals characteristic of the country in which the congresses are held. Italian physicians and surgeons have been heard to say that when such an occasion takes them to the British Isles they have, *inter alia*, been specially interested in the economy, equipment, and general efficiency of the great charitable institutions in which disease or injury is gratuitously treated; interested not only in the professional skill of the clinical, but also in that of the subordinate *personnel*—to wit, the nurses and the assistant staff in general—organised in the patients' service. Not only so, but the air of comfort, even of good cheer, pervading the wards, coincident with a cleanliness, a tidiness, a diffused sense of the "becoming" (Plato's τὸ πρέπον), are coefficients all making for recovery or cure; the *ensemble* in itself constituting an object-lesson amounting to an admonition which the foreign, particularly the Italian, visitor may well profit by. Italy indeed has much leeway to make up before her "ospedali," even in her great centres of population, can court comparison with the humblest infirmaries or hospitals in the British Isles. Not that she is behindhand in the clinical, or purely professional, side; but in the subordinate *personnel* just referred to, above all in the assistant staff on which the physician or surgeon must rely—to say nothing of the features of comfort and cleanliness already noted—she is lamentably defective. A great congress has lately been held at Siena to discuss and to formulate the innovations required to remedy this state of things—a "Congresso degli Infermieri" (hospital "helps"), the second of a series which, I fear, bids fair to be an extended one before the desired consummation is brought about. Inadequate in number and miserably underpaid these "infermieri" complain that there is no attraction for duly qualified aspirants to join their ranks, their remuneration being barely enough to keep soul and body together, with absolutely nothing on which to support a family or to provide for old age or supersession by illness. In terms urgent in tone and even pathetic in language they call upon the Government to take prompt and practical cognisance of their circumstances; and they remind the Premier, Signor Gioletti, and his administration of the promises obtained from them by Signori Barzilai and Turati that 1909 would see them placed in conditions under which they could live and thrive in their honourable service. Failing this reform, they admonish the Government that a resignation of the "infermieri" *en masse* throughout the whole country must surely follow. Seldom has a better justified appeal been made to Parliament. Indeed, the lay journals are supporting it, not only in the interests of the public but to avert what threatens to become a national scandal. Hardly a week passes without [illegible] painful incidents being [illegible] even of the metropolitan [illegible] mutiny, flight of patients from the wards bear testimony all too eloquent to the deficiency of the "infirmieri" in point of number and competence. In Rome on the same day occurred two such scenes—one in the Policlinico, another in the Santo Spirito—as would of themselves suffice to hasten and to give lasting effect to the appeal of the Siena Congress. In the former a surgical patient, a married man with a family, received a visit from a girl with whom he had been on terms of improper intimacy. At once they exchanged heated language, followed by the girl's wounding the patient near the left scapula with a stiletto. The man promptly seized the weapon, leaped out of bed, and dealt a violent blow at the girl who fell wounded in the abdomen. Her cries brought the "infermieri" to the spot, followed by the surgeon on duty—the patients in the ward meanwhile drawing their coverlets over their heads in horror at the spectacle. Both assailant and assailed were put under special treatment not an instant too soon, the result of which has yet to be made known. In the latter hospital, the Santo Spirito, there was a mutiny of the patients, beginning with one of these launching a cup in the face of a nurse (because the bread which she handed to him was not to his liking) and inflicting a deep wound in the left parietal region. This outrage was followed by another in the consumptive wards where a patient (having managed clandestinely to get wine) began, in his excitement, to denounce vociferously the whole *personnel* of the hospital where, he said, the victims to tuberculosis were maltreated. Protesting that he would go out, he was conducted to the isolation hall when, swinging an iron bar, *en route*, he swore he would break the head of anyone who came near him. He then called on other patients to join him, and several of these, laying hold of any weapon that seemed handy, threatened

* Including membranous croup.

Earl Grey, who declared the exhibition open. Amongst others who have delivered addresses were Dr. Herman Biggs, New York; Dr. Knopf, New York; Dr. Charles A. Hodgetts, of the Ontario Board of Health, Toronto; Dr. A. J. Richer, of the Ste. Agathe Sanatorium, near Montreal; Professor Adami and Dr. W. F. Hamilton. Lieutenant-Colonel Burland of Montreal has given $50,000 for a dispensary. Dr. Hamilton thus summed up the needs for the anti-tuberculosis campaign in Montreal: A larger dispensary, soon to be realised through the gifts of Colonel Burland; a quinquennial census of the city; a larger number of nurses; two more inspectors; greater support by the board of health with increased powers; fuller coöperation by the hospitals; a sanatorium in the Laurentian mountains and camps near Montreal; home for incurable cases, with farm attached to accommodate 400 patients; better enforcement of the laws against spitting and the requirement of notification and registration of tuberculous cases. Dr. Hamilton, in his public lecture before the exhibition, told of the work which had been done in Montreal during the past six years. Up to March last 1105 patients have been under supervision during the existence of the Montreal League for the Prevention of Tuberculosis. In the same period 4186 persons have died in Montreal from tuberculosis. 20,000 visits were paid to these 1105 patients, 9000 cuspidors were distributed, 40,000 leaflets were put forth, and 3000 rooms and houses were disinfected. All the work had been done on an expenditure of $12,724.

University of Toronto.

Dr. R. A. Reeve, Dean of the Medical Department of the University of Toronto for the past 12 years, has retired and has been succeeded by Dr. Charles K. Clarke, superintendent of the Toronto Provincial Hospital for the Insane. During his tenure of office Dr. Reeve took a very active interest in all that pertained to the medical department as well as to the wider field of university affairs. He was ever zealous in the cause of the medical students. He was for years President of the Alumni Association of the University, and during the meeting of the British Medical Association in Toronto in 1906 was its President. His valuable experience and services will not be lost to the medical department as he retains his position as professor of ophthalmology, being also chief of that department in the Toronto General Hospital.

Health Report of Ontario for October.

During the month of October there were 500 cases of enteric fever in this province with 126 deaths, compared with 50 deaths for the corresponding month last year. 50 cases of small-pox were reported occurring in 15 centres. The total number of deaths from all causes throughout the province was 2327, making a death-rate of 13·8 per 1000.

Hospital News in Toronto.

The Western Hospital, Toronto, recently received a donation of $25,000 from a citizen of that town. A by-law will be voted on in Toronto at the municipal elections in Jan. 1st, 1909, to provide for the raising of $200,000 to be divided equally between the Toronto General, St. Michael's, Grace, and the Western Hospitals. Dr. D. J. Gibb Wishart, Toronto, has been advanced to the position of chief of the ear, nose, and throat service in the Toronto General Hospital. Mr. I. H. Cameron, LL.D., has been appointed chief of the surgical service in St. Michael's Hospital and Dr. Walter McKeown, chief of another surgical service in the same institution. Dr. H. B. Anderson and Dr. R. J. Dwyer have been made chiefs of the two services in medicine. Dr. F. Fenton is chief of the obstetric service and Dr. G. H. Burnham of the ophthalmology service. Dr. J. N. E. Brown, superintendent of the Toronto General Hospital, is recommending to the board of governors that all "drunks" should be excluded from that institution in the future. Chronic "drunks" should go to the gaol and acute cases to the Provincial Hospital for the Insane until recovered.

Toronto, Dec. 1st.

THE TRURO TOWN COUNCIL AND THE LOCAL GOVERNMENT BOARD.—At a meeting of the Truro town council, held on Dec. 8th, it was decided to acquiesce in the Local Government Board's suggestion that the office of surveyor and sanitary inspector should be held by two persons, instead of by one as hitherto.

Obituary.

CHARLES EDWARD BEEVOR, M.D. LOND., M.R.C.S. ENG., F.R.C.P. LOND.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED EPILEPTIC AND TO THE GREAT NORTHERN CENTRAL HOSPITAL, E

IT is with sincere regret that the medical profession a great number of personal friends have heard of the su death of Dr. C. E. Beevor in the early hours of Dec. due to an attack consequent on an atheromatous conditio the coronary arteries.

Charles Edward Beevor was the eldest son of the Charles Beevor, F.R.C.S., and Elizabeth, daughte Thomas Burrell. Dr. Beevor was born in London in 1854 was educated first at Blackheath Proprietary School and at University College, London. He received his medical ed tion at University College Hospital, becoming M.R.C.S. in 1878, M.B. Lond. in 1879, L.S.A. in 1880, M.D. Lon 1881, and M.R.C.P. Lond. early in 1882. In May, 1882, Beevor was studying at Vienna with Obersteiner and atte various clinics in that city, especially those dealing with throat and the eye. From August, 1882, to May, 1893, his t was passed at Leipsic, at first with Cohnheim and then Weigert, with whom he studied microscope technique and methods of mounting and staining sections. Whilst Leipsic the clinic of the neurologist Erb naturally attra the close attention of Dr. Beevor, after which he repa to Berlin where he divided his time between the var hospitals in that city. The celebrated teachers in P including Charcot, Marie, and Déjerine, were attende various times by Dr. Beevor, and it might be said tha spared no trouble or labour to fit himself by every mean his power for the prosecution of his studies.

In 1883 he became physician to the National Hospital the Paralysed and Epileptic, Queen-square, a post which retained to his death, as was also the case with the offic physician to the Great Northern Central Hospital whic obtained in 1885. He became a Fellow of the Royal Col of Physicians of London in 1888. On his return f Germany in 1883 he was engaged for some four years Sir Victor Horsley on an experimental research, the sub of which was the minute representation of movement in cerebral cortex and in the internal capsule. Notwithsta ing the convincing demonstration that Dr. David Ferrier given at the International Medical Congress held in Lon in 1881, that certain areas of the cortex were defini related to certain motor and sensory functions, opinion remained to a certain extent unstable with regard to fundamental question of cerebral localisation, and research was of far-reaching importance, not only beca it led to a vast increase in our knowledge of the functi of the brain, but also because it had the effect of crystallis in the minds of the profession the truths of cerebral locali tion. From the date of the publication of this work Beevor became one of the recognised neurological aut rities of the country.

Last May he went to the United States in response a pressing and special invitation from the neurologists that country. He lectured in Philadelphia, New York, Chicago. He received a most enthusiastic reception f the American Neurological Society and from the Neu logical Section of the American Medical Association. Lett received from the United States by one of our corresponde in this country showed how deep an impression his visit made and how greatly his personal charm and profou knowledge had impressed American neurologists. The lect which attracted most attention in America was delive before the members of the Section on Nervous and Men Diseases of the fifty-ninth annual session of the Americ Medical Association held at Chicago; the subject of lecture was the Coördination of Single Muscular Moveme in the Central Nervous System. He was also the honour guest of the Neurological Society of America before wh he read a paper on the Arterial Supply of the Brain. Boston the medical profession induced him to address the on Localisation of Brain Centres and accorded to him welcome that was as cordial as it was sincere.

Dr. Beevor contributed many articles to *Brain* and t leading medical journals, his "Handbook on Diseases of t Nervous System" being characterised by such depth of i sight and such marked literary ability that the wo showed the author to be not only master of h

Correspondence.

"Audi alteram partem."

TANDARDISATION OF DISINFECTANTS.

To the Editor of THE LANCET.

SIR,—With regard to Messrs. McDougall's letter on this ubject which appeared in THE LANCET of Dec. 5th, I am esired by my board to state that they fully agree with the riters as to the desirability of a definite method of test for scertaining the germicidal value of disinfectants, and that hilst they see no reason for questioning the sufficiency of e "Rideal-Walker" method they would be among the rst to adopt any better test were it available.

But they cannot agree that because they have now secured e services of Mr. Ainslie Walker, one of the authors of at test, as their managing director and consulting chemist, e test should therefore be in any way discredited. Messrs. IcDougall know perfectly well that when they or we claim certain coefficiency for our respective products that claim s not adjudicated by the authors of the test but by ndependent experts who fully understand the method, as it s now in very general use in this country and elsewhere. hey should also know that the amplification of the test to neet the case of disinfectants that separate out into layers of different coefficiencies is simply a recognition of a practice which has long prevailed and which was foreseen and provided for in the recommendations of the expert committee of the Royal Sanitary Institute.

With regard to the particular questions that have arisen between Messrs. McDougall and ourselves, and which appear to have occasioned their letter to you, we think it undesirable to make any statement at present, seeing that Messrs. McDougall have indicated the possibility of their seeking the intervention of the court in the matter.

I am, Sir, yours faithfully,
For JEYES' SANITARY COMPOUNDS CO., LIMITED,
WM. PLANNER, Secretary.
Cannon-street, E.C., Dec. 14th, 1908.

To the Editor of THE LANCET.

SIR,—As Messrs. McDougall Bros. and Messrs. Jeyes have both been clients of mine in the past, may I write to say that it seems unfortunate that the letter which Mr. Ainslie Walker and myself sent to you on Sept. 19th should have given rise to any dispute. Both firms should be in a position to know what has been done for the standardisation of disinfectants, so that I am surprised at the suggestions which Messrs. McDougall Bros. now make. The whole question may be resolved into a matter of dates.

1. There is already a well-known standard bacteriological test for disinfectants accepted by all workers here and in the colonies. Five years ago the Royal Sanitary Institute appointed a special committee, consisting of members whose qualifications and whose disinterestedness cannot be questioned, to decide on a definite standard. Their labours extended over two years, and their decision has been accepted and made use of by all workers both at home and abroad, and consisted in recommending for general work the test which Mr. Ainslie Walker and myself had *suggested* at Bradford in 1903. It should be pointed out that Mr. Walker's appointment in Messrs. Jeyes' Company was two years after the reading of this paper; but even if this had not been the case it should not detract from the value of our method.

2. The offer of a subscription to the cost of such an inquiry is also somewhat belated. When the question was submitted to the Royal Sanitary Institute, Messrs. Jeyes, through me, formally offered to bear its entire cost, but the institute preferred to meet the expenses out of their own funds and so happily averted the possibility of any suggestion of commercial influence on the result of the committee's work.

3. The last clause of that committee's report read thus: "Where special conditions exist which may interfere with the activity of the disinfectants, the consumer should be advised to call for the same conditions to be embodied in the test." Of late, medical officers of the City of London and other important towns have inserted in their tender forms a stipulation which, whilst requiring no change in the technique of the original test, calls for a modification of the condition in which the disinfectant is presented for examination; and it was with the object of introducing some uniformity in the method of controlling this condition—too indefinite as it stands—that we put forward the suggestion which appears in our letter of Sept. 19th. In that letter we did not intend to modify in any way the value of the simple test as originally put forward and should be very sorry if other readers of the letter should put such an interpretation upon it.

In conclusion, Sir, the matter may be summed up thus: There is, and has been for some years, an authoritative standard which has met with general acceptance. The inclusion of the condition of behaviour on standing has been suggested by several medical officers of health acting in the interests of the public. Both firms tell you that they have some preparation that conforms to the Rideal-Walker test after the disinfectant has been diluted, so proving that this *new condition of non-separation* on standing is fulfilled. I have not yet had an opportunity of examining a sample of Messrs. McDougall's preparation in this way but do not doubt their word. In that case they will be able to compete in the open market under conditions which are open to all other manufacturers. I am, Sir, yours faithfully,

Victoria-street, Westminster, Dec. 11th, 1908. SAMUEL RIDEAL.

⁂ In our footnote to a letter from Messrs. McDougall Bros. we said that there was a need for a standard method of conducting bacteriological tests for disinfectants. Nothing in Dr. Rideal's letter leads us to change our opinion. Dr. Rideal omits to say that the report of the special committee appointed by the Royal Sanitary Institute was not adopted by that body. It is not officially published.—ED. L.

THE VALUE OF CALMETTE'S OPHTHALMO-TUBERCULIN REACTION IN DISEASES OF CHILDREN.

To the Editor of THE LANCET.

SIR,—There has been recently considerable discussion as to the diagnostic value of Calmette's ophthalmo-tuberculin test in tuberculous disease. Whilst some believe it to be of great value, other observers are sceptical of its use, putting forward morbid conditions other than tubercle which give the reaction. Of its use in adult diseases not seen in a children's hospital I have had practically no experience, but venture to think that the following collection of cases clearly shows that the test, at least in children, is highly satisfactory. The solutions used (0·5 per cent. and 1 per cent.) were made from the powder, which is decidedly cheaper and as efficient as that made up ready for use in ampoules. The 1 per cent. is recommended to be used in those cases of suspected tuberculous disease where failure has occurred with the 0·5 per cent., but I found that those rare cases that failed to react with the weaker solution failed also with the stronger, or produced such an indefinite reaction as to be reckoned a query positive. The accepted reaction implies reddening of the ocular conjunctiva, the conjunctiva of lower eyelid and caruncle; but the delicate pink blush of the conjunctiva alone, by far the most frequent manifestation, is sufficient for a positive reaction. Some subjects give the reaction in both eyes when only one has been put to the test, and in one or two cases the opposite eye to that tested has actually been seen to react, the one treated remaining normal.

With regard to the time of reaction, although the whole cycle may be complete in eight hours, the reaction usually begins about the sixth hour, reaches its maximum in 12, and lasts 24 hours. In only one case out of 45 was there the least anxiety felt. Here the patient, a tuberculous child, reacted strongly, causing slight chemosis and photophobia. This, however, cleared up with frequent washings of boric acid lotion in four days.

In all Calmette's solution was used on 45 children varying in age from 3 months to 14 years. Of these 21 gave the positive reaction; 16 were verified by post-mortem examination, and 5 gave clinical evidence of tubercle. Of 17 cases of suspected tubercle, negative to Calmette's test, 9 at the necropsy were found to be free from any sign of tubercle; 5 where an examination could not be obtained gave no clinical

Earl Grey, who declared the exhibition open. Amongst others who have delivered addresses were Dr. Herman Biggs, New York; Dr. Knopf, New York; Dr. Charles A. Hodgetts, of the Ontario Board of Health, Toronto; Dr. A. J. Richer, of the Ste. Agathe Sanatorium, near Montreal; Professor Adami and Dr. W. F. Hamilton. Lieutenant-Colonel Burland of Montreal has given $50,000 for a dispensary. Dr. Hamilton thus summed up the needs for the anti-tuberculosis campaign in Montreal: A larger dispensary, soon to be realised through the gifts of Colonel Burland; a quinquennial census of the city; a larger number of nurses; two more inspectors; greater support by the board of health with increased powers; fuller coöperation by the hospitals; a sanatorium in the Laurentian mountains and camps near Montreal; home for incurable cases, with farm attached to accommodate 400 patients; better enforcement of the laws against spitting and the requirement of notification and registration of tuberculous cases. Dr. Hamilton, in his public lecture before the exhibition, told of the work which had been done in Montreal during the past six years. Up to March last 1105 patients have been under supervision during the existence of the Montreal League for the Prevention of Tuberculosis. In the same period 4186 persons have died in Montreal from tuberculosis. 20,000 visits were paid to these 1105 patients, 9000 cuspidors were distributed, 40,000 leaflets were put forth, and 3000 rooms and houses were disinfected. All the work had been done on an expenditure of $12,724.

University of Toronto.

Dr. R. A. Reeve, Dean of the Medical Department of the University of Toronto for the past 12 years, has retired and has been succeeded by Dr. Charles K. Clarke, superintendent of the Toronto Provincial Hospital for the Insane. During his tenure of office Dr. Reeve took a very active interest in all that pertained to the medical department as well as to the wider field of university affairs. He was ever zealous in the cause of the medical students. He was for years President of the Alumni Association of the University, and during the meeting of the British Medical Association in Toronto in 1906 was its President. His valuable experience and services will not be lost to the medical department as he retains his position as professor of ophthalmology, being also chief of that department in the Toronto General Hospital.

Health Report of Ontario for October.

During the month of October there were 500 cases of enteric fever in this province with 126 deaths, compared with 50 deaths for the corresponding month last year. 50 cases of small-pox were reported occurring in 15 centres. The total number of deaths from all causes throughout the province was 2327, making a death-rate of 13·8 per 1000.

Hospital News in Toronto.

The Western Hospital, Toronto, recently received a donation of $25,000 from a citizen of that town. A by-law will be voted on in Toronto at the municipal elections in Jan. 1st, 1909, to provide for the raising of $200,000 to be divided equally between the Toronto General, St. Michael's, Grace, and the Western Hospitals. Dr. D. J. Gibb Wishart, Toronto, has been advanced to the position of chief of the ear, nose, and throat service in the Toronto General Hospital. Mr. I. H. Cameron, LL.D., has been appointed chief of the surgical service in St. Michael's Hospital and Dr. Walter McKeown, chief of another surgical service in the same institution. Dr. H. B. Anderson and Dr. R. J. Dwyer have been made chiefs of the two services in medicine. Dr. F. Fenton is chief of the obstetric service and Dr. G. H. Burnham of the ophthalmology service. Dr. J. N. E. Brown, superintendent of the Toronto General Hospital, is recommending to the board of governors that all "drunks" should be excluded from that institution in the future. Chronic "drunks" should go to the gaol and acute cases to the Provincial Hospital for the Insane until recovered.

Toronto, Dec. 1st.

THE TRURO TOWN COUNCIL AND THE LOCAL GOVERNMENT BOARD.—At a meeting of the Truro town council, held on Dec. 8th, it was decided to acquiesce in the Local Government Board's suggestion that the office of surveyor and sanitary inspector should be held by two persons, instead of by one as hitherto.

Obituary.

CHARLES EDWARD BEEVOR, M.D. LOND., M.R.C.S. ENG., F.R.C.P. LOND.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED A EPILEPTIC AND TO THE GREAT NORTHERN CENTRAL HOSPITAL, ETC

IT is with sincere regret that the medical profession an great number of personal friends have heard of the sudd death of Dr. C. E. Beevor in the early hours of Dec. 5 due to an attack consequent on an atheromatous condition the coronary arteries.

Charles Edward Beevor was the eldest son of the l Charles Beevor, F.R.C.S., and Elizabeth, daughter Thomas Burrell. BALTIMORE AND THE JOHNS HOPKINS HOSPITAL.

(From our Special Sanitary Commissioner.)

THE city of Baltimore is celebrated throughout the world, at least among University scholars and the medical profession, for its Johns Hopkins University and the Johns Hopkins Hospital. It is only in America that such institutions spring into existence at the bidding of one single individual. This is certainly not an unmixed blessing but it is a very remarkable fact. A merchant named Mr. Johns Hopkins died in 1873 and bequeathed £700,000 so that a university should be established at Baltimore. The special features of this University are the inducements and facilities offered for post-graduate work. So much is this the case that more than half the 700 to 800 students attending have already graduated in other universities. Not only did the late Mr. Johns Hopkins endow the University but he left a sum nearly as large—namely, £600,000—so that a model hospital which should serve as a scientific and charitable institution might be built in connexion with the University. In these circumstances it was only natural that the foreign members of the International Congress on Tuberculosis which recently met at Washington should be invited to visit Baltimore and its University, and this they did in large numbers. They were well received. The services of numerous motor-cars had been secured and in the early morning the visitors were fetched from their various hotels and conveyed to the town hall. Here the mayor and the secretary of the State of Maryland said a few words of welcome and then the automobiles took the visitors over the town and away into the beautiful wooded parks that surround the city. The residential quarters are specially favoured, for the houses are not high and yet many of the avenues are so broad that there are gardens and trees down the centre of these thoroughfares. But undoubtedly the principal object to be seen was the Johns Hopkins Hospital which was reached later in the morning. The magnificence of the site and the abundance of surrounding open space constitute the first favourable impression. This is all the more remarkable as the hospital is not in the outskirts but in the centre of the city, and furthermore it stands on an elevation on the crest of rising ground. Thus outdoor treatment can be employed here. The fine open galleries running from pavilion to pavilion provide broad terraces where beds can be wheeled out and the patients left to enjoy the open air.

There is room in this celebrated hospital for 380 in-patients but some of these are paying patients and are charged £1 (sometimes even £2) a day, all included. Dr. John S. Billings of the United States Army had helped to design the hospital and he is one of the best known authorities on warming and ventilating. In these circumstances I hastened to the surgical ward where it was probable that Dr. Billings's system would be most carefully applied. This is a circular ward, with a big towering shaft in the centre and the beds in the outer circle, their heads being against the wall and between the windows. Dr. Billings prefers this arrangement to that of the circular ward at the Antwerp Hospital, of which he gives an illustration in his text-book. The original object of a circular ward was to disinfect the air that came from small-pox patients. Then the beds were placed against the central trunk or tower; the air came through the outer circle or walls and reached the beds only at the end of its journey, and it was then at once drawn into the tower where it was sterilised by passing through fire before it was discharged into the open. The scheme was to allow 1200 cubic feet of air per bed, so that for 12 beds 120,000 cubic feet of air should be supplied per hour. Primed by these teachings, derived from Dr. Billings's standard work, I naturally inquired to what extent they were realised at the Johns Hopkins Hospital. From the members of the medical staff who were showing us round I first asked what was the cubic space allowed per bed. They did not know. Then I asked what was the system of ventilation. About this they were equally ignorant and it seemed to them quite a new idea to have to consider such matters. Some of the medical men whom I questioned had followed the clinics in this hospital for many years but it had never occurred to them to inquire how the building was warmed and ventilated. It was obvious that an elaborate system of ventilation had been devised but it was equally obvious that no one seemed to have taken any concern about it.

Considering that the visitors to the Johns Hopkins Hospital had come from the Congress on the prevention of tuberculosis; considering that a plentiful supply of fresh air is the best preventive of tuberculosis and a powerful aid in its cure; considering further, that Dr. John S. Billings is one of the greatest authorities on ventilation and that he helped to design the hospital, it was natural to expect that the system of ventilation would have been in full working order and that experts would have been on the spot to explain all the details. As a matter of fact, this most important phase of the problems at issue was entirely overlooked. Yet one of the leading representatives of the medical profession of Baltimore, Dr. Henry Barton Jacobs, had read a paper at the Washington Congress on the necessity of teaching hygiene in the schools. In this paper he said:—"Hospitals, sanatoria, dispensaries, camps may have great influence in alleviating, or even curing, those already infected with tuberculosis or other infectious diseases, but their influence in checking the spread of that disease is to be found in education as to necessary precautions and the proper manner of life. These institutions, therefore, become schools in which *hygiene* is taught to their inmates." Then further he adds: "The public schools, academies, and colleges are a series of institutions which are moulding the growing intelligence of the country, their pupils of to-day will be the men and women of to-morrow, and if in them the same kind of instruction in hygiene could be given in a practical, effective, and convincing manner as is given to patients in sanatoria, they would be sending out into the world a youth ready for the emergencies of life and with an understanding of how to avoid the preventative diseases."

These undoubtedly are excellent sentiments but how are the children in the schools to be taught hygiene when the professors in the universities fail to apply its principles? Having secured the help of one of the greatest living authorities on the subject, the Johns Hopkins Hospital should be an object-lesson to all comers in the science of supplying, without draught or any inconvenience, exactly the right volume of air at the necessary temperature to every person in the building. Instead of a model institution I found the utmost confusion and ignorance. In a medical ward there was a little wirework object under the beds that looked like a rat-trap. It covered what was stated to be an air outlet and a fan was supposed to draw the air down into an exhaust shaft. But the fan was not working when I tested this supposed outlet. Then, as windows were open close by, the air would go from the window to the outlet in a direct line and only affect the greater part of the ward by an occasional eddy. The temperature at the time of my visit was 62° F. Windows were opened according to the fancy of individuals who knew nothing whatever as to the system of ventilation and seemed quite unaware that it sufficed to open a window to destroy effectively most systems of ventilation. So complete was the confusion that apertures said to be inlets were acting as outlets when I tested them. All this was most disappointing and I could not but wonder whether Dr. Billings is aware how the good work which he has done has been forgotten, neglected, or misapplied.

At the Washington Congress there was also a paper read by Miss Mary E. Lent, graduate of Johns Hopkins Hospital, head nurse of the Instructive Visiting Nurse Association. Miss Lent explained that during the last four years some 3000 tuberculous patients had been visited in their own homes at Baltimore by the nurses of her association. The object of these visits was quite as much to teach as to tend the sick and their families. But "the work of teaching was slow" and "in the case of the very poor it is impossible to teach them to persistently apply the principles of prophylaxis to their daily lives." When this was the case "something more radical had to be done." The nurse should inform the public so that the public might decide on the segregation of patients who were dangerous to the community. Thus spoke Miss Lent at Washington. So here is a picture of some 3000 patients living at Baltimore where they are taught by Miss Lent and her assistant nurses to adopt all kinds of precautions and to make the utmost use of the very slender advantages which, in spite of their poverty, they may enjoy. If, he four general hospitals, two by the General Dispensary, one by the City of Birmingham Aid Society, and one by the Hospital Sunday Fund. The interests of the medical proession are therefore well guarded, for it will always have at least 14 members on the general committee. The fees payable by the members are 5*s.* a year, or 5*d.* a month for each individual, or for every member of a family up to four, and for each additional member of a family above four and residing in the same house 3*d.* per month. The members may make their own selection from the medical staff and every qualified medical man of good repute who does not hold a private club appointment may become a member of the staff. In order that the various provisions above enumerated may become generally known, printed copies of a brief statement of the objects, advantages, and scales of payment are being supplied to the four general hospitals for distribution in the out-patient departments. Similar statements will also be distributed at the seven branches of the General Dispensary, circulars will be sent out to 2000 firms asking them to display notices in placard form in their works, and a circular will be addressed to the members of the medical profession asking them to coöperate and to become members of the staff of the new dispensary.

Dec. 15th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Biennial Dinner of the Clinical School of the University of Liverpool.

THE biennial dinner of the Clinical School connected with the University of Liverpool took place on Dec. 12th, at the Adelphi Hotel, under the chairmanship of Sir James Barr. Among the numerous guests was Sir Dyce Duckworth of London, who proposed the toast of "The Liverpool University and Clinical School." He said, as an old Liverpool man, that the toast appealed to him very warmly. In his early days, long before the University College was founded, there were certain educational establishments in the city, and there were, as there always had been, men of learning and of educational instinct in the city who projected and foresaw what had happened to-day. He could only recall one mistake, as he thought it was, in the city with respect to secondary education, and that was the abolition of his old and venerable school, the Royal Institution, a matter which he had always regretted when he remembered the splendid work which that school performed for the city in forming the characters of some of the most eminent men of the present day. He said that the University of Liverpool must not be a mere technical school for producing engineers or medical men, but an institution for the promotion of learning in its widest sense. He felt sure that the University of Liverpool was founded in a way which was a credit to the city and which would establish it in a position second to none among the universities of the country. As to the Clinical School, he said that he got his clinical experience in the Liverpool hospitals. He saw that they had arranged for the most complete course of clinical instruction in all branches of work, and nothing could be better than that. Colonel Stanton, D.S.O., in replying for the army, said that there were many points on which there was a close sympathy between the medical profession and the army. Referring to the Territorial Army scheme, he said that he was confident that the medical profession would give every assistance to that great undertaking. Speeches were also delivered by the chairman, Sir Edward Russell, Professor John Hill Abram, and others. The dinner was one of the most successful medical gatherings held in Liverpool in recent years.

Winwick Asylum: New Annexe.

The new annexe at Winwick Asylum was formally opened last week by the chairman of the committee, Mr. S. S. Brown. It is intended to accommodate 120 idiot children and 12 adult females, and has cost a little under £22,000. The average cost per bed is thus a little more than £166. The chairman explained that this was an extremely low average. The total cost of the main building was £460,000, which for 2000 patients gave an average cost per bed of £230. Some of the recently built London and Yorkshire asylums cost from £400 to £430 per bed. He hoped the Asylums Board would now consider the advisability of erecting a similar annexe for the accommodation of the girls. Mr. N. W. Helme, M.P., the chairman of the Lancashire Asylums Board, complimented the committee on taking the lead in the care and treatment of the feeble-minded. He endorsed the chairman's hope as to the provision of a new annexe for the girls.

Dec. 15th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

House-flies and Enteric Fever.

IN August last a small epidemic of enteric fever occurred among the staff of the City Hospital for Infectious Diseases. Ten persons in all were affected, one of the resident medical officers, three nurses, and six maidservants being attacked with the disease. It would appear from the histories of the cases that in every case the infection was contracted at or about the same time, and that the very early part of August. In tracing the source of infection some considerable difficulty was encountered. The water-supply of the hospital was good and there was no evidence which would incriminate the milk as it was supplied to the institution, the dairy whence it was obtained was in a generally satisfactory condition, and no cases occurred among the customers of the dairy outside the hospital. The entire staff of the hospital was "tested bacterially" and no "carrier" of the disease was found among those not included in the ten persons above mentioned. Seeing that it was probable that the infection in all these cases was contracted at or about the same time, that the persons affected were all milk-drinkers, and that the infection was not conveyed by "ordinary channels," Dr. H. E. Armstrong, the medical officer of health, has come to the conclusion that the facts quoted, "coupled with that of the swarms of flies during the hot weather at the time, together with the total absence of any other explanation, established the conviction that the infective germs had probably been carried by flies from the enteric pavilion to a bowl of milk in the dairy, and after multiplication these had been distributed and consumed by the members of the staff who afterwards suffered from fever." This outbreak of enteric fever among the staff of the hospital is presumably the origin of the "instructions to the officials on duty in the enteric fever pavilion" which have already been noticed in the columns of THE LANCET. These instructions are valuable so far as they go, but it is noticeable that there is nothing in them which will prevent another outbreak among the administrative and nursing staff similar to the one recorded above. If the passage of flies from the enteric fever pavilion to the dairy was in fact the source of the infection, and Dr. Armstrong is apparently satisfied that it was, it seems desirable that "instructions to the officials having charge of the dairy" should be drawn up and issued. The obvious way to prevent a similar "regrettable incident" occurring in the future would be to take steps to prevent the transit of flies from the enteric fever pavilion to the dairy. This should be easy if the opening into the dairy were fitted with close-mesh wire gauze. It certainly struck one as being very lax administration that in a fever hospital where the danger from flies in enteric fever should be so well known it should be possible for flies to have such easy access to the dairy. Of course, the true source of the infection may have been some quite other cause than flies, though Dr. Armstrong after careful investigation attaches the blame to these insects, but whether or not his conclusion be the right one in this case the opportunity should be taken for issuing more stringent regulations for the control of the dairy.

The Chapel of the Royal Victoria Infirmary.

A special meeting of the house committee of the Royal Victoria Infirmary is to be held on Thursday, Dec. 17th, to discuss matters in connexion with the infirmary chapel. The important business before the meeting will be the consideration of the following proposition to be moved by Dr. G. H. Hume, consulting surgeon to the infirmary. The terms of the motion are:—

> That upon the various points which have arisen in regard to the consecration and user of St. Luke's Chapel it is desirable that a case be stated for the opinion of two eminent counsel in consultation, one an ecclesiastical lawyer and the other a lawyer accustomed to deal with

he four general hospitals, two by the General Dispensary, ne by the City of Birmingham Aid Society, and one by the Hospital Sunday Fund. The interests of the medical profession are therefore well guarded, for it will always have at least 14 members on the general committee. The fees payable by the members are 5*s*. a year, or 5*d*. a month for each individual, or for every member of a family up to four, and for each additional member of a family above four and residing in the same house 3*d*. per month. The members may make their own selection from the medical staff and every qualified medical man of good repute who does not hold a private club appointment may become a member of the staff. In order that the various provisions above enumerated may become generally known, printed copies of a brief statement of the objects, advantages, and scales of payment are being supplied to the four general hospitals for distribution in the out-patient departments. Similar statements will also be distributed at the seven branches of the General Dispensary, circulars will be sent out to 2000 firms asking them to display notices in placard form in their works, and a circular will be addressed to the members of the medical profession asking them to coöperate and to become members of the staff of the new dispensary.

Dec. 15th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Biennial Dinner of the Clinical School of the University of Liverpool.

THE biennial dinner of the Clinical School connected with the University of Liverpool took place on Dec. 12th, at the Adelphi Hotel, under the chairmanship of Sir James Barr. Among the numerous guests was Sir Dyce Duckworth of London, who proposed the toast of "The Liverpool University and Clinical School." He said, as an old Liverpool man, that the toast appealed to him very warmly. In his early days, long before the University College was founded, there were certain educational establishments in the city, and there were, as there always had been, men of learning and of educational instinct in the city who projected and foresaw what had happened to-day. He could only recall one mistake, as he thought it was, in the city with respect to secondary education, and that was the abolition of his old and venerable school, the Royal Institution, a matter which he had always regretted when he remembered the splendid work which that school performed for the city in forming the characters of some of the most eminent men of the present day. He said that the University of Liverpool must not be a mere technical school for producing engineers or medical men, but an institution for the promotion of learning in its widest sense. He felt sure that the University of Liverpool was founded in a way which was a credit to the city and which would establish it in a position second to none among the universities of the country. As to the Clinical School, he said that he got his clinical experience in the Liverpool hospitals. He saw that they had arranged for the most complete course of clinical instruction in all branches of work, and nothing could be better than that. Colonel Stanton, D.S.O., in replying for the army, said that there were many points on which there was a close sympathy between the medical profession and the army. Referring to the Territorial Army scheme, he said that he was confident that the medical profession would give every assistance to that great undertaking. Speeches were also delivered by the chairman, Sir Edward Russell, Professor John Hill Abram, and others. The dinner was one of the most successful medicel gatherings held in Liverpool in recent years.

Winwick Asylum: New Annexe.

The new annexe at Winwick Asylum was formally opened last week by the chairman of the committee, Mr. S. S. Brown. It is intended to accommodate 120 idiot children and 12 adult females, and has cost a little under £22,000. The average cost per bed is thus a little more than £166. The chairman explained that this was an extremely low average. The total cost of the main building was £460,000, which for 2000 patients gave an average cost per bed of £230. Some of the recently built London and Yorkshire asylums cost from £400 to £430 per bed. He hoped the Asylums Board would now consider the advisability of erecting a similar annexe for the accommodation of the girls. Mr. N. W. Helme, M.P., the chairman of the Lancashire Asylums Board, complimented the committee on taking the lead in the care and treatment of the feeble-minded. He endorsed the chairman's hope as to the provision of a new annexe for the girls.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

House-flies and Enteric Fever.

IN August last a small epidemic of enteric fever occurred among the staff of the City Hospital for Infectious Diseases. Ten persons in all were affected, one of the resident medical officers, three nurses, and six maidservants being attacked with the disease. It would appear from the histories of the cases that in every case the infection was contracted at or about the same time, and that the very early part of August. In tracing the source of infection some considerable difficulty was encountered. The water-supply of the hospital was good and there was no evidence which would incriminate the milk as it was supplied to the institution, the dairy whence it was obtained was in a generally satisfactory condition, and no cases occurred among the customers of the dairy outside the hospital. The entire staff of the hospital was "tested bacterially" and no "carrier" of the disease was found among those not included in the ten persons above mentioned. Seeing that it was probable that the infection in all these cases was contracted at or about the same time, that the persons affected were all milk-drinkers, and that the infection was not conveyed by "ordinary channels," Dr. H. E. Armstrong, the medical officer of health, has come to the conclusion that the facts quoted, "coupled with that of the swarms of flies during the hot weather at the time, together with the total absence of any other explanation, established the conviction that the infective germs had probably been carried by flies from the enteric pavilion to a bowl of milk in the dairy, and after multiplication these had been distributed and consumed by the members of the staff who afterwards suffered from fever." This outbreak of enteric fever among the staff of the hospital is presumably the origin of the "instructions to the officials on duty in the enteric fever pavilion" which have already been noticed in the columns of THE LANCET. These instructions are valuable so far as they go, but it is noticeable that there is nothing in them which will prevent another outbreak among the administrative and nursing staff similar to the one recorded above. If the passage of flies from the enteric fever pavilion to the dairy was in fact the source of the infection, and Dr. Armstrong is apparently satisfied that it was, it seems desirable that "instructions to the officials having charge of the dairy" should be drawn up and issued. The obvious way to prevent a similar "regrettable incident" occurring in the future would be to take steps to prevent the transit of flies from the enteric fever pavilion to the dairy. This should be easy if the opening into the dairy were fitted with close-mesh wire gauze. It certainly struck one as being very lax administration that in a fever hospital where the danger from flies in enteric fever should be so well known it should be possible for flies to have such easy access to the dairy. Of course, the true source of the infection may have been some quite other cause than flies, though Dr. Armstrong after careful investigation attaches the blame to these insects, but whether or not his conclusion be the right one in this case the opportunity should be taken for issuing more stringent regulations for the control of the dairy.

The Chapel of the Royal Victoria Infirmary.

A special meeting of the house committee of the Royal Victoria Infirmary is to be held on Thursday, Dec. 17th, to discuss matters in connexion with the infirmary chapel. The important business before the meeting will be the consideration of the following proposition to be moved by Dr. G. H. Hume, consulting surgeon to the infirmary. The terms of the motion are:—

> That upon the various points which have arisen in regard to the consecration and user of St. Luke's Chapel it is desirable that a case be stated for the opinion of two eminent counsel in consultation, one an ecclesiastical lawyer and the other a lawyer accustomed to deal with

likely to prove productive of much annoyance and unjustifiable misrepresentation to the long-suffering dispensary medical officer. He points out that: "It seems to be a frequent practice of members of Pension Committees, to save themselves the odium and trouble of *verifying, or rather falsifying*, the statements of naturally fluent and persuasive applicants, who may often possess *a better knowledge of the Act or how to* come within it than they, to refer all such applicants to the district medical officer, with sometimes the injunction, 'He (the Doctor) can get it (the pension) for you, if he wishes.'" All of us who possess any intimate knowledge of the rural life and medical practice of Ireland recognise the vivid truthfulness of this representation. And as Dr. Greene indignantly—and most justly—asks: "Why endeavour to place more trouble and responsibility on the shoulders of the long-suffering dispensary doctor which he is not legally bound to undertake, when a reference to the relieving officer's or clerk of union's book would settle matters at once. A straightforward and honest statement to these poor and deserving, but most persistent and not always truthful, applicants—'That they cannot obtain any benefit under the Act till it has been changed by Parliament'—would save much time, troubling, and heart-burning." Dr. Greene, who is discussing the defect in the Act with regard to recipients of out-door relief who under the Act are most unjustly excluded from its beneficent provisions, is not only a dispensary medical officer and the holder of an exceptionally large number of other professional appointments, but he is also a magistrate, so that he has had the full opportunities of verifying his data and testing his own opinions.

Death-rates in Irish Towns.

The principal capital cities and seaports of the western Irish counties have been distinguishing themselves during the past week by *the unenviable notoriety* of an enormously high death-rate. Sligo leads off with the startling figure of 43·2, while Limerick and Galway have each exceeded 30. The lowest record was that of Ballymena, which was 4·8, while Tralee (5·3) and Dundalk (8·0) were the only other town areas of which the registration was below 10. The aggregate record of the 22 principal town districts of Ireland for the week was 20·3; the average of the four weeks ending Dec. 5th was 19·6. The highest death-rate from epidemic disease was that of Lisburn (4·5). 16 of the town districts reported no death from epidemics. The average for all Ireland was but 1·0. Two deaths from scarlet fever occurred in Limerick; two from enteric fever in Belfast; while diphtheria accounted for 20 per cent. of the deaths in Lisburn. Dublin had 185 deaths and 196 births; 93 deaths of females outnumbered by one the births of girls (92). The week's record shows a decline in the number of deaths from epidemic disease. 65 of the deaths were of children under five years, 40 being of babies under one year. 51 of the deaths were of persons over 60, while 27 were over 70, *seven over 80, and one over 90* years of age. 63 of the deaths occurred in hospitals and public institutions; five of these were of persons who had been admitted from localities outside the Dublin registration area.

The Queen's University of Belfast.

By the will of the late Mr. M. G. Megaw of London the sum of £1000 is given to the University of Belfast for the purpose of founding scholarships for the sons of farmers.

Infectious Disease in Belfast.

At a meeting of the Belfast public health committee held on Dec. 10th the medical officer of health drew attention to the fact that as compared with other populous centres a very small proportion of the cases of dangerous infectious disease was treated in hospital, notwithstanding the fact that the patients were without proper lodging or accommodation. The department looked to the medical practitioners to recommend cases occurring in their practice where there was not proper accommodation to go into hospital, as the department hesitated putting into force the powers conferred upon it by Section 141 of the Public Health Act; but in the interests of the general public it would be obliged to do so if there was not an improvement. It is really very amusing to hear this appeal made to the medical profession now, when the Ulster Medical Society some years ago sent a deputation to the public health committee objecting to the distance at which it was proposed to locate the fever hospital from the city of Belfast, and pointing out exactly what has since occurred—that the people, that is, the relatives of those ill, would object, owing to the great distance of the hospital (especially in case of their being summoned in an emergency) from the city of Belfast. All this was brought out at the Health Commission, but now the *presence of fever cases in the city is* frightening the authorities who apparently think by appealing to the profession whom they *would not condescend to listen to formerly* they may get their position strengthened.

Ulster Medical Society.

At a meeting of the Ulster Medical Society, held in the Medical Institute, Belfast, on Dec. 10th, Dr. T. S. Kirk, the President, being in the chair, Dr. John Campbell read a communication on Rupture of the Incarcerated Retroverted Gravid Uterus successfully treated, and showed a spleen successfully removed for extensive laceration due to injury. Mr. A. Fullerton read: (1) short notes of a case of Cancer of *the Pylorus, treated by partial gastrectomy; (2) of a case* of Kidney Tumour of suprarenal type; and (3) of a case of Calculus impacted in the ureter with somewhat unusual symptoms. Dr. W. Calwell showed: (1) a specimen of Gastrocolic Fistula which existed without symptoms; (2) a specimen of Calcareous Pleura; and (3) a specimen of Sarcoma of the Lung. Dr. G. A. Hicks showed: (1) a Hydatid Mole; and (2) a Gravid Fallopian Tube removed by operation from a case of repeated extra-uterine fœtation.

Enteric Fever in Londonderry.

There have been three deaths from this epidemic and 15 cases remain under treatment in Foyle Hill Hospital. It is said that the source of infection is the supply from one of the city cowsheds in which a milker had enteric fever. Complicating the outbreak has been a serious shortage of water, and for two days last week a large section of the city was entirely without water. During the great storm of October, the upper reservoir of water was injured, with the result that the water in the middle reservoir became polluted.

Dec. 15th.

PARIS.

(*FROM OUR OWN CORRESPONDENT.*)

The Treatment of Epilepsy.

AT the Hospitals Medical Society on Nov. 27th M. Roubinovitch stated that he had given to four epileptic patients subcutaneous or intramuscular injections of 10 cubic centimetres of cerebro-spinal fluid taken from other epileptics whose fits occurred much less frequently than did their own. Of these four two showed improvement. The fits of one patient were reduced in number from 18 or 20 to four in a month. The other had 60 or 70 fits a month; he was in a very bad state of health and, in fact, half comatose when the injections were commenced. Since Nov. 1st he had only had ten fits, his general condition has improved considerably, and he has partly recovered his intelligence. The two other epileptics who received this treatment only derived very slight and quite transitory benefit from it.

Rabies in Young Dogs.

M. Remlinger brought this subject to the notice of the Biological Society on Nov. 28th. Although rabies is always the result of infection from another rabid animal, and the incubation period is nearly always a long one, the disease occurs in very young animals, even when they are but a *month or two old*. Young puppies are, indeed, much more susceptible to rabies than are grown dogs. The incubation period is distinctly shorter, *sometimes not more than a week*. Puppies, too, are much more dangerous because when they bite they only seem to be playing. As a rule, the virulence of the organism is exalted in its passage through young dogs. When this reinforced virus is inoculated beneath the dura mater of the rabbit it at once becomes a "fixed virus." Hence arises the necessity of early intensive treatment in the case of a bite.

Cinnamate of Sodium in the Treatment of Pulmonary Tuberculosis.

M. Paul Reynier made a communication to the Academy of Medicine *on Dec. 1st* concerning the good results which kely to prove productive of much annoyance and unjustifi-ble misrepresentation to the long-suffering dispensary medi-al officer. He points out that: "It seems to be a frequent ractice of members of Pension Committees, to save themselves he odium and trouble of verifying, or rather falsifying, the tatements of naturally fluent and persuasive applicants, who ay often possess a better knowledge of the Act or how to ome within it than they, to refer all such applicants to the istrict medical officer, with sometimes the injunction, 'He the Doctor) can get it (the pension) for you, if he wishes.'" ll of us who possess any intimate knowledge of the rural ife and medical practice of Ireland recognise the vivid truth-ulness of this representation. And as Dr. Greene indig-antly—and most justly—asks: "Why endeavour to place ore trouble and responsibility on the shoulders of the long-uffering dispensary doctor which he is not legally bound to ndertake, when a reference to the relieving officer's or lerk of union's book would settle matters at once. A traightforward and honest statement to these poor and eserving, but most persistent and not always truthful, pplicants—'That they cannot obtain any benefit under he Act till it has been changed by Parliament'—would ave much *time, troubling, and heart-burning.*" *Dr. Greene*, who is discussing the defect in the Act with regard to recipients of out-door relief who under the Act are most unjustly excluded from its beneficent provisions, is not only a dispensary medical officer and the holder of an exceptionally large number of other professional appoint-ments, but he is also a magistrate, so that he has had the full opportunities of verifying his data and testing his own opinions.

Cinnamate of Sodium in the Treatment of Pulmonary Tuberculosis.

M. Paul Reynier made a communication to the Academy of Medicine on Dec. 1st concerning the good results which e lives of the "infermieri" on duty. The mutiny was not ppressed till the police intervened, one of whom had to end the night with the ringleader who continued, *from the* d *to which he was strapped down, to load him with every* rt of insulting epithet. Incidents of this kind, as I have id, are of scandalously frequent occurrence, varied from ne to time by the flight of dangerous lunatics, after (as ten as not) homicidal assaults on the *personnel* of the ylum. Italy holds too conspicuous a place in the uropean State system not to use every endeavour to bring r charitable institutions up to the standard of her more voured sisters—institutions which, by their very character, ght to be models of peace, of decorum, and of safety.

The Chamber of Deputies has just been debating on the fects or abuses above noted—*taking special cognisance of* e sanitary and medical surveillance of the State prisons. *gnor Romussi, an able and accomplished Milanese repre-* ntative, drew attention to the fact that inadequate *rsonnel* is a prominent factor in the disturbances that have cently characterised prison life, where the conditions all und, including the viands served out, are such as to make the res of the inmates intolerable, with the result that in Milan one the last 13 months have witnessed 19 suicides, effective abortive, among the "detenuti." The local prison has but e medical officer for 1100 convicts and 77 guardians, and is officer is expected to treat all their ailments, to examine em clinically on arrival and departure, with no other help an some casual "infermieri," two of whom are themselves nvicts. The medicaments at his disposal are few and anti- ated, the list being confined to magnesia, castor oil, and vaselina borica," for all the ailments under treatment and s "rimedi generali." The same deficiency is found in the urgical department, there being no "sala d'operazione" operating room) whatever, and *instruments and appliances*, hen wanted, having to be brought from the Ospedale Maggiore! A commission composed of medical men and Members of Parliament is loudly called for, if only to retrieve he good name of Italy throughout Christendom as a leading European Power.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Restricting the Sale of Patent Medicines in Canada.

IT has been ordained by the Dominion Government that the federal law passed at the last session of the Canadian Parliament will come into force on April 1st, 1909. This Proprietary Medicine Act will prohibit absolutely the sale of patent medicines which contain cocaine or any *of its salts* and preparations. With regard to other drugs, such as morphine, opium, and so on, the sale may be made but under very close restrictions. Every manufacturer, importer, or agent must see to it that when the medicine is sold there is printed conspicuously on the bottle or label or box a formula setting forth the drugs *contained*, the amount, and the name and address of the vendor. There is, however, an alternative to this procedure. The manufacturer may transmit directly to the Department of Inland Revenue at Ottawa the formula showing what ingredients are contained therein and obtain from it a certificate to the effect that the preparation does not contain such a proportion of the drug as to be injurious to health. The use of the certificate as bearing on the merits of the preparation is forbidden and a penalty is provided. Before the Act comes into force the 3000 druggists in Canada must register their businesses with the Department of Inland Revenue and also the formula for each preparation which they put up. Almost every druggist in Canada puts forth a preparation or preparations of his own, and this means that he must either publish the formula of all on each parcel or submit and register it in the Inland Revenue Department of the Canadian Government. All druggists manufacturing a patent medicine must obtain from the Department Inland Revenue stamps, and if they sell any of their preparations without one of these selfsame stamps affixed thereto the penalty for the first offence will be $50.

The Experience of the Hospital for Sick Children, Toronto, in Broncho-pneumonia.

Dr. C. S. McVicar, of the Hospital for Sick Children, Toronto, reports the experience of that institution in the past seven years with broncho-pneumonia, in the November issue of the *Dominion Medical Monthly*. During those years 75 cases were admitted to the medical wards of the institution: primary, 64; secondary, 11. The deaths from the former were 25, 39 per cent.; from the latter 8, 73 per cent. 38 per cent. of the cases occurred in winter, 25 per cent. in spring, 24 per cent. in autumn, and 13 per cent. in summer, the month of greatest incidence being February. The character of the temperature was remittent in 56, or 75 per cent.; continuous in 19, or 25 per cent. In 42 cases with recovery, decline was by lysis in 29 cases, or 69 per cent.; by crisis in 13, or 31 per cent. Cough was present in 75 cases; cyanosis was noted in 61 cases, or 80 per cent. In 39 primary cases with recovery the average maximum temperature was 104° F.; *average maximum pulse, 153*; average maximum respiration, 58. In 25 primary cases with death these ranged as follows: 104°, 161, 68. From the experience of this hospital it is inferred that the increased respiration-rate is the most serious feature in determining the prognosis. In the whole series of 75 cases the temperature rose above 106° in four cases—three with death and one with recovery. Eight cases with recovery were treated without stimulation or local application of any sort. 18 cases with recovery were treated without stimulation. Anti-pyretic drugs were used in five cases, of which two died and three recovered. Hydrotherapy has proved of the greatest value. The child was always given as much fluid by the mouth as he or she would take. The hot pack was found to be the best external means of controlling nervous symptoms and it seldom failed to keep the temperature within bounds. Cold packs and cold sponging are not to be recommended as they are distressing to the patient. Local applications of any kind did not seem to be of any benefit. For cardio-vascular *distress* strychnine and whisky were used in 57 cases. The whisky seemed to exert the greatest benefit because of its action as a cerebral sedative. No benefit could be put down to the use of expectorants. Belladonna or atropine was used in nine cases; no results ensued except in three cases, as an anti-spasmodic in cough. *Oxygen* was used in 19 cases, 10 of which were fatal. In the nine cases with recovery the severity of the cases is shown by the average maximum temperature, pulse, and respiration as follows: 104°, 163, 64. Dr. McVicar gives it as his opinion from his experience that oxygen inhalations are more useful than any other treatment in this disease.

Special Meeting of Ontario Medical Council.

There was held during the month of November in Toronto a special meeting of the Ontario Medical Council called to consider and to advance in the matriculation standard the question of inter-provincial reciprocity, the question of reciprocity with Great Britain, and as well the question for erasing from the Register the names of certain members of the College who had recently been before the Ontario courts for alleged criminal practices. The Council affirmed its opinion in inter-provincial reciprocity to this extent, that wherever a similar high standard existed as in Ontario reciprocal relations might be entered into. As regards reciprocity with Great Britain it did not at the present time see its way clear to establish that condition of affairs. The percentages for passing its examinations were raised but the matriculation examination will remain as at present, although in the near future it will most likely be raised to the standard of senior matriculation in the universities. Regarding the charges of unprofessional conduct *brought against* practitioners it was thought wise in view of the fact that one case has not yet been finally disposed of by the courts that no steps should be taken in the matter at the present time. One outcome, however, *of this is* a circular letter addressed by the Council's prosecutor to the county attorneys throughout the province requesting that wherever Members of the College of Physicians and Surgeons are before the courts charged with unprofessional conduct in respect of criminal practices the Council should be advised of the same promptly.

Tuberculosis Exhibition in Montreal.

Montreal is just closing a most successful tuberculosis exhibition which opened in that city on Nov. 18th. The opening *ceremonies took place* with Sir George Drummond presiding. The Mayor of Montreal delivered an address of welcome; the Hon. Mr. Gouin, Premier of Quebec, did likewise for the province of Quebec. Professor J. George Adami and Dr. E. P. *Lachapelle* introduced the Governor-General, e lives of the "infermieri" on duty. The mutiny was not ppressed till the police intervened, one of whom had to end the night with the ringleader who continued, from the d to which he was strapped down, to load him with every rt of insulting epithet. Incidents of this kind, as I have id, are of scandalously frequent occurrence, varied from ne to time by the flight of dangerous lunatics, after (as ten as not) homicidal assaults on the *personnel* of the ylum. Italy holds too conspicuous a place in the uropean State system not to use every endeavour to bring r charitable institutions up to the standard of her more voured sisters—institutions which, by their very character, ght to be models of peace, of decorum, and of safety.

The Chamber of Deputies has just been debating on the fects or abuses above noted—taking special cognisance of e sanitary and medical surveillance of the State prisons. gnor Romussi, an able and accomplished Milanese representative, drew attention to the fact that inadequate *rsonnel* is a prominent factor in the disturbances that have cently characterised prison life, where the conditions all und, including the viands served out, are such as to make the res of the inmates intolerable, with the result that in Milan one the last 13 months have witnessed 19 suicides, effective abortive, among the "detenuti." The local prison has but ie medical officer for 1100 convicts and 77 guardians, and is officer is expected to treat all their ailments, to examine em clinically on arrival and departure, with no other help ian some casual "infermieri," two of whom are themselves onvicts. The medicaments at his disposal are few and antiuated, the list being confined to magnesia, castor oil, and vaselina borica," for all the ailments under treatment and s "rimedi generali." The same deficiency is found in the urgical department, there being no "sala d'operazione" operating room) whatever, and instruments and appliances, hen wanted, having to be brought from the Ospedale Maggiore! A commission composed of medical men and Members of Parliament is loudly called for, if only to retrieve the good name of Italy throughout Christendom as a leading European Power.

Dec. 6th.

(FROM OUR OWN CORRESPONDENT.)

Restricting the Sale of Patent Medicines in Canada.

IT has been ordained by the Dominion Government that the federal law passed at the last session of the Canadian Parliament will come into force on April 1st, 1909. This Proprietary Medicine Act will prohibit absolutely the sale of patent medicines which contain cocaine or any of its salts and preparations. With regard to other drugs, such as morphine, opium, and so on, the sale may be made but under very close restrictions. Every manufacturer, importer, or agent must see to it that when the medicine is sold there is printed conspicuously on the bottle or label or box a formula setting forth the drugs contained, the amount, and the name and address of the vendor. There is, however, an alternative to this procedure. The manufacturer may transmit directly to the Department of Inland Revenue at Ottawa the formula showing what ingredients are contained therein and obtain from it a certificate to the effect that the preparation does not contain such a proportion of the drug as to be injurious to health. The use of the certificate as bearing on the merits of the preparation is forbidden and a penalty is provided. Before the Act comes into force the 3000 druggists in Canada must register their businesses with the Department of Inland Revenue and also the formula for each preparation which they put up. Almost every druggist in Canada puts forth a preparation or preparations of his own, and this means that he must either publish the formula of all on each parcel or submit and register it in the Inland Revenue Department of the Canadian Government. All druggists manufacturing a patent medicine must obtain from the Department Inland Revenue stamps, and if they sell any of their preparations without one of these selfsame stamps affixed thereto the penalty for the first offence will be $50.

The Experience of the Hospital for Sick Children, Toronto, in Broncho-pneumonia.

Dr. C. S. McVicar, of the Hospital for Sick Children, Toronto, reports the experience of that institution in the past seven years with broncho-pneumonia, in the November issue of the *Dominion Medical Monthly*. During those years 75 cases were admitted to the medical wards of the institution: primary, 64; secondary, 11. The deaths from the former were 25, 39 per cent.; from the latter 8, 73 per cent. 38 per cent. of the cases occurred in winter, 25 per cent. in spring, 24 per cent. in autumn, and 13 per cent. in summer, the month of greatest incidence being February. The character of the temperature was remittent in 56, or 75 per cent.; continuous in 19, or 25 per cent. In 42 cases with recovery, decline was by lysis in 29 cases, or 69 per cent.; by crisis in 13, or 31 per cent. Cough was present in 75 cases; cyanosis was noted in 61 cases, or 80 per cent. In 39 primary cases with recovery the average maximum temperature was 104° F.; average maximum pulse, 153; average maximum respiration, 58. In 25 primary cases with death these ranged as follows: 104°, 161, 68. From the experience of this hospital it is inferred that the increased respiration-rate is the most serious feature in determining the prognosis. In the whole series of 75 cases the temperature rose above 106° in four cases—three with death and one with recovery. Eight cases with recovery were treated without stimulation or local application of any sort. 18 cases with recovery were treated without stimulation. Antipyretic drugs were used in five cases, of which two died and three recovered. Hydrotherapy has proved of the greatest value. The child was always given as much fluid by the mouth as he or she would take. The hot pack was found to be the best external means of controlling nervous symptoms and it seldom failed to keep the temperature within bounds. Cold packs and cold sponging are not to be recommended as they are distressing to the patient. Local applications of any kind did not seem to be of any benefit. For cardio-vascular distress strychnine and whisky were used in 57 cases. The whisky seemed to exert the greatest benefit because of its action as a cerebral sedative. No benefit could be put down to the use of expectorants. Belladonna or atropine was used in nine cases; no results ensued except in three cases, as an anti-spasmodic in cough. Oxygen was used in 19 cases, 10 of which were fatal. In the nine cases with recovery the severity of the cases is shown by the average maximum temperature, pulse, and respiration as follows: 104°, 163, 64. Dr. McVicar gives it as his opinion from his experience that oxygen inhalations are more useful than any other treatment in this disease.

Special Meeting of Ontario Medical Council.

There was held during the month of November in Toronto a special meeting of the Ontario Medical Council called to consider and to advance in the matriculation standard the question of inter-provincial reciprocity, the question of reciprocity with Great Britain, and as well the question for erasing from the Register the names of certain members of the College who had recently been before the Ontario courts for alleged criminal practices. The Council affirmed its opinion in inter-provincial reciprocity to this extent, that wherever a similar high standard existed as in Ontario reciprocal relations might be entered into. As regards reciprocity with Great Britain it did not at the present time see its way clear to establish that condition of affairs. The percentages for passing its examinations were raised but the matriculation examination will remain as at present, although in the near future it will most likely be raised to the standard of senior matriculation in the universities. Regarding the charges of unprofessional conduct brought against practitioners it was thought wise in view of the fact that one case has not yet been finally disposed of by the courts that no steps should be taken in the matter at the present time. One outcome, however, of this is a circular letter addressed by the Council's prosecutor to the county attorneys throughout the province requesting that wherever Members of the College of Physicians and Surgeons are before the courts charged with unprofessional conduct in respect of criminal practices the Council should be advised of the same promptly.

Tuberculosis Exhibition in Montreal.

Montreal is just closing a most successful tuberculosis exhibition which opened in that city on Nov. 18th. The opening ceremonies took place with Sir George Drummond presiding. The Mayor of Montreal delivered an address of welcome; the Hon. Mr. Goun, Premier of Quebec, did likewise for the province of Quebec. Professor J. George Adami and Dr. E. P. Lachapelle introduced the Governor-General, ecialty but also widely read in the various branches his profession. His scientific contributions to the rious medical societies gained for him the esteem and gard of the leading men in neurology and allied branches, that all who knew him felt that it was an honour well served when he was elected president of the Neurological ction of the Royal Society of Medicine, an office that he led with distinction and dignity, alas, for so very short a me. The Medical Society also was glad to bestow office d honours on him, for he was Lettsomian lecturer in their st session and worthily upheld the great traditions of that st. He was also intimately connected with the internal onomy of that society as one of their trustees. At the mmencement of the last meeting of the members the esident, Mr. C. B. Lockwood, in an eloquent appreciation Dr. Beevor's services, pointed out that not only was he ustee for the real estate of the Medical Society of London at had been also one of their honorary secretaries, and was nown personally to almost all their members. Mr. Lockood, speaking as one who had been for many years one of r. Beevor's colleagues at the Great Northern Central ospital, found it unnecessary to speak of Dr. Beevor's prossional distinctions, but bore eloquent testimony to his alities as a courteous, pleasant colleague or friend, and a man who performed all the duties which he underok in a most painstaking manner, sympathetic words which lmirably expressed the feelings of those present.

In addition to the distinctions mentioned, Dr. Beevor was oonian lecturer to the Royal College of Physicians of ndon in 1903, when he took as his subject Muscular Movements and their Representation in the Central Nervous stem.[1] One of the most remarkable and valuable of the any contributions to medical literature by Dr. Beevor was s work on the distribution of the different arteries supplyg the brain published in the Philosophical Transactions of e Royal Society of London of this year. This work was dertaken to ascertain the area of distribution of the fferent arteries of the brain, when they were injected multaneously under the same pressure with gelatin conining soluble colours in place of the usual method of jecting the arteries singly and successively with insoluble lours held in suspension. He succeeded in the difficult sk of injecting simultaneously five arteries of the brain on e same side—viz., the anterior, middle, and posterior rebrals, the anterior choroidal, and the posterior communicating arteries—with naphthol green, carmine, icholson's blue, acridin yellow, and Bismarck brown spectively. The method employed gave such exact sults and a differentiation so definite that Dr. Beevor as able by means of coronal sections to show that e corpus subthalamicum (Luy's body) had a double terial supply sometimes, its superior external part being jected by the posterior communicating artery, while its ternal inferior part was injected by the posterior rebral artery. The fact, therefore, that so small body as the corpus subthalamicum can receive s blood-supply from two different arteries is against e theory hitherto advanced that the arrangement of the ood-supply has a functional significance, as Dr. Beevor's vestigation shows the blood-supply to be purely anatomical d not distributed according to the physiological action of e part. By this method Dr. Beevor exactly determined e blood-supply to the different parts of the corpus llosum, especially of its posterior constituents, and experiment the direction of the flow of blood the posterior communicating artery has been found be from the carotid to the posterior cerebral tery. To sum up the value of this work of Dr. eevor very briefly, it may be said that until his work was blished there was no book which gave a description of the terial supply to all parts of the brain. The accurate owledge of the area of supply of any particular tery is not only of importance from the point of ew of anatomy but it is also of great value from the athological side, as it is necessary to know for the purposes diagnosing disease the exact portion of the brain hich is liable to undergo softening when any particular tery is blocked by a clot of blood.

In his private life Dr. Beevor gained the affection and teem of all who knew him, and his musical gifts and artistic abilities rendered him as popular as he was beloved for his amiability and gentleness. He leaves a widow, a son, and a daughter to mourn their loss, and to them in their bereavement we tender our sympathy, hoping that the knowledge that this brief record of the life and work of a good and learned man summarises the feelings of all his friends and fellow-workers will do something to lessen their pain.

"C. A. B.," a friend and colleague, writes the following graceful appreciation: "Charles Beevor is dead, dead ere his prime, and I mourn the loss of a dear and steadfast friend and colleague. I have known him intimately for 25 years, ever since, indeed, he was engaged in an experimental research with Horsley on the minute representation of movement in the cerebral cortex and internal capsule. From that time till the day of his death he was working hard and patiently on various problems connected with that special department of medicine to which he had devoted his life. Only recently the Royal Society has published a beautiful monograph by Beevor on the arterial supply of the brain, and if ever its Fellowship is awarded to a dead man it should be given to my dead friend. On Wednesday last I was dining in Beevor's company. He accompanied me home. His bright and kindly talk about his colleagues and their work, combined with quaint touches of humour, were a delight, and I shall never forget that evening with him. His death to me is an irreparable loss. Beevor's character was singularly winning and attractive. Sweet, simple, guileless, unselfish, retiring, and affectionate; none who knew him as I did could help loving him. No breath of slander ever passed his lips. His mind and thoughts were white and clean as those of a child. He never uttered an unkind word. It is most difficult to convey in words an adequate idea of the simplicity and beauty of Beevor's life. Perhaps in this endeavour I may detach and adapt a few lines from a beautiful poem by Macaulay. The fairy queens that ruled the life of Beevor were not the busy elves—gain, fashion, pleasure, power—

'to whose domain
Belongs the nether sphere, the fleeting hour.'

He let them go—

'Without one envious sigh, one anxious scheme.'

. . . . . .

'But, when those wayward sprites had passed away,
Came One, the last, the mightiest, and the best.
That glorious lady, with the eyes of light
And laurels clustering round her lofty brow.'

. . . . . .

'Fortune, that lays in sport the mighty low,
Age, that to penance turns the joys of youth,
Shall leave untouched the gifts which she bestows,
The *sense of beauty* and the *thirst of truth*.'

That glorious spirit who bestows these gifts ruled Beevor's life. He—

'through all change
Fixed his firm gaze on virtue and on her.'"

JOHN DAVID HILLIS, F.R.C.S. IREL., M.R.C.P. & L.M. IREL.

Mr. J. D. Hillis, who was one of the most popular and highly respected of Dublin suburban practitioners, died suddenly and quite unexpectedly on Dec. 8th, at his residence, 10, Leinster-square. Up to the hour of the fatal attack of "failure of the heart" the deceased gentleman was actively engaged in his professional duties. He was of English birth and parentage but received his professional education at the School of Surgery of the Royal College of Surgeons in Ireland, of which corporation he became a Licentiate in 1867. In the same year he received the diplomas of Licentiate and Licentiate in Midwifery of the (King and Queen's, now) Royal College of Physicians of Ireland. He secured an appointment soon after obtaining these qualifications in the Government Medical Service, British Guiana. His sojourn in Demerara in charge of a lepers' hospital gave him rare opportunities of observing a loathsome—and still decidedly mysterious—disease. One of the special results was the production of a volume, after retiring from the Government service and obtaining a pension, bearing the title, "Leprosy in British Guiana: An Account of West Indian Leprosy." It was published in 1881, after its author had settled in Dublin. It is illustrated by 20 lithographic plates and gives one of the most graphic accounts of the disease which have hitherto appeared in the English language. The continuation of his interest in the subject pecialty but also widely read in the various branches f his profession. His scientific contributions to the arious medical societies gained for him the esteem and egard of the leading men in neurology and allied branches, o that all who knew him felt that it was an honour well leserved when he was elected president of the Neurological ection of the Royal Society of Medicine, an office that he illed with distinction and dignity, alas, for so very short a ime. The Medical Society also was glad to bestow office nd honours on him, for he was *Lettsomian lecturer* in their ast session and worthily upheld the great traditions of that ost. He was also intimately connected with the internal conomy of that society as one of their trustees. At the ommencement of the last meeting of the members the resident, Mr. C. B. Lockwood, in an eloquent appreciation f Dr. Beevor's services, pointed out that not only was he rustee for the real estate of the Medical Society of London ut had been also one of their honorary secretaries, and was known personally to almost all their members. Mr. Lockwood, speaking as one who had been for many years one of Dr. Beevor's colleagues at the Great Northern Central Hospital, found it unnecessary to speak of Dr. Beevor's professional distinctions, but bore eloquent testimony to his qualities as a courteous, pleasant colleague or friend, and as a man who performed all the duties which he undertook in a most painstaking manner, sympathetic words which admirably expressed the feelings of those present.
